Dr. Sprengle, of Dresden, thought that in many cases there would be absorption of the pus if we waited for it, and if we opened the abscess it was best to do it with an aspirator or fine trocar.

Dr. Lange, of New York, spoke of the constitutional treatment along with the surgical, and thought that he would not open these abscesses if he could avoid it until after the acute stage had passed.

Dr. Chavasse, of Birmingham, England, thought it best to open these abscesses as soon as possible and give the sufferers a chance.

A paper on "The Removal of Sequestra by Solution in Acid," by Edmund Andrews, M. D., of Chicago, was then read. In this paper the author gave his experiments in detail, and related a number of cases in which sequestra had been removed by the use of acids, without operation. He recommends that hydrochloric acid be used of a strength a little weaker than the official dilute acid.

Section in Psychological Medicine.

Professor Mendel, of Berlin, read the opening paper on "The Origin of the Upper Facial Nerve."

Dr. E. A. Homan, of Helsingfors, Finland, then read a paper on "The Histological Alterations Following Amputations in the Peripheral Nerves, the Spinal Ganglia, and the Marrow." His conclusion was that the posterior nerve-roots had sensory function, inasmuch as the cell-group of the posterior

column atrophies when only the posterior roots were eliminated.

Dr. Otto presented a paper on "Nucleus-staining by Analine Dyes."

Dr. J. Langdon Down, of London, England, read a paper on "Cases Illustrating the Association of the Prow-shaped Cranium with Neurotic Disease."

At the afternoon session, the time was occupied with a discussion of "Syphilis in its Relations to Insanity," and subsequently the section took up the subject of "Insanity Due

to Acute Syphilis;" "Syphilis Producing Epilepsy, with or without Insanity;" "Progressive Weak-mindedness," and "The General Pathology of Cases of Insanity with Syphilis."

These subjects were discussed at considerable length by Dr. Savage, of London, and also by Drs. Spitzka, Hughes, Channing, Hurd, Godding, Fergusson, and Gundry.

The section closed after Dr. Ingram, of Washington, D. C., read his paper on "Gun-shot-wound of the Spinal Cord."

EDITORIAL DEPARTMENT.

PERISCOPE.

A Form of Infectious Broncho-Pneumonia of Intestinal Origin.

At certain times, especially during the hot summer months and in November, Sevestre says attacks of pneumonia frequently occur in children 1 or 2 years of age, which are marked by a very typical course, and by a disposition to spread epidemically or endemically. The disease begins as a diarrhoea without fever; the stools are pretty numerous—six to ten a day—contain much undigested food and are particularly foul. After two to five or six days, cough appears and simultaneously fever, the temperature ranging generally between 102°–104° F. Physical signs show a bronchitis or broncho pneumonia. In mild cases the fever subsides after two or three days and convalescence begins. More frequently the course is a severe one, and a fatal issue very common. Death occurs with typhoid symptoms or in collapse. Before death, pemphigus-like eruptions often appear upon the skin. At autopsies are found signs of an intense enteritis in the large or small intestine, or in both together. In the diseased parts the solitary glands and especially Peyer's patches, are markedly swollen, but never proceed to the formation of true ulcers. Contrary to the condition in typhoid fever, the changes in the follicles are tolerably well developed throughout the whole small intestine.

The broncho-pneumonic foci are very small, almost always have their seat near the surface of the lungs, and their periphery is surrounded by a network of enlarged lymphatic vessels. The bronchial glands are always swollen. The spleen is not changed, but the liver is frequently in a condition of a tty degeneration.

Investigation shows that for the most part the attacks have begun in dietary indiscretions, and the author thinks that the entire symptoms of the disease owe their origin to an infection arising from the intestine, and that the affection of the lung in particular is explained by extension of the poison from the intestine to the lung by way of the lymph vessels. The most effective medication is the employment of disinfectants by the mouth, and for this purpose calomel in doses of 1½–3 grs. a day is of especial service. *Centralblatt f. d. med. Wissensch.*, Aug. 13th, 1887.

Two Cases of Traumatic Hernia of the Diaphragm.

In one case a deep wound was inflicted with a pair of shears in the sixth left intercostal space in the mammary line, which wound had occasioned a diaphragmatic hernia. At the autopsy a coil of intestine was found in the left pleural cavity, which extended up to the second rib, while the lung was pressed upwards and backwards. At every breath of the patient a gurgling sound was heard, which was so loud that it was plainly audible outside of the room. In a second case in which the hernia had been produced by means of a stab in the same place, the same loud murmur was to be heard. —*Deutsche Medizinisch-Zeitung*, August 22d, 1887.

Salicylate of Soda in Gonorrhœal Orchitis.

In a Paris thesis, salicylate of soda is extolled as nearly a specific in gonorrhœal orchitis. At the end of some hours there will already be a diminution of the pain, which disappears completely a short time afterwards.

But it is in the acute cases of epididymitis accompanied by inflammation of the tunica vaginalis that the treatment is especi-

ally efficacious. It is without effect if the prominent symptom is inflammation of the cord.

Besides, in the cases treated by the salicylate, the resolution of the swelling is more rapid and can be attained in from eight to ten days, and after a day or two the patient can get up. The remedy is recommended for its simplicity and harmlessness.—*Revue Médicale*, June, 1887.

Therapeutics of Hyosine.

Concerning the use and value of hyosine, Erb (*Therap. Monatshefte*) reports that he has found the three salts of (H. hydroidicum, hydrobromicum, hydrochloricum) of about equal value, and that he has given them in doses of $\frac{1}{75}$ — $\frac{1}{200}$ gr. Among its useful qualities, he shows that the remedy acts as an energetic check on the salivary secretion, and can be used with advantage as a temporary cure in salivation; that in many cases it is an effective hypnotic; that it is an especially useful drug in paralysis agitans, inasmuch as when given in small doses ($\frac{1}{75}$ — $\frac{1}{125}$ gr.), it usually allows the patients the free use of their limbs for several hours, and in many stops the tremor for the time being. In spasms of single muscles, or groups of muscles, the remedy is of value. Caution must be exercised in giving the drug, as many patients possess a marked intolerance for it, and show poisonous effects even from small doses.

The Gastric Juice in Acute Poisoning by Phosphorus.

A dog which had been fed for a long time exclusively upon meat was poisoned with phosphorus, and when the toxic symptoms were strongly developed, pepper suspended in water was introduced into the stomach; and then after the dog was allowed to bleed to death, the contents of his stomach were investigated. In the latter were found a volatile acid .09, lactic acid 2.07, and hydrochloric acid 2.12 parts per thousand, although the glands of the stomach were in an advanced stage of fatty degeneration. Another dog, which on the sixth day after

the poisoning, yielded suddenly to the poison, and showed marked icterus and severe degeneration of the stomach, liver, etc., had in the stomach a strongly reacting volatile acid, .03 per thousand, 1.12 hydrochloric acid and possibly some other vegetable acid. In both cases the contents of the stomach contained peptone and in an infusion of the mucous membrane, the fibrin continued pretty well marked. There is therefore also in lethal phosphorus poisoning, neither the stoppage of the production of hydrochloric acid nor of active pepsin. Upon stimulation, the mucous membrane of the stomach so severely injured by the phosphorus, responds by the secretion of a considerable amount of hydrochloric acid.—*Centralblatt f. d. med. Wissensch.*, No. 30, 1887.

Congenital Myomas.

Kolisko describes several small nodules in the heart of a boy two months old who died suddenly. Microscopic tests showed that they were tumors consisting transversely striated muscular fibres of a peculiar cavernous arrangement. In the literature the author found five parallel cases recognized as rhabdomyomas, though only three of these were actually parallel cases, while he sought to demonstrate that both the others were false rhabdomyomas. Proceeding from Cohnheim's theory of tumors, he busied himself with the investigation of the heart of embryos and found in a human embryo about four weeks old, a formation similar to that in his cavernous myoma of the heart. Thereupon the author concluded that the structure of rhabdomyoma corresponds with that of the heart muscle in the earliest stages of development, and that these tumors therefore, have a congenital origin.—*Centralblatt f. d. med. Wissensch.*, July 30, 1887.

The Relative Proportion of Sugar in Venous Carotid and Portal Blood of Animals.

Seegen's researches upon the production of sugar in the liver having been criticized by Dr. Abeles in a preliminary communication to the Society of Physicians of Vienna, Seegen repeated his experiments, using Stricker's method, with the assistance of Drs. Gaertner and Ikalowicz. The first seven experiments were made upon animals narcotized with chloroform, the last five upon non-narcotized animals. The author gives a tabular view of his experiments, and then gives the following as the first part of his results: 1. Without exception the venous blood of the liver contains more sugar than carotid or

portal blood. The average of seven experiments shows for carotid or portal blood .139 per cent. sugar, and for venous blood, .196 per cent. The difference in favor of venous blood is about 40 per cent. It is entirely proper that this difference should be less than that obtained by other methods. According to the first method the excess of sugar in venous blood was on the average 83 per cent., and according to the second method the excess of sugar in venous blood is 68 per cent. over the amount of sugar of the portal blood.—*Centralblatt f. d. med. Wissensch.*, July 30, 1887.

Treatment of Delayed Union in Fractures.

Dr. Helferich pointed out to the Congress of German surgeons the following procedure, designed to promote the formation of new bone.

It consists in applying a tube of caoutchouc circularly around the limb, beneath the seat of the lesion; the tube is moderately tight and is kept there for an hour at first, then gradually longer and longer.

The venous hyperæmia thus produced, occasions an ossifying periostitis, and increases the osseous regeneration. Besides the cases of pseudo-arthritis and those in which the formation of callous is simply delayed after fracture, the method is applicable to the treatment of osteomyelitis and of necrosis, when the osseous regeneration is insufficient, and in fractures called spontaneous.

The author thinks that it ought to be tried likewise for the purpose of increasing the length of the bone after luxations or fractures that have healed with shortening. It is useful in infantile paralyses that involve shortening of the limb, but it is contra-indicated in tuberculous or benign affections of the bone and when there are extensive granulating wounds.

The constriction not being very great there is no reason to fear the development of varicose veins; besides the hyperæmia can be limited to certain regions by exercising compression upon the rest of the limb by means of bandages.—*Revue Médicale*, June, 1887.

Philadelphia: P. Blakiston, Son and Co., 1887. Price, \$1.50.

This book contains an interesting account of the history of Massage, some of which is rather apocryphal. This is followed by an account of the various movements included in this method of treatment and the way in which they are carried out. This account is far from elaborate, and one may realize how little the author would expect it to be considered complete when we say that it covers only twenty-three pages, and that the author declares that the art of massage cannot be acquired in less than two years.

Dr. Murrell is a strong believer in the value of massage, and describes in an enthusiastic and agreeable manner the way it should be carried out, the persons by whom it should be practiced, its mode of action, and the conditions to which it is applicable.

As a whole, this book is both interesting and instructive, and a careful perusal of it would correct some widespread errors as to what massage really is.

Surgical Emergencies, Together with the Emergencies Attendant on Parturition, and the Treatment of Poisoning. By William Paul Swain, F. R. C. S., Surgeon to the South Devon and East Cornwall Hospital (England), etc. Fourth edition. 8 vo. xvi., pp. 229. Philadelphia: P. Blakiston, Son & Co., 1887. Price, \$1.50.

In examining this new edition of an old acquaintance, we find the previous excellent suggestions modified to a certain extent so as to bring them up to the level of the improvements which experience has suggested since the appearance of the first edition.

We observe that some of these improvements have been appropriated without that acknowledgment which their originators would probably be pleased to have—for example, Sayre's adhesive plaster dressing for fracture of the clavicle.

We doubt if Mr. Victor Horsley would altogether approve of the suggestions for the treatment of the wound in cases of trephining; and Professor Krönlein would probably wish to add something to the recommendation for the treatment of hemorrhage of the meningeal artery.

Notwithstanding these minor criticisms, we have no hesitation in recommending this book as likely to be useful in emergencies, and especially to practitioners who have not a large library.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

GONORRHOEA IN WOMEN.

Authorities on venereal diseases are still at variance as regards the question whether gonorrhœa is a specific disease or not. On the one side it is held that gonorrhœa is a non-specific inflammation of the urethra or vagina, as the case may be, in no respect differing from an inflammation of the same parts produced by, for instance, the passage of a sound or the application of caustics; on the other side it is regarded as a specific inflammation, produced by a special micro-organism called the gonococcus, which has been isolated and cultivated, and with which, it has been claimed, a true gonorrhœal ophthalmia can be produced. These are the two extreme views of the pathology of the disease.

The *Manchester Medical Chronicle* has been publishing a paper, which is yet incomplete, upon Gonorrhœal Infection in Women. This paper is by Dr. W. J. Sinclair, who is Honorary Physician to the Manchester Southern Hospital for Women and Children, and it is an able and instructive clinical contribution toward settling the question just referred to. Dr. Sinclair asserts that, strictly speaking, there is no vaginal gonorrhœa, but that the disease attacks the uterus from the start. Therefore, in examining discharges for the gonococcus, specimens should be taken from the orifice of the urethra, from the neck of the uterus, and in exceptional cases, from the orifices of Bartholini's glands, and the case should be as recent as possible.

By far the most valuable part of the paper is that in which he shows the dangers which result to the woman from latent gonorrhœa in the husband. There is no doubt, in Dr. Sinclair's mind, that the disease in the male may be latent until evoked by excesses after marriage. Moreover, he thinks gonorrhœa may be latent in a woman also, and be transferred to her second husband after marriage. These are very important points for the doctor to bear constantly in mind. For while fear of the consequences will in all probability never keep a man chaste, yet we cannot help thinking that a man will have sufficient regard for the woman whom he has chosen as his future wife, not to marry until his physician can assure him that danger of infecting his wife is past.

The morbid changes that are produced in the uterus and appendages from slight chronic gleet or latent gonorrhœa are already well known, but from their importance deserve brief enumeration. They consist in a slowly progressing parametritis, which results in fixation of the uterus on one or both sides; and in a slowly progressing inflammatory process in the tubes, which occludes them and stiffens and binds down their frimbriated extremities. In other words, barrenness is the almost invariable sequel. Besides, the woman is doomed to a more or less continuous invalidism, with periodical exacerbations of distress at the menstrual periods.

If the infection occur in an acute stage of gonorrhœa, the woman may develop acute suppuration of the tube and ovary, with subsequent formation of abscesses, as the author shows from a reported case.

BURIAL OR CREMATION.

While some may think at first that the subject of disposition of the dead is beyond the province of the physician, he will on second thought see that from a sanitary point of view it may become of great concern to him, especially if he is a practitioner in a large city. As population increases, both the number of deaths increases, and at the same time the demand for ground for all kinds of building purposes. The commercial aspect of this question, however, is not one that we desire to speak of here, if, indeed, it can be successfully urged anywhere. But what effect has the presence of cemeteries upon the health of communities? This, according to Dr. Frederick Lowndes, in a paper read before the British Medical Association at its recent meeting at Dublin (*Medical Press and Circular*), depends largely upon the manner of the burial. Vaults and leaden coffins are to be unequivocally condemned, because they permit of the accumulation and retention of water. As the result of his experiences in witnessing the removal of portions of four burying grounds and the whole of a fifth in Liverpool, Mr. Lowndes declared that many of the churchyards of England were masses of boxed-up putridity, and that the dead could not be regarded as properly buried at all. He considered that cremation was, in a scientific point of view, the most perfect method of disposing of the dead, and was particularly to be commended during the prevalence of epidemics; but thought that public sentiment was so much against it that there was slight prospect of its being generally adopted very soon. Even if cemeteries are to be continued, much improvement can be gained in a sanitary point of view if the earth-to-earth system of burial is adopted. According to this system the dead are buried in wicker coverings instead of wooden or metal

coffins, so that the body itself is sooner brought in contact with the earth and thus more quickly rendered innocuous. He considered it to be as ridiculous to condemn burial *in toto* as to condemn cremation *in toto*.

In the discussion that followed the reading of this paper, Dr. Duncan, of Glasgow, dwelt with especial emphasis upon the great danger of burying those who had died of dangerous contagious diseases, such as yellow fever, and, in animals, splenic fever. He admitted, however, that there was a serious medico-legal difficulty in the way of cremation as the authorized mode of disposing of the dead, which was that in the process of cremation, arsenic, antimony, mercury, and their salts all disappeared. If antimony or lead was combined with copper, it withstood the fire. As Dr. Roche subsequently remarked, the vegetable poisons would be so much the more likely to be destroyed, and thus cremation would remove all possible chance of detecting homicide by poison.

We may conclude from this that at present there are insuperable objections to cremation, but that it is proper to familiarize people with its advantages; and above all, that it is the duty of physicians to discountenance burial in vaults and caskets such as preserve bodies for a long time in a state of putrefaction.

—A paper upon the hygiene of water will be found in Harper's Magazine for October. Dr. Titus Munson Coan, whose special studies in connection with balneology rank him as an authority, writes of "The Curative Uses of Water" in all its medicinal forms. It is peculiarly refreshing to read from a physician that "of all curative agencies water is the readiest, and not the least effective," and that thermal waters as baths are "among the most valuable cures which the physician has at hand; they represent, indeed, with the adjunct influences of climate, exercise, etc., the highest potency of the curative uses of water." The tardy appreciation of these baths, especially for nerve diseases, has permitted Europe to greatly surpass this country in facilities for the water-cure resorts, although we have unequalled natural appurtenances for their use. The workings of these baths are explained and counsel given as to the best way of using hot, temperate, and cold baths, and thermal springs.

NOTES AND COMMENTS.

Congenital Dislocation of the Hip.

Dr. J. T. Freeland, New York, writes as follows in the *Indiana Med. Journal*, September, 1887:

This is quite a rare deformity, for in a dispensary practice where new cases of articular osteitis of the hip are seen daily, an average of about one case of congenital dislocation of the hip is seen per month. The deformity is so marked and so characteristic that after seeing one case a physician can make a correct diagnosis without hesitation.

The following cases have come under my notice recently:

Elizabeth W——, aged thirteen years, was brought to the dispensary by her mother on March 5th of this year. The girl was well nourished, large for her age, and gave an excellent family history. The mother brought a letter from her family physician, which stated that the child needed a spinal brace, but no diagnosis was given. On examination there was found a very marked lumbar lordosis. The hips were dislocated upward and backward, the lordosis being merely compensatory to preserve the equilibrium by throwing the trunk further forward. She walked with a very ludicrous waddle, as the hips yielded at each step. She complained of no trouble, except that her hips quickly became tired on walking.

A line drawn from the anterior superior spinous process of the ilium to the tuberosity of the ischium (Nélaton's line) showed the heads of the femurs to be one inch above their normal positions. The feet were in natural position, and movement at the hips was normal.

The majority of these cases present a dislocation of both hips, and in these the deformity is not so marked as when only one hip is affected. When the deformity is bilateral the only peculiarities are the lordosis and the waddling gait, but when the dislocation is unilateral there is a marked limp, owing to the shortening and yielding on the affected side, and before the patient reaches adolescence lateral curvature of the spine is generally added to the existing deformity.

April 15th, 1887, Jesse Stevens, aged twenty-two months, was brought to the dispensary by his mother. The child had a

good family history, and was well nourished. From the time he had commenced walking it was noticed that he limped, favoring the left leg. Motion at the hip was unresisted. There was three-fourths of an inch atrophy of the thigh, but the circumference of the calf was the same as its fellow.

Measuring from the anterior superior spinous process of the ilium to the outer malleolus, there was three-fourths of an inch shortening; but measuring from the head of the femur to the malleolus the leg was as long as its fellow. The head of the femur was nearly an inch above Nélaton's line. The nutrition of these dislocated limbs is interfered with in some way; this is readily appreciated by comparing the limbs when but one is dislocated. The bony development, as well as the muscular, is retarded, as there is quite a difference in the real length of the legs in an adult with unilateral hip dislocation of congenital variety.

Most cases of congenital dislocation of the hip are brought to the notice of the physician when the patient begins to walk, and the parents generally consider the trouble of recent origin, and will ascribe as a cause some slight accident the child met with shortly before the visit. No physician would be likely to make the mistake of confounding the congenital dislocation of the hip with a dislocation produced after birth by trauma. The absence of active symptoms in the former, and the freedom of movement and position of the leg and foot, would make him decide at once.

The head of the femur may be dislocated before birth in one of three directions, says Carnochan—upward and backward, upward and forward, and directly upward.

The first form is the most common, and the only one worth studying practically, for the second and third forms are found only in monstrosities.

Hippocrates wrote, "children yet contained in the organ of gestation may have the arms or the inferior limbs dislocated by blows, falls, or by pressure exerted on the abdominal walls of the mother."

Paré thought that the powerful contractions of the uterus, acting on the extremities of the levers presented by the femurs while the thighs were flexed on the abdomen, were sufficient to account for this variety of dislocation.

Other authorities suppose the cause to be the arrest of the development of the cotyloid cavity. Dr. Knight, in his *Orthopedia*, inclines to this belief.

Carnochan, who has written a valuable monograph on this deformity, thinks that this dislocation is due to muscular spasmodic retraction due to a perverted condition of the excito-motor apparatus.

Hamilton, in his work on Fractures and Dislocations, expresses the belief that any one of the causes mentioned above may produce the luxation.

Post mortem examinations of adult cases show that a new joint is formed between the cotyloid cavity and the crest of the ilium; bone is thrown out until a cup-like depression is formed, and a new capsular ligament is produced. These results do not invariably follow. Occasionally the original capsular ligament becomes much elongated and remains intact, and a new joint is not formed. When a new joint is formed the acetabulum loses its shape, or becomes filled with osseous deposit, and is almost obliterated. Great changes always take place in the head and neck of the femur.

When the old capsule remains unbroken, the head of the femur can be drawn down by traction to its normal position.

Guérin, of Paris, and Parnez, of Lyons, have produced cures of this deformity in children, by overcoming the muscular resistance by long-continued traction and binding the head of the femur to its place by a band passed above the head of the femur and under the perineum; but treatment is generally unsatisfactory in results and difficult in process, and as the deformity does not interfere greatly with locomotion, it is not advisable to resort to treatment.

Chronic Laryngitis and its Sequelæ.

Dr. Hunter Mackenzie publishes a lecture on chronic laryngitis and its sequelæ. Simple chronic laryngitis and thickening of the laryngeal structures may occur as a consequence of acute laryngitis, or from repeated attacks of the subacute variety; occasionally its mode of development is protracted and insidious. It may be partial—that is, only one-half of the larynx may be thickened permanently—it may be general, affecting more or less all the intrinsic structures. The question of degree or locality of the inflammation bears an important relation to prognosis. Chronic laryngitis may be primary or consecutive. Primary chronic laryngitis indicates that the laryngeal affection has not been preceded by any local or general affection; the term consecutive may be applied

to that variety which precedes or supervenes during or after the course of the zymotic diseases, malignant disease, or pulmonary phthisis, or which is the result of extension from the nares or pharynx. In simple chronic laryngitis there is very seldom any true ulceration or loss of substance, unless there is evidence of struma, tuberculosis, or syphilis. The character of the voice almost entirely depends upon the vocal cords. Complete aphonia (whispering voice) is, in the absence of nervous or mental causes, indicative of severe laryngeal changes, and shows destruction of the vocal cords, or of the cords and ventricular bands; it is a point to be remembered that a fairly effective voice can be produced by the ventricular bands, should the vocal cords be destroyed. Chronic laryngitis, in addition to the symptoms produced on the voice, respiration, cough, etc., may sometimes be the cause of gastric disorders; when pharyngitis is present, and the saliva is in excess, or when frequent movements of swallowing are made, owing to the sense of tickling at the back of the throat, an excessive amount of air is swallowed, giving rise to gastric flatulence. The following are some of the sequelæ of chronic laryngitis. In the insidious form, the possibility of tubercular degeneration is always present; in those cases it is only by the examination of the sputum or laryngeal secretion, and the presence of the bacilli of tubercle being detected, that one can be certain the case is one of tubercular disease. Another sequela of chronic laryngitis is the formation of new-growths; these may be papillomatous, mucous, fibrous, or cartilaginous, according to their seat of origin. The more chronic a case is, the more likely is the supervision of the most serious of all sequelæ, the tubercular degeneration. In the case of malignant disease of the larynx no definite conclusion should be arrived at without examining microscopically the sputum or pieces of the growth, as in its early stages, and even in its later stages, malignant disease possesses no distinguishing characters to the naked eye. With regard to the treatment, it must be essentially of a local character to be of any use, by means of inhalations, sprays, powders or pigments. In well-marked cases recourse should be had at once to pigments, and of these nitrate of silver is the best. Commencing with a solution of thirty grains to the ounce, the strength should be gradually increased every ten to fourteen minutes, until one hundred and twenty grains to the ounce or even more are used. These pigments ought to be applied locally by means of a

laryngeal brush, under the guidance of the laryngoscope, at first three times and afterward twice a week, over a period of several months; this energetic treatment is necessary only in well-marked cases of thickened vocal cords, or of the intra-laryngeal mucous membrane. In chronic laryngitis dependent upon chronic nasal catarrh, attention should be directed to the nose; the nasal passages ought to be frequently cleansed by means of a solvent spray (one drachm of bicarbonate of soda to a pint of water), and immediately after an astringent solution ought to be applied, such as sulphate of zinc or acetate of lead, one or two grains to the ounce of water. At the same time the pharynx should be occasionally stimulated by the application of a solution of chloride of zinc, twenty or thirty grains to the ounce. In granular pharyngitis the application of London paste, or of the galvano-cautery, to the prominent follicles is usually necessary. When chronic laryngitis has ended in the formation of distinct growths, they must be removed by intra- or extra-laryngeal surgical measures. Certain of the sequelæ of chronic laryngitis may necessitate the opening of the windpipe, and the operation of tracheotomy is to be preferred to thyrotomy, if the same objects can be obtained by it. The rest and freedom from irritation that is obtained after tracheotomy often cure a chronic laryngitis which may have become serious, and in cases of tubercular disease much comfort can often be given to the patient by the early performance of this operation. The author concludes his lecture by urging on all medical men the importance of treating cases of chronic laryngitis with promptness in the early stages, so many cases being neglected at first, when some active measures might be taken, which become useless if deferred.—*The Medical Record*, August 20, 1887.

Cocaine and Strictures of the Urethra.

Van Hoorn has been successful in two cases in which he used hydrochlorate of cocaine to facilitate the temporary dilatation of strictures of the urethra. At the time of doing it he was not aware that any one had done so before. Van Hoorn then enters into the literature of the use of cocaine in this and allied affections (injection of cocaine into bladder to facilitate the operation of lithotripsy).

Van Hoorn then relates his cases and experiments. A patient who suffered from a

stricture in the posterior part of the canal was so sensitive that the application of an elastic bougie not only produced great pain, but caused disagreeable symptoms for several days after. The treatment, therefore, had to be interrupted several times, yet gradually a catheter of No. 23 (Charrière's scale) could finally be employed. Van Hoorn commenced with No. 16. Some time afterwards it was necessary to sound the urethra with an exploratory sound. This was so painful that the delay again became necessary, and he therefore resolved to use cocaine; but before he did so, he ascertained the effect of cocaine on the healthy mucous membrane of the urethra. For this purpose Van Hoorn first introduced into a perfectly healthy urethra a bougie of No. 22, with the most minute precautions. It was evident that the mucous membrane was very sensitive. The pretty large but well oiled bougie caused pain in the whole length of the canal.

Two days afterwards Van Hoorn injected, with Guyon's instillateur (before introducing the bougie), twenty drops of a five per cent. solution of cocaine. After taking out the instrument he kept the solution in the canal for ten minutes. He then introduced the same catheter which had previously caused so much pain, and the patient felt only very slight discomfort from the dilatation of the canal. To be sure that this effect was due to the cocaine, he injected the next day only water, and then passed the instrument, and found that as much pain was caused as the first time. He then used cocaine for his patient with eminent success, and although the stricture was very tight, a No. 21 catheter could be passed with but trifling discomfort. The patient had no pain the day after, and the dilatation could be proceeded with for two days.

The second case was that of a patient who had been treated a long time in another town, the doctor there telling him that he had three strictures. Introduction of the catheter was very difficult, in consequence of the existence of a valve; there was no false passage however. Introduction of the catheter was frequently followed by hemorrhages, and by so much pain that the patient one day lost consciousness. He could not bear the catheter for more than ten minutes once a week. Soon after his change of abode he acquired a fresh gonorrhœa, and consulted Van Hoorn. This complaint was pretty quickly cured, but a slight gleet very naturally remained. Eight weeks after the commencement of the last illness Van Hoorn examined the strictures, previously having

anæsthetised the urethra with cocaine. At the first session the cocaine solution had not penetrated further than past the first stricture, and the bougie, therefore, caused pain at the second one. But after overcoming these difficulties, and successfully applying the solution to the whole canal, the treatment became nearly painless, and could be proceeded with satisfactorily.—*The Med. Chron.*, August, 1887.

Removal of Necrosed Bone by Irrigations with Weak Hydrochloric Acid.

Dr. Edmund Andrews, Professor of Clinical Surgery in Chicago Medical College, gives the following account of this process in the *Kansas City Medical Record*, September, 1887:

In almost all cases of necrosis the dead bone can be removed without operation by the simple process of daily irrigation with diluted hydrochloric acid. This is especially important in spinal necrosis and caries; but is also applicable to necrosis in other parts of the body.

Nearly all our authors are silent on this subject, for though Dupuytren and other older surgeons have spoken of brushing the cavity with strong sulphuric acid, they contemplated merely a caustic action to change the condition of the diseased living parts, and not the dissolving out of the sequestrum. Others, however, have proposed the solvent plan, but without gaining a serious hearing in surgical literature. Billroth, of Vienna, briefly alludes to the subject, but scouts the whole idea in the following strong, but ill considered language: "Chemical solution of the sequestrum is not to be thought of. If you were daily to pour muriatic acid into the fistulous opening, it would affect the newly formed osseous tissue as much or more than it would the sequestrum, which would be very unfortunate, as it must replace the latter. Hence, the mechanical removal of the sequestrum is the only thing left."

In opposition to this high authority, I wish to state as the result of actual experiments that, by a little ingenuity in the management of the irrigation, most sequestra can be dissolved out; and if the solution be properly prepared it does not affect the living bone, nor act upon the soft parts, except as a good antiseptic; neither does it cause any pain. In fact, by the addition of cocaine and morphine, it can be made anodyne.

So far as my investigations have yet gone, I find no solvent equal to a weak solution of hydrochloric acid. Sulphuric acid seems to

limit its own action by precipitating the insoluble calcium sulphate in the Haversian canals, and blocking the further access of the acid. Thin laminae of bone will lie in a dilution of this acid for days with only a slight degree of decalcification. Chromic acid is also inefficient, and stains the linen on which it happens to drip. Nitric acid decalcifies the bone rapidly, but I have not yet finished the experiments for ascertaining its practical usefulness.

The proper strength of the hydrochloric solution will usually be found between one-fourth and one-sixteenth of the strength of the officinal *acidum hydrochloricum dilutum*, although it can be employed somewhat stronger by the addition of cocaine and morphine. The tolerance seems to be determined largely by the presence or absence of a good coat of granulations upon the living tissues. Directly after an operation, the cut extremities of the nerves are painful on the application of any acid, however weak; but after a few days, when covered by granulations, they bear comparatively strong solutions without difficulty.

The length of time required will vary with the strength of the solution, and the constancy of the irrigation. As the result of experiments made outside the body it was found that old sequestra, which have laid long in putrid suppurating cavities, are not deprived of their gelatiniferous animal basis. In every instance the decalcified animal matter remained in full form, but lying inclosed in granulations inside the body, it is rapidly absorbed, exactly like the decalcified bone drainage-tubes when left in position.

The method of effecting the irrigation is important. If one simply pours a little acid into the fistula, as Billroth evidently understood the plan to be, he will accomplish nothing. It is necessary to irrigate the whole sequestrum either frequently or continuously. If possible, one should have two openings, so situated that the fluid may run into one, and thence along the whole length of the sequestrum and out at the other. When necessary, new openings must be made in suitable positions, and left pervious by drainage-tubes. The next step is to fill a half-gallon fountain syringe with the acid solution, and, hanging it by the bedside, to let it run very slowly through the diseased channel. If a "through and through" irrigation is not possible, we can often obtain the same result by taking a small flexible catheter, especially of the kind having a curve near the tip, and called by the French *sonde coudée*. By a little careful management this

can often be carried to the farthest corner of the cavity, and by attaching it to the fountain syringe it will deliver the fluid beyond the sequestrum, and make it flow over it on its return outside the catheter. Whenever the sequestrum can be thoroughly irrigated, its decalcification is a matter of absolute certainty within a moderate number of days. The hydrochloric solution is a perfect antiseptic of itself, and during its use no other is required.

After the solution is completed there remains the gelatiniferous animal matter of the bone, which is identical with the material of decalcified bone drainage-tubes, and like them is rapidly absorbed in antisepticized cavities. I have commenced to investigate the possibility of dissolving it out at once with pepsin, but have not finished that part of the subject.

Billroth raises the objection that the acid will dissolve the living bone as rapidly as the dead, or even more so. So plain a point as this of course cannot fail to rise in every one's mind, but I am sure that this great man spoke from mere theory, and not from observation or experience. Whatever one might fear in this respect, I find as a matter of experience that the weak solutions which I have used do not decalcify living bone. Apparently the granulations covering the living osseous tissue protect it from contact with the acid, except in spots denuded by ulceration; and even there the circulation of alkaline blood in the Haversian canals, and the constant exudation of alkaline serum from all raw living surfaces, bone included, protect it from the action of such weak acid dilutions as I have hitherto used. At any rate, it is a positive fact that the sequestra are dissolved, and the cavity heals, without any perceptible injury to the living bone.

The Prophylaxis of Syphilis and the Regulation of Prostitution at Honolulu, Hawaiian Islands.

Dr. McGrew writes from Paris as follows on this subject to the *American Lancet*, September, 1887:

The prophylaxis of syphilis and the regulation of prostitution is a question which is at present occupying the minds of the medical profession and municipal authorities of Paris, France, and a most complete and interesting report on this subject has been prepared and placed before the Academy of Medicine by Prof. Fournier, who is acknowledged one of the best authorities on syphilis and skin diseases.

This report appears in *Le Progrès Médical*,

and the reading of it has induced me to give a few outlines of how this question has been met at Honolulu, Hawaiian Islands, where, as is generally known, syphilis raged to a great extent in former years, but where now it has become comparatively rare, thanks to the endeavors of the medical profession and government authorities (and I may here mention the name of Dr. Robert McKibben, Surgeon-in-chief to the Queen's Hospital, who has exerted himself especially in this direction) in establishing the necessary sanitary precautions.

The system there, which has been in vogue several years, coincides, so far as I am able to judge, exactly with what Dr. Fournier considers should be carried out in the city of Paris, and consists of the following regulations:

Each prostitute is forced to register her name, age, and address.

To report for examination weekly, at the government dispensary, especially set apart for this purpose, and connected with the Queen's Hospital.

If on examination she is found to be suffering from syphilis, gonorrhœa, or in fact any uterine or vaginal disease, she is compelled to enter the hospital, where there is a special ward for these cases, and to remain there under treatment until she is cured, or considered free from all danger of communicating disease.

If she leaves the hospital without permission or a certificate of health—a frequent occurrence notwithstanding the strict surveillance—she is at once searched for by the police employed for this special service, and is brought back to the hospital.

In the case of a second attempt to escape, she is sent to prison and there kept for a certain period, at the expiration of which she is glad to return to the more comfortable quarters of the hospital, and to submit to treatment.

I may here mention that during her sojourn in prison, the treatment is vigorously carried out by the prison physician, who receives, previous to her admittance, a history of her case and of her previous treatment.

This in a few words is the system employed at Honolulu, and has no doubt been the means of reducing to a wonderful extent the percentage of syphilis and venereal diseases.

Cocaine in the First Stage of Labor.

Dr. W. A. Briggs writes as follows to the *Sacramento Medical Times*, September, 1887: The "nagging" pains of cervical

dilatation, especially in primiparæ, are extremely trying, not only to the patient herself, but, indirectly, by unnecessary demands on his time and patience, to the physician also. At this time the local use of cocaine, in combination with morphine, renders admirable service. I prefer the following formula :

R Cocainæ mur. gr. 15
Morphinæ sulph. gr. 1
M. Et in suppos. (gel.) No. iii d.

Sig.—Slightly soften in warm water and introduce within the cervix uteri; repeat in three hours if necessary.

The dry powder in gelatine capsule is more easily and rapidly dissolved and absorbed, and hence is preferable to combination with cacao butter, either in mass or in shell. Relief is felt within fifteen minutes, and continues for several hours.

Non-Homœopathic Cures.

Dr. J. W. Hawkes, Professor of Materia Medica in the Hahnemann Medical College, Chicago, writes to the *N. Y. Med. Times* (a journal that detests the name homœopathy, though a staunch supporter of the doctrines of Hahnemann, as an adjunct to therapeutics), for information regarding cures obtained by measures that are non-homœopathic.

In reply, the *Times* proceeds to say, that, strictly speaking, drugs do not cure disease, but only have power to assist nature to this end; and then answers Dr. Hawkes's inquiry by giving a number of illustrations, from which we select as fair samples the three following:

Catharsis in Catarrhal Gastritis.—The curative action of cathartic medicine in certain gastro-enteric complications, accompanied with abdominal obstruction, is well known to all medical practitioners—except it may be the close adherents of homœopathy. The case we are about to relate, illustrative of non-homœopathic cures, is noteworthy by reason of the great age of the patient (86 years) and also because a council of Old School physicians had pronounced the case hopeless. The old gentleman had been "kept up" for several weeks on brandy, quinine, iron, strychnia, etc., until the bowels became obstinately obstructed and refused to respond to enemata. He was in this condition when the friends of the patient con-

cluded to consult a physician of the New School, and finally placed the case in our hands. The patient's bowels were so distended with fecal concretions as to make the leading indication of treatment unmistakable. The idea of seeking the *similimum* for such an obstructive condition did not occur to us. We began treatment therefore with compound cathartic pills (officinal) and continued with compound cathartic pills, daily, for a week, with amazing results. The patient's condition improved with every effect of the medicine. The following week magnesia citrate was substituted for the pills, and taken every morning for several days, always with excellent effect. The patient was put on a milk diet, made an excellent recovery, and still lives to rejoice at the fact.

Ipecacuanha and Spasmodic Croup.—A noteworthy case of spasmodic croup of most alarming severity, occurring in a child of five years, came under our observation sometime since. We sought the *similimum* in the case without success for several hours. The child seemed likely to die of asphyxia. In desperation we asked an Old School colleague to our assistance. We agreed that this case was a desperate one, and that heroic measures were called for. It was the evening of one Christmas day, which to my colleague was suggestive of complications of nuts and candy. Acting upon this idea four fluid drachms of ipecacuanha were forcibly exhibited to the child. The result was a copious emesis, which was followed with prompt and complete relief.

Diet in Disease.—The relation of food to certain abnormal states is well known: to disregard which would be fatal to the success of any method in therapeutics. There are conditions, in fact, in which diet and not medicine is the leading indication of treatment. We have repeatedly cured chronic flatulence, occurring in aged persons, with enlarged livers, by eliminating sugar from their dietary. All know the superiority of lean meat and skimmed milk over any form of medicine in diabetes; the benefit of a milk and farinaceous diet in catarrhal affections of the stomach; of cooked milk (boiled half an hour or more) in enteritis and ulceration of the mesenteric glands; of fresh vegetables in scurvy; of fruit and bread made from unbolted wheat meal in chronic constipation, etc. The *similimum* in all cases in which a faulty diet is the cause of malady is of non-effect, except that of palliation, and the cure of them must be by a method which is non-homœopathic.

Accidental Poisoning from *Cocculus Indicus*.

This unusual poison was taken by mistake for coca, the fluid extract having been used by oversight for the one intended. It occurred in Denver, Col., the sufferer being a gentleman from the South, temporarily stopping there, and by some, as yet, unexplained cause, the fluid extract of coca was asked for in a wholesale drug store in another city and that of *cocculus indicus* was supplied. The taste on swallowing caused the alarm of the patient, and looking at the label, a precaution that should have preceded the dose, he recognized the danger. He went at once to a physician who used the stomach pump, hypodermic injections of morphine, and, internally, chloral. The sufferings were intense for a while, but the prompt application of the above remedies saved the life of the patient.—*Pharmaceutical Record*, September, 1887.

Treatment of the Convulsions of Children.

Dr. Jules Simon, at a clinic in the Hospital for Sick Children, said that convulsions in children arose in the great majority of cases (eighty times out of a hundred) from digestive troubles. He included in the latter indiscretions in diet, entero colitis and constipation. A cause to which he desired to direct particular attention, because it was ordinarily overlooked, was exposure to excessive cold or to extreme heat. Convulsions arising out of digestive disturbances should be distinguished from those occurring in fevers. The latter then often constitute the initial phenomena of pyrexia. Still further, convulsions may be symptomatic of albuminuria, which may be latent, and an examination for which should never be neglected.

Apart from divers other affections, convulsions may arise in profuse and prolonged hemorrhages. A practical point in connection with the latter, is that Simon has seen the pulling of a tooth in a teething child—and if there is a loose tooth in a child with convulsions the doctor is generally asked to draw it—followed by death in the midst of convulsions preceded by hemorrhage. He has also seen convulsions occur in a child who had continuous hemorrhages from a slight abrasion of the tongue.

Convulsions are rare between the first and second month, and are most common between the fifth month and the second or third year. Their frequency depends largely upon individual and family predisposition. Frequent repetition of convulsions ought to make one fear some cerebral complication.

While the convulsions continue the child passes but very little urine, and then with tenesmus. This persists while the disease lasts, but one may rest assured that when the urine flows freely, the worst is over. This gives us an extremely important point for prognosis.

Generally convulsions come and go with great suddenness, but they may last eight days without occasioning a cerebral lesion. Prognosis is generally favorable except when the convulsions are secondary.

The first thing to do is to open the bowels. If the convulsion stops administer an emetic, but if the attacks continue, give 8 grains of chloral by the bowel, along with 15 grains of camphor and 20 drops of tincture of musk. In cases in which attacks recur at intervals of several hours, order a mustard bath, but only in cases where there is no fever. If convulsions still continue, blister the back of the neck, but only let the blister stay on three hours, and then apply a poultice; at the same time give the following draught:

R	Lime water.....	f 3 iij
	Bromide of potash.....	gr. xv-xxx
	Musk.....	gr. jss
	Cherry-laurel water.....	f 3 ss
	Syrup of codeia.....	f 3 j
	Syrup.....	q. s.

If the convulsions are of uræmic origin, Simon does not hesitate to bleed. In a child four or five years old, three or four leeches may be applied behind the ear; or cups with scarification over the region of the kidneys to withdraw three or four ounces of blood. At the same time the above internal treatment should be used. Even very anæmic children bear the loss of blood very well.

Moreover, nervous children that seem by their excitability predisposed to attacks of convulsions, should be isolated and placed upon small doses of the bromide every three or four hours. This will very much diminish their chances of having convulsions.—*L'Union Médicale du Canada*, August, 1887.

Injections of Quinine in Splenic Tumors of Malarial Origin.

Fazio having concluded upon theoretical grounds that injections of quinine were indicated in splenic tumors due to malarial causes, reports his results in two cases in which this method was tried, and claims to have obtained a decided diminution in the size of the tumors after respectively 32 and 45 injections.

His plan is to inject a solution of a strength of three or four grains to fifteen minims of distilled water, after deadening the sensibility of the part with the ether spray. The injections are carried deep into the tissues, and subsequently an ice-bag is placed over the seat of the injection.

The results claimed for this method of treatment are :

1. Reduction in the size of the tumor.
2. No febrile movement is occasioned.
3. No local pain is produced, and no evil effects follow it.
4. Sometimes partial emphysema of the cellular tissue occurs as the result of admitting air at the time of the injection ; but this slight evil is easily avoided with care.

Complete cure is possible only when no amyloid degeneration co-exists.—*Deutsche Medizinal-Zeitung*, August 25, 1887.

CORRESPONDENCE.

Further Report of a Case of Senile Gangrene.

EDS. MED. AND SURG. REPORTER :

Gentlemen:—I have changed my residence from Union City, Pa., to Meadville, Pa. CLARENCE G. HOLLISTER, M. D.

P. S.—The case of senile gangrene I recently reported (REPORTER, July 2, 1887,) is doing very well. Upon calling on him a short time ago the fibula was found to be separated and the tibia holding by a mere shred. The stump had nicely healed over, and his general health was improved. The cancer upon his face, however, is growing worse slowly. He will not allow us to interfere with the operation of nature in separating the limb, but insists upon letting it alone, and yesterday I heard that the leg had dropped off. This information was not, however, absolutely trustworthy.

C. G. H.

NEWS AND MISCELLANY.

A Hint to the Housewife.

At this season of the year, stewed apples, pears, and plums are favorite articles of diet. For breakfast or luncheon, in the dining-room or in the nursery, there are few table dishes more wholesome and more delicious than well-stewed fruit served up with cream or custard. There are many persons, however, who cannot eat it on account either of the acidity of the fruit or the excess of sugar necessary to make it palatable. Sugar does not, of course, counteract acidity ; it

only disguises it, and its use in large quantities is calculated to retard digestion. The housewife may, therefore, be grateful for the reminder that a pinch—a very small pinch—of carbonate of soda, sprinkled over the fruit previously to cooking, will save sugar, and will render the dish at once more palatable and more wholesome.—*Brit. Med. Journ.*, Sept. 3, 1887.

Needless Alarm.

The following piece of sublime misinformation has been perpetrated by a homœopathic physician of Montreal as a *bona fide* report of a case :

“Called to see Miss U——, suffering from usual periodic headache; gave *lach.* 75 m. (Fincke), and then dissolved a few No. 8 pellets of *pure sacch. album* in half a glass of water, *churning it well* with a spoon (potentizing it, I fear); dose, a teaspoonful every half hour till better. Soon after taking the *sacch. alb.*, she became ‘deadly sick and faint; thought she would die, *she was so weak*, could not lift her head; *felt as if she would sink bodily right through the bed.*’ Each dose made her so much worse that she stopped it, and was able to come down stairs. This is the first time I had such a symptom from *sacch. alb.*, but still it was too marked to pass without making a note for verification, either clinically or pathogenetically. I know I had pure sugar pellets and fresh water.”

We can't help wondering whether the Examining Board of the Province of Quebec have applied their final tests to this gentleman, and if so how he stood; also, whether he could pass the civil service examination here.—*The Medical Press* (N. Y.), Sept., 1887.

Camping on Mont Blanc.

A French scientific man, M. Vallot, has, according to all accounts, accomplished a remarkable feat. He has camped for the space of three days and three nights on the summit of Mont Blanc for the purpose of making meteorological, physical, and physiological observations after the manner of aeronauts in a balloon. His courageous efforts, despite his sufferings from cold and from rarefied air, as well as the exhaustion consequent on his climb to such lofty altitudes, have, it is averred by his countrymen, been successful as well as unprecedented. The result of his labors and researches has been communicated under sealed orders to the National Academy of Sciences.

Eloquent Words About Army Surgeons.

Putting aside the burning questions of rank, it may be well to place before our readers some of the well-founded claims which military surgeons have to the support and gratitude both of their fellow practitioners and of the country at large, so that if need arise to urge these claims, the appeal may not be wasted on ignorant or indifferent auditors.

John Bell, in a passage full of manly eloquence, says of the responsibilities of the military surgeon: "He is to act alone and unassisted in cases where decision and perfect knowledge are required; in wounds of the most desperate nature, more various than can be imagined, and to which all parts of the body are equally exposed. His duties, difficult at all times, are often to be performed amongst the hurry, confusion, and horrors of battle. Even in the seasons of the greatest difficulty, cold and heat, hunger and fatigue, vexation of mind, and all the distresses of foreign service, aggravate disease, and while they render his exertions of so much importance, teach him imperiously the necessity of an accurate and ready knowledge of his profession. It is to him that his fellow-soldiers look up at the moments of distress; his charities and his friendship are prized beyond all price. What part of education is there needful, or even ornamental, for the surgeon living at his ease in some luxurious city, which the military surgeon does not require? What qualifications of the head, or of the heart? He has no one to consult with in the moment in which the lives of numbers are determined. He has no support but the remembrance of faithful studies and his inward consciousness of knowledge, nor anything to encourage him in the many humble yet becoming duties which he has to fulfil except his own honest principles and good feeling."

In spite of all these onerous responsibilities, the pay and position of the army surgeon have undergone constant and arbitrary alterations, so that he has been fain to cry out like Jacob to his ungrateful master, "Thou hast changed my wages ten times." Yet notwithstanding this unworthy treatment, he has ever been found zealous to obey either the call of duty or the summons of honor.

Equal to his civilian brother in the number and value of his studies and qualifications, he has been required to pass, in addition, special examinations not less searching than those originally surmounted, and to undergo an extra training not less careful than

that previously undergone. There is no country in the world where British valor has conquered, or where, even in defeat, the stubborn pluck of Britons has covered the ground with their slain, that is not the resting place of the bones and of the dust of our military surgeons.

On the many battlefields of Flanders, beneath the burning sun of Spain, in the valley of Inkerman, in the well of Cawnpore, on the shame-stained hill of Majuba—there, side by side with their brethren in arms, sleeping the last sleep of the brave, lie the army surgeons of England. They marched and conquered and fell, with their comrades, alike in bravery and honor, alike in suffering and privation; to them as much as to these is owing the fame of our glory; it is only in appreciation and reward that there is a difference. Yet how much their country owes them.

It was a military surgeon (George James Guthrie) who, without a colleague, found himself, at the close of the bloody field of Albuera, in charge of over 300 wounded—and while the combatant officers (among whom he had fought with the bravest) lay down to rest, worn out with the long fight, he betook himself to his professional duties, and throughout the weary night, and all next day, devoted himself to the alleviation of the sufferings of friend and foe alike.

If it was of Guthrie that the historian writes: "The sudden retreat of Hill's *corps d'armée*, warmly pursued by the enemy from Aranjuez on the Tagus to Salamanca on the Tormes, encumbered with a large hospital of over 800 sick and wounded, which had been formed at Madrid, and with 2,000 sick on the whole on the line of march, without conveyance, rendered the position of the surgeon, as to character and reputation, perhaps even more critical than that of the General, who could at all times have turned and beaten his opponent. The commissariat stores and dépôt at Madrid was lost, but the whole of the hospital and the sick and wounded were saved through the energy and decision of the medical officers. Arrested on the bridge of Alba de Tormes, one-half of them were delivered over to proper officers, whom Mr. Guthrie had assembled to receive them, and returned to their regiments, while the remainder were sent forward to Ciudad Rodrigo, in compact and regular order, instead of being allowed to wander over the whole country."

What a glorious moment for Guthrie was that when he heard the Iron Duke, so usually sparse of compliment, declare "that his conduct was worthy of the imitation of the

whole army." How still more glorious must it have been to receive, as he did, the thanks of his recovered patients, saved at Albuera by his exertions, "in grateful recognition of his courage and coolness, promptitude and fertility of resource, as well as of his unflinching patience and energy."

It was no combatant officer, but a military surgeon (Brydon), whom Sale saw ride in through the gates of Jellallabad, on the point of dying from fatigue, exhaustion, and hunger, the survivor of Keith's army of Afghanistan. The same Brydon, who, in after years, was one of that little band of heroes whose fame shall last as long as the glory of their country, who, behind the frail walls of the Lucknow Residency, kept the rebel hordes at bay, and saved the honor of English women and of England.

Does the Duke of Cambridge, as he reads general orders about "combatant" and "non-combatant" officers, ever think of that misty autumn day when, surrounded by the surging mass of Russian foemen, he was only saved from death by gallant Surgeon Wilson, of the 11th Hussars, who, rallying a handful of men to the rescue, dashed into the gray mass of Russians, and brought the Duke safe and sound out of his danger? Has Lord Viscount Wolseley any fraternal recollection of that incident on the day of Inkermann (worth a dozen Tel-el-Kebirs), when Dr. Wolseley, of the 20th Foot, finding himself, unarmed, with but a handful of Englishmen by him, amidst the swarming host of Russians, instead of surrendering as a non-combatant ought, first breathed a prayer to God for his soul, then catching up a musket and bayonet lying at his feet, shouted out to the soldiers round him: "Fix bayonets! Charge! and keep up the hill!" and so tore his way through the dense mass opposed to him, and with half of his little band of heroes came safely out?

Do the critics of the Army Medical Department ask for the scientific achievement of its officers? Let them read the works of Guthrie, of McLeod, of Sayre, of Maclean, of Aitkin, of Parkes, of Longmore, of de Chaumont, of Porter, and of a score more belonging to its ranks? Do they require examples of the bravery of these men? Let them read the instances we have quoted, only selections from the records of our brave; but one other we will give, since we knew and loved its hero well. It was Surgeon-General Reade, who, on September 14th, 1857, charged down on 300 Sepoys with only a very few soldiers, because the enemy were annoying our wounded by their

fire, and defeated the rebels; it was he who, two days afterwards, was the first man up the breach at the storming of Delhi, and, with a sergeant, spiked a gun, and who was recommended for promotion in public despatches "for unwearied exertion and gallant conduct in the field."

Are instances of devotion and endurance wanted? What said Sir Charles Wilson, of the Medical Staff during the Soudan campaign, "For three days and three nights none of the surgeons of the Came Corps had any sleep at all, for they were engaged all the time performing operations or attending to the sick and wounded; and when they reached the Nile, one of the doctors actually fainted from pure fatigue and want of sleep, while performing an operation. No body of men," says Sir Charles, "could possibly have carried on their duties with such devotion as the doctors did during the Nile campaign."

Is such an instance of self-sacrifice and abnegation required as can scarcely be found out of sacred history? Again, we can refer to the annals of the Medical Department. Read of Dr. Landon upon Majuba Hill. Mortally wounded, with the agony of death closing in, in the midst of his own pain and weakness he heard a wounded soldier shrieking aloud in his sufferings, and creeping, forgetful of self, to where this man lay, gave him a morphine injection to relieve his distress, and, giving it, died! Sir Philip Sidney did scarce as noble an act as this, for he only deprived himself of a comfort; but Landon increased his own sufferings and spent his remaining strength by his exertions. In loneliness and weakness he remembered duty and pity. Of the like of his deed there are, indeed, few recorded in the annals of any age or country.

There is no marble monument above the place where the gallant Landon lies; but he sleeps as well in his turf-covered grave as he would in Westminster.

To these men we may apply in an especial sense the fine words of Sir James Paget: "And so in toil, yet not in weariness, they pursue their way, sowing seed of which they reckon not whether they shall reap any fruit; content, because they are in the path of duty, blest if only they see or think that they minister to the welfare of their fellow-man."—*Brit. Med. Journ.*, September 5th, 1887.

Amusing Experiences of a Druggist.

G. H. C. Klie writes as follows in the *Pharmaceutical Record*, September, 1887:

A customer's daughter, about ten years of age, was taken sick with a very severe attack of typho-malarial fever, as it is termed by some physicians. The attending physician treated the case with quinine. This was prescribed in pill form, and mostly administered in gelatine capsules. Sometimes they were prescribed with the usual excipients—gum arabic, tragacanth, with glycerin and aqua—but oftener the mass was directed to be made with aromatic sulphuric acid. Prescriptions were filled almost daily for weeks in succession. The child's life was despaired of, the parents themselves expecting it to die every day. It, however, pulled through, and slowly recovered. The mother calling at my store some time after, I asked how her daughter was getting along. In a slightly pettish and dissatisfied manner she answered, the child was getting along well enough, but she thought it was not the fault of the medicine or the doctor that she was thus. I questioned her what she meant. She said: "Well, sir, when my child had well advanced toward recovery, she one day desired to go to stool. After this was done I examined the chamber, and what do you think I saw? All the pills she had taken during her long illness were there, and it seemed to me the vessel was half full of them."

Her statement surprised me. I had hardly expected that all pills would turn up again in such a state of preservation. I asked her whether the capsules were there also. "No," she said, "the capsules were not, but the pills were all there." Her opinion was there was no use to have a doctor and give medicine diligently as she had done when the medicine was evidently wasted. I could not say anything against her reasoning. I only expressed to her my gratification that her child had recovered under such untoward circumstances.

This case plainly shows that there are some diseases, especially those of a typhoid character, in which pills, even when freshly made and in a soft state, are not acted on by the liquids of the stomach and intestines. Ready-made pills, or sugar and gelatin coated pills, in such cases, would not stand the ghost of a chance of being dissolved. I have heard physicians mention the fact that they have found pills administered to patients undissolved, or only partially dissolved, in the dejections, but I never heard of a case as bad as the one just related.

There are persons who exhibit an extraordinary amount of enterprise when they buy stamps and post letters. In the first place, they often want three 2-cent stamps for

5 cents, and change for a \$10 bill. Then they sometimes, with the odd cents with which they always seem provided, give you one or two with holes in them. When you have safely passed this stage, you are politely asked to put some mucilage on the envelope, and close it, too. Then, "Won't you have the kindness to write the address, which please look up in the directory." "Now, please put the stamp in the right corner." "Oh, yes! can you drop it in the box for me?" "Oh, and I had almost forgotten, the answer is directed in your care; please oblige me by sending it around as soon as it arrives." Oh! aint it glorious?

Romantic Love and Personal Beauty.

Dr. T. Wesley Mills, in September *Science*, writes as follows of his own opinion, after discussing Mr. Finck's view:

For myself, on this point, I hold the strongest views. My theory as to falling in love would be something to this effect: there are in normal minds the elements of an unformed ideal, which takes definite shape when the person answering to that ideal appears, provided there be no interfering causes. This ideal appertains rather to *type* of individual, i. e., there is the potential capacity to love one of many individuals of the type, and the exact individual of this type chosen may be a fortuitous matter. Good results, if not absolutely the best, follow in such cases, no matter which one of the type-class is chosen. As Carlyle said, "No man can love but once, and some not then." The choice of those of opposite tendencies, etc., results in a large proportion of cases in the highest good alike to the individuals themselves, their offspring, and the race. Man and woman in the conjugal state should be the one complimentary to the other. The education of the sexes should lead to as much differentiation as possible, in order that the total energy available for the race may be maximal. The education given by parents and the general education of the public should be such as to allow of the highest degree of free, intelligent conjugal choice. If this is accomplished the results as regards beauty will be equally good with those in other directions. I seem, Mr. Editor, to be just getting into the subject, but I fear I have already taken up too much of your space; the importance of such a question must be my excuse.

Medical Fees.

"In Cleveland, an office visit is twenty-five to fifty cents; in New Jersey one to ten

dollars. In Cleveland a visit from the family physician is one dollar, no extra charge for an hour or two detention, no charge for prescription to other members of a family. In New Jersey a visit from the family physician is from one to ten dollars, a dollar extra being charged for every hour's detention, and for each additional member of the family prescribed for. In Cleveland ordinary mid-wifery cases are from five to ten dollars; in New Jersey the same ten to thirty dollars. In Cleveland the reduction of a dislocation of the elbow or shoulder and its subsequent treatment is five to ten dollars, while in New Jersey the same is twenty-five to fifty dollars. Other service in proportion."—*Am. Lancet*, September, 1887.

The Foreign Visitors at Niagara.

The foreign delegates to the International Medical Congress were taken to Niagara Falls. They held a meeting on Monday evening, Sept. 12th, in the International Hotel; after the close of the meeting, at which brief speeches were made, expressing hearty appreciation of the attentions shown to them by their American hosts. Resolutions were adopted testifying their appreciation of the generosity of the Executive Committee to such visitors to Washington and the members of their families. One of their resolutions says: "The undertaking of the conveyance of over three hundred guests nearly one thousand miles, under the most luxurious conditions of locomotion, and their entertainment for four days, represents an extent of hospitality unsurpassed at any former Congress."

Reminiscences of an Old Physician.

They call me "the *old* doctor." Of course, my long white beard and the scant thatch on my head bear witness to the veracity of the term; and I have but to look at my stalwart grandsons to be fully assured that the adjective applies to me; nevertheless, I fancy that a piece of irony is implied in it. The go-ahead men of the present generation consider me out of date entirely—my ideas antiquated and obsolete. Well, I should not wonder if they are; for I suppose no branch of science has made such rapid and wonderful strides as that connected with the profession to which I have the honor to belong. No doubt, I am of the old school. I am resting on my oars now. The strife and struggle of life are over for me; and as I sit at my ease in my old armchair, memory takes

me back to the past. I think of my student days, and I see before me those grand men whose footsteps first beat into the track which has led to the present heights of research and of discovery. Abernethy was one of those splendid pioneers. I think I see him as he used to lecture at St. Bartholomew's; small of stature, nose *retroussé*, eyes small, dark, and restless, gleaming alternately with wit and humor, or lit up with ineffable tenderness. A face comical and satirical, if you will, but full of expression; and crowned with a raised tuft of well-powdered hair, ending in a long queue. He was among the last of the pig-tails. Then, to add to the quaintness of his *tout ensemble*, he had a knack of thrusting one hand into his breeches-pocket while he gesticulated with the other. No lecturer in London could rivet the attention of his pupils as he did, so lucid were his descriptions, so powerful his language, so dramatic his action. Abernethy was far from being the coarse man that some of the clumsy imitators of his naive brusqueries would lead one to imagine. True, he would launch his little winged darts of satire ruthlessly at the manifold affectations of self-indulgent invalids; he had small sympathy for such; and no regard for rank or wealth of themselves. But when his feelings were enlisted, when called on to witness real suffering, real distress, who so kind as he? And then, when poverty was super-added, the recording angel alone might tell of his benevolences.

Although a great admirer of Abernethy, the hero of my boyish worship was Sir Astley Cooper. The lives of these two great luminaries for long years ran parallel. With Sir Astley I came more into personal contact; and assuredly he was the first surgeon of his day and generation. He was President of the College of Surgeons when I went up for my examination for membership. I had just gone through the fiery ordeal, and was drawing my breath triumphantly, when Sir Astley, using his privilege as President, called my attention: "Describe to me, sir, the origin and distribution of the fifth pair of nerves." I quailed for an instant, taking in, as one does at such moments, the whole beauty of his magnificent physique; then gathering up my somewhat scattered senses, I answered slowly, deliberately, and I trust also clearly, for I heard him say "Capital!" No word of praise, either before or since could have the electric effect of that tri-syllable. It was positively intoxicating. My fortune seemed to be made from that moment.—*Chamber's Journal*.—*Canadian Practitioner*, September, 1887.

An Accident Service.

Dr. C. J. Clebourne, medical inspector of the United States Army, organized in Philadelphia a Volunteer Medical Service along the line of parade at the Centennial Celebration of the Adoption of the Constitution of the United States. A full number of physicians and assistants were in attendance.

An ambulance or police patrol wagon was stationed at or near each "dressing station," which was at the disposal of the medical officer in charge, upon application to the police in attendance.

In case of serious accident or injury a "first dressing" was applied, and the case at once transferred to an ambulance or patrol wagon and sent to the nearest hospital, hotel, or police station. No ambulance was permitted to go from the station to which it was assigned a further distance than five squares. The covered wagons of the Union Transfer Company, with straw in the bottoms, were used.

The Liquor License.

Every druggist in the United States pays into the national treasury annually twenty-five dollars for the privilege of selling medicines, on the pretext that many of them contain alcohol, and alcohol is at the root of one of the most deplorable of human vices. While there was a heavy national debt to be paid, or in the earlier years in presence of the enormous expenditures which left us burdened with that debt, we accepted the necessity without questioning the logic; but today, with an overflowing treasury, we can no longer submit quietly to an imposition as unjust as it is burdensome. Self-respect, indeed, forbids that we tolerate it without indignant protest. We resent it because, in assuming a relationship between the business of the pharmacist and that of the liquor seller, it grossly misrepresents facts. We resent it all the more because of its demoralizing influence, since the man who pays a license is under strong temptation to avail himself of any "privileges" it may confer.

In many States the true relations of the druggist to the saloon keeper have been defined by law. The rights of the druggists to dispense liquors as they do other medicinal agents, strictly for medicinal use, cannot be questioned, and the hardship of imposing on him the tax which is laid upon the sale of intoxicating beverages, as such, is clearly recognized. The same principle applies to the national tax, and we show little of the

spirit of our revolutionary forefathers if we tamely submit to its infringement. The question of how most wisely to array our forces to secure our rights in this matter is likely to engage the attention of the various pharmaceutical organizations in the country, and will no doubt come up for discussion at Cincinnati. At present we shall offer no suggestions of our own. It is more important that druggists throughout the country be made to feel that something must be done, and that each one can help a little. With this idea in view, we have addressed a number of prominent pharmacists a letter asking that they would give as briefly as possible their views on the matter.

Some communications we have received are presented with fullness and force, and are to be commended as subjects for careful and thoughtful study.—*Phar. Era*, September, 1887.

A Suit for Expert Services.

Dr. John J. Reese, Professor of Toxicology in the University of Pennsylvania, and Dr. Henry Leffman, of the Polyclinic, have brought suit against the city of Philadelphia to recover for services rendered in the analysis of the viscera of the bodies of three of the supposed victims of chromate of lead used to color buns. Their professional services were rendered to the Coroner of Philadelphia in connection with the recent investigation of this matter.

ITEMS.

—Keeper Maest, of the Erie County Almshouse, says that in his experience, one of the peculiar freaks of insanity is the seeming reversal of natural tendencies. "For instance," he says, "we have in the male wards fine collections of potted plants and climbing vines, which grow so luxuriantly that they curtain the windows. The men tend these carefully, pluck away the dead leaves, stir up the dirt in the pots, prune the vines, keep them carefully watered, and in divers other ways manifest the tenderest watchfulness. Not so with the women. Every attempt to introduce plants and vines as a feature of the female wards, save in the cottage where the mildest cases are confined, has proved a flat failure. The women pull out the plants by the roots, tear down the vines, and manifest other destructive tendencies entirely at variance with the nature of the sex in general."—*Phila. Press*.

OBITUARY.

DR. C. T. MELSHEIMER.

The following is sent us by Dr. H. V. Sweringen, Fort Wayne, Indiana: Dr. C. T. Melsheimer, of Bluffton, Indiana, one of the most prominent and respected practitioners in this State, and an old subscriber and contributor to the REPORTER, died at his home on August 27th, 1887. While he was a pioneer, belonging to the old class of physicians, he kept pace with the progress of the profession, was a student by nature, intent upon solving the problems which have been hitherto unexplained. A man of sound judgment and a modest gentleman withal, he enjoyed the supreme confidence of the laity and a large and lucrative practice.

DR. GEORGE BRUNDAGE.

Dr. George Brundage, of Factoryville, Pa., was accidentally shot on September 9th, 1887, by a friend who was handling a pistol which he did not know to be loaded. He died in about twenty minutes. An examination showed that the ball had entered the stomach, perforated the bowels, and taken a downward and backward course. Dr. Brundage was 36 years of age. He was one of the most prominent citizens of Factoryville, and was well known throughout the neighboring counties. He was married and leaves a wife and three children.

Resolutions.

DR. EDWARD WILLIAM GERMER.

A special meeting of the State Board of Health was held on Thursday, September 1st, 1887, at the Executive Office, No. 1532 Pine street, Philadelphia, to take action in reference to the death of late President of the Board, Dr. Edward William Germer, of Erie, when the following resolutions were adopted:

Resolved, That this Board has heard with profound regret of the decease of its valued fellow-member and late President, Dr. Edward William Germer.

Resolved, That, in a thorough and intelligent understanding of the principles of State hygiene, learned at the feet of Europe's earliest teacher in this most important branch of medical science, he had few equals; and in untiring energy, courage and self-devotion in their practical application, in times of public danger, no superior.

Resolved, That while the Board in its official capacity has lost an able, wise and faithful member, whose whole energies were devoted to the good of the people, as individuals we mourn the departure of one whose endearing social qualities and warm emotional nature made him a delightful companion and a true friend.

Resolved, That copies of these resolutions be forwarded to the daily and medical press and that a copy be sent to the bereaved family.

DR. N. ARCHER RANDOLPH.

At a special meeting of the Auxiliary Faculty of Medicine, held September 5th, 1887, in Biological Hall, University of Pennsylvania, the following resolutions were adopted:

Resolved, That this Faculty has received with the profoundest sorrow the intelligence of the sudden death of their esteemed colleague, Doctor Nathaniel Archer Randolph, late Professor of Hygiene in the University of Pennsylvania.

Resolved, That in the demise of Dr. Randolph this Faculty has been deprived of a most faithful and zealous co-worker, endeared to them by the uniform courtesy and gentleness of his deportment, and that the University has lost a Professor of great merit and of brilliant promise, and one most acceptable to the students under his charge.

Resolved, That this Faculty begs to tender to the widow and family of their late colleague the sincerest sympathy and condolence in this afflictive bereavement.

Resolved, That these resolutions be published in the medical journals of this city, and that a copy of them be forwarded to the family of our deceased colleague.

J. T. ROTHROCK, M.D.,
Philadelphia, Sept. 12, 1887. Deau.

There have been no changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from September 11, 1887, to September 17, 1887.

Changes in the Medical Corps of the Navy for the week ending Sept. 17, 1887:

P. A. Surgeon Richard Ashbridge, detached from "Constellation" and ordered to the Naval Academy, Annapolis, Md.

Surgeon Joseph G. Ayers, detached from Torpedo Station, and to await orders.

Surgeon John C. Wise, ordered to relieve Surgeon Ayers at Torpedo Station.

Medical Director Samuel T. Coues, detached from Hospital, Chelsea, Mass., and placed on retired list, Sept. 17, 1887.

Surgeon George P. Bradley, leave of absence extended six months, with permission to remain abroad.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ending Sept. 17, 1887:

W. H. H. Hutton, Surgeon, granted leave of absence for thirty days, Sept. 15, 1887.

George Purviance, Surgeon, granted leave of absence for thirty days, Sept. 13, 1887.

S. T. Armstrong, P. A. Surgeon, granted leave of absence for thirty days, Sept. 13, 1887.

A. H. Glenan, P. A. Surgeon, to proceed to Charleston, S. C., for temporary duty, Sept. 15, 1887.

J. H. White, Asst. Surgeon, granted leave of absence for twenty-seven days, Sept. 13, 1887.

Norman Seaton, Asst. Surgeon, granted leave of absence for twenty days, Sept. 16, 1887.

F. C. Heath, Asst. Surgeon, to proceed to Mobile, Ala., for temporary duty, Sept. 15, 1887.

PROCIDENTIA UTERI.

A Clinical Lecture delivered at the Jefferson Medical College Hospital, September 22, 1887,

BY AUGUST MARTIN, M. D., OF BERLIN,
GERMANY.

Professor of Obstetrics and Diseases of Women in
the University of Berlin.

Reported by William H. Morrison, M. D.

“Gentlemen:—As you well know, the procedure for the cure of procidentia of the uterus has, through improvements in the method of operation introduced during the past ten years, become one of the most successful of gynecological operations; and by it we have succeeded in doing away with the objectionable pessary, which during that time had been used in the treatment of this condition. As was first pointed out by Hegar, we cannot retain the uterus by any operation on the vaginal wall alone; such operations are only temporarily successful. After a time, the uterus again comes down. In order to successfully retain the uterus it is necessary to strengthen the floor of the pelvis. When we succeed in arranging in the floor of the pelvis a cicatrix sufficiently strong to carry the uterus and the prolapsed vagina, we may hope to keep the uterus and vagina in their proper positions. In treating a case of procidentia, we must repair any defect in the uterus and restore it to a condition as near the normal as possible; we must direct atten-

tion to the vagina and relieve any trouble that may exist there, and we must also restore the perineum. These three different forms of operation can be done at one sitting. Their performance is accompanied with very little loss of blood, and the results are such that this operation can be highly recommended to your patients.

“The patient on whom I shall demonstrate this operation has a rather large womb, which is retroflexed and with a cervix torn on the left side. I shall restore the cervix, and lift up the uterus and bring it into a position of anteversion. I shall next remove an elliptical-shaped piece of the mucous membrane from the anterior wall of the vagina. I shall then unite the edges of the wound thus left. This may be accomplished in two ways. The wound may be brought together by the interrupted silk suture; but a much better way is by the continuous catgut suture. With this the wound may be brought together in different layers, some of the sutures being buried. Beginning at the upper angle of the wound the edges are brought together with the continuous catgut suture until slight difficulty is observed in approximating the edges. Then the suture is passed through the bottom of the wound, including a certain amount of the tissue. When the suture has reached well down to the lower angle of the wound, the edges of the wound are again caught with the thread and brought into apposition. There is then left a wound one-half of the length of the original denuded surface, which is next brought together with the continuous suture. The catgut used is of such a size that it will continue in position for at least ten days.

"For the posterior wall, I perform an operation which is in correspondence with the natural condition of the parts. As you know, the vagina is formed by the union of the two Müller's canals. As a result of this we find in the lateral walls of the vagina dense lines of fibrous tissue. In all the other methods of treating prolapse of the vaginal walls, this very dense tissue is cut off and denuded. My plan is to retain this, and the posterior pyramid is also preserved, the lateral walls being brought into apposition with it, as will be seen when I come to operate. After the vagina is narrowed in this way, I shall perform an operation for the restoration of the perineum. This is quite a common operation, the cicatricial tissue being removed and the denuded surfaces being brought together with the catgut sutures."

The patient was then brought in. There was complete procidentia and the uterus presented a marked laceration on the left side. The right side of the cervix was first incised to the same depth as the laceration and then, as the cervix was decidedly hypertrophied, a wedge-shaped piece involving the whole width of the posterior lip was cut away, a strip of mucous membrane being resected at the position of the future cervical canal. Interrupted catgut sutures were then introduced, securing the strip of mucous membrane to the denuded surface. This also had the effect of checking the bleeding. A portion of the anterior lip was then removed in the same way, and after the strip of mucous membrane had been secured, the two lips of the cervix were brought together with catgut sutures.

The operation on the cervix having been completed, the uterus was drawn down exposing the prolapsed anterior wall of the vagina. This was then denuded, an elliptical portion of the mucous membrane being removed. The denuded surface was four inches in length by two inches in width at its widest part, and extended from just behind the urethra to the junction of the vagina with the cervix. Catgut sutures were then introduced, beginning at the urethral extremity of the wound, the continuous suture being carried as far as the tissues could be readily brought in apposition. This was a distance of about one inch. The suture was then buried in the bottom of the wound, bringing this together to a certain extent. It was then continued towards the lower angle of the denuded surface, until a point was reached where the edges could be brought together with ease. After the lower edges were coaptated, the suture was again carried

upwards and a portion of the surface left exposed was brought together; but the tension still being considerable, a second row of buried sutures was introduced. Finally the edges were united, and the wound in the anterior wall entirely closed.

The next step in the operation was to replace the uterus, which was done with a sound, the organ being left in a position of anteversion. The posterior column of the vagina was then brought down and a point in the left lateral wall of the vagina, which could readily be brought in apposition with the posterior column, was selected. This left a sulcus which was denuded and the raw surfaces brought together with the continuous catgut suture. The right side was then treated in the same way. By this measure the posterior wall of the vagina was narrowed.

It still remained to restore the perineum. This was done in the usual way, the cicatricial tissue being removed, the line of denudation extending up to the point where the operation on the posterior wall was performed. The first sutures were passed through the upper portion of the wound, including the parts already brought together in the operation on the posterior vaginal wall. The cutaneous surfaces were then united with the catgut suture, and finally the vaginal edges were secured with the continuous catgut suture.

In regard to the after-treatment of the case, Dr. Martin said: "The wound will be left entirely alone, and the patient kept in bed on her back for three weeks. The catheter will be used frequently and the bowels moved on the fourth day. The patient must not be allowed to exercise much before the expiration of three months, and sexual intercourse must be prohibited for at least six months."

In the operation Dr. Martin was assisted by Dr. Howard A. Kelly and Dr. William Ashton.

NOTES ON THE THERAPEUTICS OF PAPOID.

BY PIERRE WILMORET, M. D., BUENOS
AYRES, A. R.

On September 14th, 1855, M. Bouchut, then a boyish hospital physician, described to the Academy of Medicine of Paris, the operation of intubation of the larynx. Two weeks later, M. Trousseau violently attacked both views and method; and in the discussion that followed there was so much warmth that Trousseau went to the tribune, attacking Bouchut's honor, charac-

ter and ambition. The unfortunate physician came forth with his career almost ruined; and with his discovery rendered ridiculous by the biting sarcasm of the leader of French laryngologists, he could do no more than to reiterate his statements, and await the future to prove the correctness of his ideas and belief. While thus working and waiting, it was the fortune of Dr. Joseph O'Dwyer to place intubation at the fore-front, and thus to bring a mead of honor to both Frenchman and American.

Twenty-three years sufficed to give the Parisian professor agrégé, a world-wide fame, and on the occasion of the Sixth International Medical Congress at Amsterdam, it was expected and believed that he would evidence his ability, and prove that he stood on the heights of French medical science. There were those who were disappointed when he came to read his paper "On a Vegetable Substitute for Pepsin." Not strangely the disappointment waned when he narrated his experience and experiments with the alkaloid, papayotin or papoid, which he had derived from the juice of the *carica papaya*, a tree of Java. He interested all, and the interest did not flag when Professor Wurst followed with a priority claim of having isolated the same alkaloid from the *papaia* of South America. The time and place were favorable to the Parisian, inasmuch as Japanese products counted for more in Holland than did anything of American discovery. But Bouchut gracefully acknowledged the German's work, and with the consciousness of having done another notable deed in medicine, he left it for German elucidation.

It was during the Third Congress for Internal Medicine that Professor Finkler, of Bonn, appeared as elucidator. This observer put forward the claim that in papoid there was to be found a true substitute for pepsin, especially in the treatment of diphtheria in the solution of false membrane, and in the treatment of dyspepsia as a stimulant of the gastric glands, and as supplying an essential constituent of the gastric juice.

M. Bouchut at the Ninth International Medical Congress has given tribute to an American for having brought to success his contribution to the laryngology of 1855. Is it too bold a forecast to believe that at the Tenth Congress he will give an equal tribute to a German for furthering his other contribution to the laryngology of 1878? Intubation in its place is paralleled by the perfect solution of pseudo-membranes, and Finkler is of the same discipleship as O'Dwyer.

The Professor is fully conversant with the reasons that seem to require a substitute for pepsin. It is a matter for consideration as to whether papoid is calculated to render such substitution. The testimony of all who have tried substitution seems to be in the affirmative, and in view of the importance of the subject, it is instructive to collate the testimony against pepsin and in favor of papoid, which is found in the experience of trustworthy observers, both as to the digestive powers of papoid, and as to its powers as a fibrin solvent.

M. Bouchut, with his characteristic modesty, professes no longer to urge the use of the remedy for the particular purposes indicated; but is satisfied as to its value there, is enthusiastic in commending it as doing what only the best of pepsin will do, and that is the solution of cutaneous carcinomata by deposition of a solution of it in the substance of the malignant growth. Like Theirsch with pepsin, he reports success with its use.

Finkler, who has done most to promote the value of papoid, has taken several occasions to urge it as a substitute for pepsin. That he has succeeded in this is manifest by the fact that papoid is as much discussed in Germany to-day as was cocaine a few years ago. Of its use in diphtheria the *Bonn Therapeutist* says:

"When applied to the diphtheritic membrane it dissolves it in a few hours, destroying the microbe of the disease, and thus causes an early fall of temperature. It holds tenaciously to the fibrin, and, once applied, nothing can prevent the destruction of the membrane. It may be applied as a solution or as a paste. If in solution, I prefer a strength of one-fifth, with applications every half-hour in the form of spray. Better and quicker results can, however, be obtained by rubbing up gr. 5 with as much water as will make a thin paste, and applying this with a brush."

Touching its physiological action in the stomach, the observations of Finkler are as follows:

"1. Unlike pepsin, its action begun in the stomach, is continued in the intestine.

2. While pepsin will only act in presence of an acid, papoid acts with unvarying energy, be the reaction acid, alkaline, or neutral.

3. It dissolves at least 1000 times its own weight of fresh fibrin.

4. It acts as an antiseptic.

5. In contrast to pepsin, it acts when the resulting peptone solution is highly concentrated, and such action is highly energetic.

6. It is of uniform quality.

7. The conditions under which it changes albumen into peptone are different from those observed for same effect with pepsin or trypsin.

8. It is harmless and easily tolerated.

9. It acts in presence of other drugs.

10. With its use the possibility of poisoning by ptomaines is rendered negative."

"It improves digestion, stimulates the gastric glands, removes morbid membranes, mucus, and pus; and relieves pain and vomiting."

He has employed it successfully in dyspepsia, gastric and intestinal catarrh, anorexia, flatulence, alcoholic emesis, anæmia, and for relief of some of the distressing symptoms of gastric carcinoma and ulcer. The dose is grs. ij-v, during meals, and with as little liquid as possible. "Distinct cure is produced rapidly."

Dr. George Herschell says of the drug: "In it we apparently have an ideal digestive ferment, catalytic in character." This he has proved by experiments. He "finds it chiefly valuable in chronic summer catarrhs of children, 'biliousness,' non-assimilation, flatulence, acid dyspepsia, and gastralgia."

Dr. A. Jacobi, of New York, has successfully used papoid, and both before the State Medical Society and the Academy of Medicine, has read papers on its use. Agreeing with Finkler and others as to its physiological action, he bases its therapy upon three facts, viz.: (1.) It is innocuous taken internally. (2.) It is dangerous when given subcutaneously. (3.) Upon injection it paralyzes the heart and nerves.

"Diphtheritic membranes are dissolved in a few hours. It is easily dissolved in 20 parts of water, and is certainly a solvent of membrane, injected, sprayed, or applied with a brush. In greater concentration, one part to four or eight, I have applied it to the nose, throat, and trachea, through the canula, after tracheotomy, with fair results." He narrated four cases to the State Society. No. 1 was pharyngeal diphtheria; boy 11 years old; extensive membrane; hourly application of a 4 per cent. solution destroyed the membranes. No. 2 was a case of membranous laryngitis; extensive membrane; use of papoid after tracheotomy; recovery. No. 3, H. B., 15 years old; severe nasal and tonsillar diphtheria; 2 per cent. solution of papoid applied every hour; destroyed membrane in 36 hours. No. 4, J. L. O., 38 years old; diphtheria; seen in consultation after four weeks' illness; membrane persistent; papoid solution locally applied; attending physician reported, "the membrane melted down

rapidly, and within 48 hours had completely disappeared." Dr. Jacobi's conclusion is that it "is a true digestive ferment."

Dr. J. A. S. Grant (Bey) says: "Of late 'papayotin' [papoid] has been in use in Germany as a remedy for diphtheria. Its action seems to be solvent, though weak solutions do not have this effect. It is innocuous when taken internally, but when injected into the blood it paralyzes the heart and nervous system. It must not therefore be used without certain precautions, and I should be very chary in applying it to a bleeding surface. Its local application prevents the fibrinization of the serum thrown out by the blood vessels on any surface, whether on a mucous membrane or on an abraded skin; but the living healthy mucous membrane is not affected by it. About one to six is the average strength of the solution to be used, and this may be applied to the part affected, by means of a spray, or of a brush, gargling, or by drinking. Two or more of these methods may be combined if desirable, and persisted in every hour till the membrane is dissolved or obliterated. This will probably occur after eight or even fewer applications. In my opinion it digests the membrane in the same way as the gastric juice digests the fibrinous material in our food, and may or may not have a parasitocidal action."

Dr. C. E. Billington, of New York, remarks, "of lactic acid and of pepsin it is probably safe to say that, though they have now been for some years before the profession, their practical value as solvents of diphtheritic membrane has not been satisfactorily demonstrated. The digestive solvents,—trypsin and papayotin (papoid),—are at present interesting subjects for study." In directions for the use of the remedy, Dr. Billington quotes Finkler, Schoffer, and Jacobi.

Dr. F. M. Dearborne, of the U. S. Navy, has used papoid to some extent. He says: "In two cases of chronic dyspepsia where there was severe gastric pain, the patients found immediate and continuous relief from three-grain doses, after ordinary pepsine had failed to relieve them."

A writer in *The Medical Annals*, vol. viii., No. 7, says: "Papoid is almost as important a discovery in the line of digestive ferments as quinine was in antipyretics. It is a new and important remedy, superior in every respect to animal pepsine, and free from the danger of blood-poisoning, being entirely vegetable in its action, and not prepared like other ferments from the stomachs of pigs

and other animals, with always a possible doubt as to the healthy condition of the material. Its advantages over pepsine are such as to command the attention and interest of our physicians to the same extent in this country that it has in Europe."

Dr. Willard H. Morse, of New York, who has made more extensive researches into the value of the newer remedies than any other American, says: "Papoid promises more than almost any other new therapeutic agent. It certainly fulfils all of the indications for the treatment of dyspepsia, and comes nearest of all remedies as a *specific* solvent of pseudo-membranes in diphtheria."

Prof. Anstie says: "I am opposed on principle to new remedies, firmly believing that it would be better to revive the use of some of those which are old and well nigh obsolete. Yet I admit that there are drugs that 'must go,' and one of such is pepsina porci, which should be tabooed, if for no other reason, because of the possibility that it is derived from trichinous material. The vegetable pepsine, papoid, accomplishes all that we have hoped for from the animal product, and I look for the latter's dispossession by it."

On the whole there is a great weight of testimony in favor of papoid, and so far as the writer's observation goes there is not current any dissenting opinion regarding its value. We admit the necessity of a substitute for pepsine, and we may ask if such a substitute is not to be had in papoid; is there any other than the affirmative answer, or any hesitation in pronouncing it?

TREATMENT OF ABORTION.

BY E. C. HELM, CHICAGO, ILL.

It might seem that nothing new could be written upon this trite subject, and indeed, what I have to write is not at all new. But, old though it be, it is not brought as forcibly to the notice of the younger members of the profession as it should be.

In abortion, during the earlier months of pregnancy, it is often exceedingly difficult to remove the placenta. Of late some writers have taught that a retained placenta is not as dangerous as had been supposed. Be that as it may none will deny that it is better to secure its removal, if that can be readily and safely brought about. Among the many aids to expelling the contents of the uterus, when such a proceeding becomes necessary, are mentioned tampons and ergot, but the details and intimate connection of these two

means are not sufficiently dealt with. They are often spoken of incidentally in connection with dilatation, curette, placental forceps, finger, etc., while in fact these latter measures need *very rarely* be resorted to if tampons and ergot are properly used. Besides the ease with which the latter means are used, it does not mangle the placenta, thus leaving shreds behind, but expels it entire.

I had frequently used tampons and ergot, but not as hereafter described, and had little success, when about two years ago meeting Dr. Ed. Bert, of Chicago, in consultation at a case of miscarriage, he suggested that I use ergot and the vaginal tampon conjointly, saying that it would more than meet my most sanguine expectations, and that usually the placenta would be in the vagina within twelve hours. Since that date I have used it in about a score of cases, all under five months, without a single failure. At first I used Squibb's fl. ext. ergot; but as that frequently caused nausea and vomiting, I substituted ergotine, which acted as efficiently and produced no bad effects.

As soon as abortion is deemed inevitable, I remove all clots from the vagina, and then tampon firmly with pledgets of cotton. To facilitate removal I have these pledgets, six to ten in number, fastened to a long string after the manner of a kite's tail. The tampons are thoroughly oiled, or wrung out in soap suds and covered with soap, and introduced well up to and around the cervix. As many as possible are crowded in until the vagina is well distended and a sense of fullness, not amounting to pain, is produced.

This very tension and consequent traction on the cervix tends to dilate the os. Hemorrhage is now checked, and enforcing the recumbent position, I prescribe a three grain ergotine pill every two hours and take my leave, feeling sure that within twelve hours the placenta will be expelled.

To illustrate, I will give a brief description of a few cases:

1. Mrs. N., aged 25, had severe pain and considerable flooding for several hours. I found the os rigid, but dilated so as to admit the point of my index finger. I tamponed and gave five three grain ergotine pills, one every two hours; when the tampons were removed the fœtus and placenta were found lying in the vagina.

2. The next day Mrs. J., aged 30 years, called me. She had had pain a few days before and had been flowing for three weeks, for the last twenty-four hours excessively, but her pains had ceased. The os was rather soft and nearly as large as a dime. I tamponed

for six hours, but failed to stop the flow entirely. There was still no pain, so I gave ergotine as in the previous case. After the second pill expulsive pains set in, and in five hours I was recalled with the statement that the pains were violent. Within ten minutes I was there and found the woman at rest, with tampons, and the foetus and placenta in unruptured membranes lying in the bed.

3. Mrs. B. had been flowing at intervals for four weeks. I had attended her in a previous abortion and had, after infinite trouble, dilated the os and removed the placenta with my finger. This time the os was dilated to $\frac{1}{2}$ inch in diameter. I tamponed and gave ergot at night. The next morning upon removing the tampon I found the foetus and placenta entire in unruptured membranes, lying in the vagina. Her pains, which were never violent, had ceased about midnight, when, doubtless, the ovum had escaped into the vagina.

4. Recently I was called to see Mrs. L. A midwife had treated her and had removed a ten week's ovum, but the placenta remained behind. I tried to reach it with my fingers but failed. So I resorted to the tampon and ergotine, as in previous cases. In eight hours I returned and removed the tampons, and as I anticipated found the placenta lying in the vagina.

Many similar cases might be cited, but they would be scarcely more than repetitions. In one case I had to tampon again and continue the ergotine another twelve hours. After removing the tampons I ordered a hot-water injection, tonics, and rest for a few days.

The foregoing is offered very diffidently, lest I have written what every one knows and practices; but as this treatment, in this form, has proved of such service to me, I hope it will to others. If any one has not tried it, I bespeak for it a fair trial, and feel sure it will be found all that could be desired.

RODENT ULCER CURED WITH LACTIC ACID.

BY CLARENCE HOLLISTER, M. D., MEADVILLE,
PENNA.

A case has recently occurred in my practice which I think of sufficient importance to occupy a little space in the *REPORTER*.

Mr. H., a well-to-do gentleman farmer, consulted me about a hard warty growth, about as large as a pea, upon his left cheek, being anxious to know whether or not it was

a-cancer. After carefully examining it, I was in some doubt as to this point; but, as the patient was so anxious, I advised its removal on general principles. To this he objected, and left me for about a month. At the end of this time he returned, and I found the growth changed for the worse; it was twice as large as before, red, irritable and hard. The surface was partly covered by a hard scab, appearing, as Erichsen says, as if the ulcerated sore had become too large for the scab. He informed me that during the last week he had consulted two physicians in a neighboring city, who pronounced the growth to be malignant. I now expressed the opinion that the disease was lupoid, or rodent ulcer. I explained its nature and again advised its early removal. He agreed to this, and a day was set for the operation. When the day came he asked me to try for two weeks the local application of lactic acid, as suggested to him by a gentleman, who said that his wife had been cured of a similar condition by the application of the above acid. I saw no harm in waiting two weeks and agreed. He made the application every other day for two weeks, using nothing but ordinary lactic acid. After the first day or two the ulcer appeared red and more irritable. Indeed I feared he would be obliged to discontinue its application, the scab having come entirely off twenty-four hours after the first application. He however concluded to continue the whole two weeks, which he did, making an application every alternate day; and when he came back at the end of the second week the whole of the ulcerated tumor had disappeared, and the surface upon which it had rested was smooth and almost entirely healed over. One week from that date his left cheek presented no evidence of disease except a slight redness, the skin covering being not fully developed. I was satisfied that I had a case of lupoid or rodent ulcer before the lactic acid was thought of, and had decided to remove it entirely at once; but under the application above described the disease melted away and vanished without other treatment of any kind.

That I was correct in my diagnosis was corroborated by the other medical men consulted, and by the care used in making my own diagnosis. Indeed the growth seemed to be described definitely and typically by the article in Erichsen's *Surgery*, the characteristics of the growth tallying exactly with his description. The results of the use of lactic acid were so entirely unexpected and so very satisfactory I felt it might be well to communicate it to others.

SOCIETY REPORTS.

NINTH INTERNATIONAL MEDICAL CONGRESS.—WASHINGTON, 1887.

WEDNESDAY, SEPTEMBER 7, (*continued.*)**Section on Pathology.**

The first paper presented was entitled "The Pigmentation of the Skin at the Articulation of the Phalanges in Chlorosis," by Dr. Pouget, of Cannes, France. The author called attention to the pigmentation of the knuckles in chlorosis, a peculiarity first noticed by Bouchard, of France.

Dr. Thos. Taylor, of Washington, D. C., followed with a paper on "Chrystallography of Fats," in which he discussed the hygienic relations of fats.

Dr. Kartulis, of Alexandria, presented a paper on "The Etiology of Liver Abscess," which was read in the author's absence by Dr. J. S. Grant (Bey), of Cairo, Egypt.

The last paper was read by Dr. Chas. W. Earle, of Chicago, whose subject was "Fibroid Degeneration of the Pancreas," of which disease he had previously reported cases. There was danger of mistaking the disease for cancer.

At the afternoon session, Dr. Jno. North, of Keokuk, Iowa read the opening paper on "The Pathological Relations of Ptomaines and Leucomaines."

Dr. Victor Vaughan, of the University of Michigan, followed with a paper on "Tyrotoxon."

Section on Public and International Hygiene.

Dr. B. W. Richardson, of London, England, sent a paper on "The Growth of Preventive Medicine in Great Britain."

Dr. Domingos Freire, of Rio de Janeiro, Brazil, read an interesting paper on "Vaccination for Yellow Fever," in which he endeavored to show that the disease could be prevented by inoculation with attenuated virus. He claims good results from this method, even to the stoppage of contagion.

Section on Military and Naval Surgery.

Dr. Moore, of Richmond, Va., read a paper on "The Treatment of Penetrating Gunshot Wounds of the Abdomen."

THURSDAY, SEPTEMBER 8.

At the General Meeting resolutions were unanimously adopted favoring the proposed celebration at Washington, in 1892, of the 400th Anniversary of the Discovery of America by Columbus. A resolution was

proposed by Dr. Gihon, and adopted by the Congress, that a committee be appointed composed of a representative of each nationality represented at the Congress, which committee should select the next meeting place of the Congress. This committee subsequently reported that Berlin had been chosen as the place of meeting of the Tenth International Medical Congress.

Dr. P. G. Unna, of Hamburg, Germany, then delivered an address upon "The Relations of Dermatology to General Medicine," in which he strove to point out the interest that every general practitioner should feel in the deeper study of dermatology. Dr. Unna then proceeded to point out the real difficulties encountered in the study of dermatology. Progress in knowledge of skin diseases is progress in knowledge of general pathology and therapeutics. It would be better to conduct pathological and therapeutical experiments upon human skin than upon the lower animals. The author also recommended the establishment of a central institute where able men could work together. Such an institute he hoped the United States would be the first to found.

Section on Pathology.

The following papers were read: "Removal of the Superior Maxilla," by Dr. Leopold Servais, Antwerp, Belgium; "The Natural Agencies Exhibiting the Life Processes of Pathological Organisms," by Dr. Jackson, Norfolk, Va.; "The Pathological Anatomy of Alcohol," by H. F. Formad, Philadelphia; "Cellular Digestion and its Utility in Pathological Processes," by N. S. Davis, Jr., Chicago.

Section on Public and International Hygiene.

A paper (translated) by Dr. Tomassi Crudeli, of Rome, Italy, on "Facts and Theories Relating to the Cause, Nature and Prevention of Malarial Fever," was read.

This was followed by a paper on "The Influence of Climate on the Production of Cholera Infantum," by Dr. Geo. T. Maxwell, of Ocala, Florida. The author expressed the belief that heat was not an essential element in the causation of the disease.

Dr. A. N. Bell, of New York, read a paper on "The History and Practical Application of Steam as a Disinfectant."

The following papers were also read: "The Sanitary Inspection of Railroad and Passenger Cars," by Dr. Harvey Reid, Mansfield, Ohio; "Public Hygiene," by Dr. W. C. Cook, Nashville, Tenn.; "The Clinical History of Continued Malarial Fever," by Dr. B. D. Taylor, U. S. A.;

"A New Method of Detecting *Trichina Spiralis* in Meal," by Dr. James A. Close, London.

Section in General Medicine.

The first paper was read by Dr. Ephraim Cutter, of New York, on "The Morphology of Rheumatic Blood," in which he attributed certain pathological conditions met with in this disease to increased adhesiveness of the blood.

Dr. Mariano Semmola followed with a paper on "Pathogenesis of Albuminuria."

An interesting paper entitled "Notes on the Treatment of Phthisis, more particularly that by Intra-Pulmonary Injection," was read by Dr. R. Singleton Smith, London. The author expressed the belief that benefit was possible by such local medication, and alluded to work already done in this direction by Professor Pepper in Philadelphia and by Drs. Robinson and White in New York. The speaker still firmly believed in the efficacy of iodoform given by the bowel. Its utility is proved by clinical experience. Its feeble powers as a germicide do not affect the question of its medicinal virtues. Intra-pulmonary injections of iodoform are indicated in phthisis, but a suitable solvent for the drug has not yet been found. If a fluid gives rise to much local irritation when given hypodermically, it should not be used for intra-pulmonary injection.

At the afternoon session Dr. Pavy, of London, spoke upon "Diabetes." An abstract of his remarks with the discussion they occasioned, will be presented later.

Following Dr. Pavy's paper, was one by Dr. R. W. Phillips, read by Dr. Stockman, on "The Etiology of Phthisis," in which the author asserted that ptomaines are proved by experiment to be the principal element in the causation of the disease. The author also claimed that injections of atropine counteracted the evil efforts of the ptomaines.

A paper by Dr. W. B. Neftel was then read by the Secretary. It was entitled, "Some Considerations upon the Pathogenesis of the Diseases of Women." The author had experimented to show that phthisis in the lower animals could be caused by compression of the chest. He was unsuccessful in this, but albuminuria resulted from such pressure, which he attributed to venous stasis.

Section in General Surgery.

The first business of the meeting was the discussion of the paper of Dr. Richardson, read on Wednesday.

Dr. Bernays, of St. Louis: I have had a

somewhat similar case to that reported. A tailor swallowed an ordinary silver case-knife, which passed into the stomach. I saw him one hour after the accident, and performed gastrotomy. The incision was made in the linea alba. The knife was found lying transversely, with the handle towards the pylorus. A short incision was made, the knife removed, and the opening in the stomach closed with a double row of sutures. I think that in such cases the continued suture is to be condemned.

Dr. Donald Maclean, of Detroit, said that an important practical point is with reference to the method of restraining hemorrhage. The mortality in olden times was largely due to the defective manner of controlling bleeding. The method described by Dr. Denis seems open to the objection that the elastic band might slip, when the operation was delayed. I have amputated the hip a number of times and have had the utmost satisfaction from the use of Lister's abdominal compressor. I believe that this is superior to any other method for controlling hemorrhage in this region. If the compressor is not at hand, the fists of an assistant will answer the purpose, the compression being made over the umbilicus.

Dr. Weeks, of Portland, Maine, said: I have employed an elastic compressor consisting of the ordinary black rubber bandage, doubled so as to make four strands ten feet in length. This is passed between the thighs, brought between the tuberosity of the inchium and rectum and up in front over the femoral artery. An ordinary roller bandage is placed over the artery. The ends are brought over in front and held by an assistant. This also controls hemorrhage from the gluteal vessels.

Dr. Gunn, of Missouri, said: I understood the author to state that he did not know of a patient with sarcoma of the femur who was alive one year after operation. I assisted in an operation on a case of sarcoma of the lower third of the thigh. Eighteen months later the patient was living and healthy.

Dr. Reyher, of St. Petersburg, said: I think that in emaciated subjects it would not be advisable to make such sudden compression as is caused by Lister's compressor. I have used the rubber tourniquet, but without special satisfaction. I have performed another operation. I make an incision of the head of the bone and then place one stick through the wound and another in front, securing them together by rubber bands. The same thing is done with the posterior portion. The flaps can then be cut without hemor-

rhage. In three operations I have had no disagreeable results from this measure.

Dr. W. Boone, of Shanghai, China, said: No one has alluded to the method proposed by Dr. Furnell Jordan. Where there is sufficient tissue free from disease, this seems to present many advantages. This operation is performed by making a circular cut through the muscles low down, making a flap and then turning back the flap. The bone is next divided. An incision of the head is next made. In this way you cut the vessels low down and the control of bleeding is absolute.

Dr. Palmer, of Jonesville, Wis., said: I have used a method similar to that of Dr. Reyher. Instead of tubes, I have passed pieces of sharpened steel wire through the limb in front and behind the bone and the ring, securing them to other pieces in front of and behind the limb.

Dr. Chavasse, of Birmingham, Eng., said: In amputations for malignant disease, the less tissue left the better, therefore the operation of Mr. Furnell Jordan is not a good one for this particular disease. The best method is that known as Brodies' operation by anterior and posterior skin flaps. In children, the best plan for controlling hemorrhage is by digital compression. This is also applicable in thin subjects. I have also used Dary's rectal staff with satisfaction.

A paper was read on "Iodol" by Assaky, of Bucharest, Roumania. The following are the conclusions of the paper:

I. Wounds unite under iodol by first intention. This union, however, being the result of various and complex conditions attending the operation, it is not possible to attribute to iodol alone the absence of suppuration and inflammatory conditions. In wounds which gape and suppurate iodol is an excellent antiseptic. It rapidly retards suppuration, renders it inodorous, reduces the frequency of dressing, and hastens considerably cicatrization. In ulcerating or gangrenous wounds iodol aids in resisting the destructive process, and changes the wound, after a variable time, to a healthy granulating condition. This action of iodol extends itself to hard chancres. In cases of soft chancres the result is variable. Sometimes it transforms them into a simple wound with brief delay; at others it is insufficient for this purpose, and it becomes necessary to employ in addition, locally, antiseptic lotions.

The same is true with reference to open venereal bubos of the groin. The powdered iodol has this advantage over iodoform, that it is free from odor and is not toxic in its effects.

II. Doses of iodol of from 0.40 centigrammes to 2 grammes daily, produce no functional trouble, even if continued for a long time.

These doses give marvelous results in tertiary syphilis and scrofulous affections. In the secondary stage of syphilis, taken internally, it rapidly destroys the syphilitic manifestations. Iodol seems to aid the general nutrition and increase strength and flesh. It is indicated in all cases of specific malnutrition.

Iodol is an antipyretic. In acute infectious diseases, such as erysipelas, etc., it causes a rapid fall of temperature.

"Paracentesis of the Articulation in the Early Stages of Disease of the Hip-Joint" was the title of a paper by Mr. Edmund Owen, F. R. C. S., London, England.

It is generally admitted that the sero-synovial effusion, associated with early acute disease of the hip-joint, has an influence on the stiffening and faulty position of the limb. In these cases examination will usually show a deep-seated fullness below the middle of Poupert's ligament, which advances the femoral vessels towards the surface. There is also swelling behind between the great trochanter and the tuberosity of the ischium. An illustrative case was given. A boy 9 years of age was admitted to St. Mary's Hospital, London, on account of extreme pain in the right hip and knee. The limb was semiflexed and the foot slightly everted. The attempt to bring the limb down caused tilting of the pelvis and arching of the loins. There were all the signs usually regarded as indicating the first stage of hip-joint disease. There was a slight fullness in the positions indicated. The pain had come on suddenly two weeks previously in a child apparently healthy. Chloroform was administered, but the leg remained stiff. A trocar and canula were passed through the back of the capsule, and a teaspoonful of sero-purulent fluid containing flakes of lymph was withdrawn; the femur could then be extended and the joint was loosened. An extension apparatus was applied and the patient put perfectly at rest. On the fourth day he was free from pain. The convalescence ran a perfect course, terminating in recovery in two weeks.

It may be said that this was not a case of hip-joint disease, but one of simple synovitis. This is admitted, but if the capsule had not been tapped, there might have developed suppurative arthritis. If this is admitted, the author claimed that potential hip-joint disease might be cured by paracentesis.

We should always be on the lookout for this condition. Where we cannot be absolutely certain that there is distension, we should give the patient the benefit of the doubt and perform exploratory puncture. This, if done with clean instruments and ordinary care, is devoid of risk.

Dr. L. H. Sayre, of New York, in opening the discussion, said: I believe that the case which he relates, if allowed to go on, would probably have ended in rupture of the capsule, and perhaps destruction of the head of the bone. In the early stage of the disease when the limb is flexed, everted and abducted as a result of over-distension of the capsular ligament, if the fluid is not absorbed by rest and counter-irritation, it is proper to puncture the joint, thus treating the hip joint the same as any other joint.

Dr. G. W. Boone, of Shanghai, China, said: I think that it is well to report what we can in this connection. Two years ago my attention was called to the injection of joints with glycerine and iodoform. This I used in a number of joints, particularly in two cases where there were evidences of the first stage of hip-joint disease. In one case the symptoms disappeared, while the other case ran the ordinary course of a case of hip-joint disease.

Dr. Lange, of New York, said: In the case reported, the child probably had tubercular disease near the hip-joint, which ruptured into the joint causing effusion. In such a case the painful symptoms can be relieved by tapping the joint. To regard this as an effective treatment for hip-joint disease which must be regarded in children as essentially a tubercular affection, seem hardly proper. This case is not concluded and we do not know what the final result will be.

Dr. Owen, in closing the discussion, said: This was not a case of tubercular process in the joint. The attack began two weeks before admission, was an acute effusion, and recovered within two weeks after operation. Tuberculosis does not run this course.

Dr. Bernays, of St. Louis, in opening the discussion on the paper of Dr. Garmany, read on Wednesday, said: I have had one case of epilepsy and mania for which I trephined. There was a clear history of injury to the head. The skull had been previously trephined without good effect. I also performed trephining; when the bone was removed the dura mater came up into the opening. This I incised and at once there was

an enormous flow of cerebro-spinal fluid. I introduced four catgut sutures to close the opening in the dura mater. The patient recovered, but there was no immediate improvement of the epilepsy, although since then there has been some lessening of the number of the seizures.

"GUN-SHOT WOUNDS OF THE ABDOMEN," was the next paper, and was read by Dr. T. R. Manly, of New York. The case was reported of J. C., brought into the hospital with a pistol-shot wound of the abdomen, in the left epigastric region. The patient was seen two hours after the injury. The abdomen was greatly distended, and evidently contained fluid. The wound was probed with great care, but the place of entrance into the abdomen could not be found. An incision was then made in the linea alba. When the peritoneum was punctured a large amount of blood escaped, estimated to be half a gallon. The hemorrhage was found to come from a branch of the inferior mesenteric artery. This was secured with a ligature. A double perforation was found in the descending colon. This was closed with the Lembert suture, including only the serous and muscular layers. The bullet was not found. The abdominal incision was closed and dressed antiseptically. It, however, failed to unite; in other respects the patient did well. The incision was again closed, the peritoneum being united with a separate row of sutures and the other layers with silver wire. On the third day it was found that the central portion of the wound had opened, but that the peritoneum had united. The patient eventually recovered completely.

The speaker then made some general remarks with reference to operations upon the abdomen. Severe shock should be a contra-indication. Nothing will justify laparotomy when shock exists except positive evidence of hemorrhage. Opening of the abdominal cavity in man is a much more serious operation than in woman. Man habitually uses the abdominal muscles in breathing while in woman, the type of breathing is thoracic. This interferes with the union, and thus tends to make ventral hernia more common in man. In man, the abdominal incision should be no longer than necessary. For exploratory purposes the incision through the linea alba is the best. The drainage tube can serve no useful purpose in the healthy peritoneum free from septic contamination, and interferes with union. Antiseptics should be always used until it is shown that cleanliness will render septic poisoning impossible.

"The use of the Galvano-Cautery Sound, Particularly in Hypertrophy of the Prostate, with Report of Cases," was the title of a paper by Dr. Robert Newman, of New York.

The instrument consists of a smooth sound with a fenestrum at its lower extremity; at this opening is a piece of platinum wire in connection with a galvano-cautery battery. By pressing a key in the handle of the sound the platinum wire is heated to a bright red color. This does not destroy tissue. The instrument is introduced until the lower extremity reaches the prostate gland when the current is passed through the platinum wire. These applications are repeated at intervals of three to five days. The author has employed this method of treatment in fifteen cases, seven of them being cases of hypertrophy of the prostate gland. In all these instances there was improvement in the symptoms presented and a decrease in the size of the prostate.

The next paper was entitled "Endo-cranial Surgery," and was read by Professor Durante, of Rome, Italy. The paper was read in French.

Dr. Carnochan read a paper on "Bony Union After Intra-capsular Fracture of the Neck of the Femur." The doctor presented the specimen from a case of fracture of the thigh bone occurring in an old woman 70 years of age, in which bony union followed rest in bed for a period of nine months.

Dr. Morris, of New York, in opening the discussion, said: The treatment by rest in bed is not to be recommended as a general practice in cases of intra-capsular fracture of the femur. Unless the fracture is an impacted one, there is no hope of union, and the sooner these patients are gotten out of bed the better.

"Ununited Fracture of the Femur Successfully Treated by Double Splice and Wired Clamp," was the title of a paper by Dr. F. Lemoyne, of Pittsburg.

The method of treatment described had been employed in three cases. In two cases, the humerus was the seat of operation, and in the third, the case to be described the femur was the bone operated upon. The patient, a man aged 37 years, was struck by a bucket of ore, receiving a fracture of the left femur, about its middle. This was treated in the usual manner, but union failed to take place. The various procedures employed in cases of ununited fracture, such as drilling, cutting off the ends and wiring, were tried, but no union followed. Eight months after the accident, the mobility at the seat of the

fracture was very distinct. The seat of fracture was then exposed by two incisions, one on the anterior and the other on the external aspect of the limb. The fragments were found attached by five bands of fibrous tissue and the bone itself was softened. The fragments were completely separated and the intervening tissue cut away. The lower extremity of the upper fragment was then sawed off so as to form a wedge-shaped piece. The upper end of the lower fragment was sawed so as to have a corresponding V-shaped depression. The extremities were then brought into apposition. A hole was made in each fragment so that the two openings were $2\frac{1}{2}$ inches apart. A steel clamp, its extremities being bent at right angles, was laid upon the anterior surface of the femur, the ends being inserted into the hole already prepared. This was secured to the bone by three bands of wire encircling the limb at the seat of fracture. The limb was placed on a posterior inclined plane, the foot being elevated about eight inches. Sole leather splints were applied on the external, anterior and internal surface, and the patient was kept as quiet as possible. High inflammatory action with free suppuration occurred. In five weeks there seemed to be some union and the clamp and wire were renewed. The limb was still kept in leather splints. One year after the operation, there was good union; the patient could bear his entire weight on the limb. There was, however, shortening to the extent of two and one-half inches.

In the discussion which followed, Dr. T. R. Manly, of New York, said: I have had considerable experience in wiring the shafts of bones, particularly in fracture of the thigh. If there is much shortening, I think we should wire the bone at once. We do no harm by making a free incision down to the bone and the silver wire causes no irritation. I leave them in permanently and the results have been satisfactory.

"Wire Extension Splints in the Treatment of Fractures Near the Joints" was the next paper by Dr. Gibson. Several wire splints intended to be used in the treatment of the fractures of the thigh, fractures near the head of the humerus and Colles fracture were exhibited. The author claimed for these efficiency and comfort. He recommended their use more particularly in cases of fractures near the joints.

Dr. Myres, of Fort Wayne, in beginning the discussion, said: I think that the best dressing for fractures that we now have is plaster of Paris and crinoline. When properly applied immediately after the reception of the

fracture it answer every purpose. It is less inconvenient than other dressings and the results obtained are satisfactory.

Dr. S. S. Koser, of Williamsport, read a paper on "Splint for Fracture of the Lower Jaw." The speaker reported a case in which the lower jaw was fractured through the symphysis and one inch to the left of the symphysis with separation of both processes on the left side. Various forms of splints were tried without satisfactory results. An intra-dental splint was then made to which was attached steel arms projecting from the sides. An external rubber splint was then made and the two splints secured together. This held the fragments in position and good union was obtained.

Section in Obstetrics.

Dr. Alex. Simpson, of Edinburgh, took the chair in the absence of Dr. Miller, who had been called away by a death in his family. The section passed resolutions of sympathy with him.

Dr. Emil Poussie, of Paris, France, then read an account of a case of "Typhoid Fever in the Puerperal Woman," in which a woman, seven days after labor, presented symptoms of severe typhoid fever. The patient recovered.

A discussion then took place as to the best method of preventing and treating puerperal fever, in which a large number participated.

Dr. Rodney Glison, of Portland, Maine, read a paper on "Conservative Obstetrics; with Special Reference to the Removal of the Secundines after Abortion, and to the Treatment of the Third Stage of Labor." The author favors the prompt removal of the placenta after abortion in all cases in which the cervix is dilatable or dilated; in all cases of septicemia and in dangerous hemorrhage, whenever the latter two occur. For this purpose the finger is the best instrument. Traction on the cord, while the uterus is grasped with one hand externally, is not apt to cause inversion of the uterus and is a useful aid in extraction of the placenta, that should not be forgotten nor neglected.

Dr. Grailly Hewitt expressed approval of the author's practice.

Dr. E. H. Trenholme, of Montreal, Canada, read a paper on "Internal Uterine Hemorrhage the Result of Over-distension of the Uterus from Hydramnios," in which the author referred to the causes of hydramnios and the dangers of distension caused by it. One of the latter was serious interference with the nutrition.

Dr. W. T. Stewart, of Philadelphia, read a paper on "The Importance of Accurate Diagnosis in Pregnancy," in which he reported a case of retroflexion of the uterus in which labor occurred at term. It had been supposed by a number of physicians that the patient was suffering from a fibroid tumor, for which she came near being operated on. The speaker also referred to the injurious effects of corsets.

Dr. John Bartlett, of Chicago, Ill., followed with a paper on "A study of Deventer's Method of Delivery of the After-coming Head." This method consists in turning the child so that the anterior surface of the neck rests on the perineum and bringing the occiput out under the pubes. The arms are not brought down, but are placed so as to come anterior to corresponding parietal bases. In addition to backward traction, delivery was to be assisted by pressure just above the pubes.

Deventer is said never to have lost a child or torn a perineum in using this method. The object of leaving the arms up was to protect the neck and at the same time to allow room for the cord.

In the discussion which followed, the speakers all seemed favorable to the procedure.

Dr. J. E. Kelly then read a paper upon "Lithiasis in Pregnancy," in which he discussed the relations between lithiasis and pregnancy, and came to the conclusion that the pregnant state gave rise to a condition that was to all intents and purposes lithiasis.

Dr. E. P. Christian read a paper on "The Proportion and Causes of Still Births," in which he stated that the average of deaths for States and countries was about four per cent., while for large cities it was seven per cent. He also stated that syphilis, drunkenness and ergot were the chief causes of death.

In the discussion which followed, both Professor Simpson, of Edinburgh, and Drs. Dunmire, Lester, Stewart, Robinson and Salle, all agreed with the author in his condemnation of ergot.

Section in Diseases of Children.

Dr. Albert R. Leeds, of Stevens' Institute of Technology, read the first paper on "The Nutrition of Infants."

Professor D'Espine, of Geneva, had the next paper, which was read by Dr. Cordes, of Geneva, on "Observations on True or Lobar Pneumonia in Children." He described three forms which he thought were specially characteristic in children.

Dr. Henry Ashby, of Manchester, England, read a paper on "Scarlatinal Nephritis from a Clinical and Pathological Standpoint," in which he stated the results of his personal experience in fifteen hundred cases of the disease that had occurred in the Pendlebury Hospital for Sick Children in the last eight years. He finds that the first and most characteristic symptoms are diminished quantity of urine and puffiness under the eyes. In cases that recover, the urine continues to diminish and the puffiness to increase until an abrupt crisis occurs, when a large quantity of smoky urine of low specific gravity is voided and convalescence begins.

Dr. Frank Grover, of New York, read a paper entitled "Anatomical Characters of Scarlatinal Nephritis."

Section in Ophthalmology.

Professor X. Galezowski, of Paris, France, read the opening paper on "The Curability of Detachment of the Retina," in which he proposed the operation of sub-retinal aspiration, believing that effusion exists behind the retina. By this method he claims to have cured two out of seventeen cases. He only did the operation in bad cases.

Dr. J. A. S. Grant (Bey), of Cairo, Egypt, read a paper by Dr. Burgsch (Bey), of Cairo, on "The Predisposition to Glaucoma," in which it was stated that Semitic races were decidedly predisposed to the disease. It occurs four times as often in the Semitic race as in the other races.

At the Afternoon Session, Dr. A. G. Sinclair reported a case of "Retinal Glioma on Both Sides." These tumors occurred in a young child, who remains well, though the operation occurred six years ago.

Dr. H. C. Paddock, of New York, followed with a paper on "Ergot in Ophthalmic Practice," in which he advocated the use of ergot in congestive or inflammatory diseases of the eye, on account of its physiological action in constricting blood vessels and contracting unstriated muscular fibre.

Dr. Power read Dr. P. H. Mule's paper on "Evisceration and the Artificial Vitreous," in which a new operation for which improved results were claimed, was advocated.

Dr. R. L. Randolph, of Baltimore, Md., read the paper of Dr. Gifford, of Omaha, on "Further Contributions to Sympathetic Ophthalmia," which seemed to demonstrate the existence of a current from the fundus of the eye to the brain, apart from the channels of the optic nerve.

Dr. J. R. Cross, of Bristol, England, presented a paper on "Retinoscopy; It Promises

a Rapid and Reliable Method of Estimating Errors of Refraction, and is a Test of the Greatest Practical Value."

Another paper on "Retinoscopy" was presented by Dr. A. R. Baker, of Cleveland, Ohio.

Section in Dermatology and Syphilography.

Dr. P. G. Unna, of Hamburg, Germany, read the opening paper on "Seborrhœal Eczema," in which he stated his opinion that all so-called dry seborrhœas were chronic inflammatory processes. He regarded seborrhœal eczema as a disease resulting from a change in the coiled sweat glands, as a result of which they secrete fat. There are three kinds, the first beginning as a latent catarrh of the scalp; the second occurs as an accumulation into fatty crusts between the hairs, causing the latter to fall out; the third form consists in a moisture or "weeping," especially about the temples and eyes.

Sulphur is the best remedy for this disease.

Dr. Rohé, of Baltimore, Md., then presented a patient with multiple sarcoma of the skin.

Dr. A. R. Robinson, of New York, reported a case of "Progressive Melanosis of the Skin."

Dr. Ohmann-Dumesnil, of St. Louis, then read a paper on "Double Comedo," in which he stated that he had found comedones double in two and one-fourth per cent. of all cases in hospital practice in male patients.

In the discussion, Dr. Unna said he did not believe that double comedo ever occurred in a completely healthy skin, but that there must have previously occurred some inflammatory process followed by cicatrization.

"The Treatment of Syphilis by Injection of Insoluble Salts of Mercury" was the title of a paper by Dr. H. Watraszewski, of Warsaw, Poland, in which it was stated that the author preferred the use of the yellow oxide of mercury. He claims that only from twelve to twenty injections are required for a course of treatment, and that four or five suffice to cause the disappearance of any lesion that may be present. The injections are given once a week. The following is a formula:

R Hydrarg. ox. flav. gr. xv
Gummi arab. gr. iv
Aque destillat. f 3 j
M.—Shake before injecting.

Section in Laryngology.

Dr. W. E. Casselberry read the opening paper on "Nasal Fibromata." He said that they should be thoroughly removed and their bases cauterized, as they are apt to degenerate into sarcomata.

Dr. John O. Roe, of Rochester, N. Y., followed with a paper on "Chorea Laryngis," in which he reported several cases in which this had occurred, generally in the course of general chorea. Treatment should be constitutional. In the discussion which followed, Dr. Thorne, of Cincinnati, Ohio, reported a case occurring in a pregnant woman.

Dr. M. F. Coomes, of Louisville, Ky., read a paper on "The Deleterious Effects of Tobacco on the Throat and Nose." The bad effects he found to be particularly noticeable in cigarette smokers.

Dr. Max. J. Stern then read a paper on "Intubation or Tracheotomy," in which he argued from statistics to show that intubation was followed by a lower mortality than tracheotomy.

Section in Dental and Oral Surgery.

The members of this section were given every opportunity to study the microscopy of the teeth. A number of very successful clinics were also held.

Dr. C. T. Goddard, D.D.S., of San Francisco, Cal., read a paper on "Pain in the Temporo-Maxillary Joint Caused by Irregularity of the Teeth." The pain was relieved by altering the teeth so that apposition was possible.

Dr. E. S. Chisholm, of Tuscaloosa, Ala., read the next paper, which was entitled "The Influence of Weather Changes on the Human Organism," which was an argument to show that atmospheric influences effect greater changes upon the human organism than any other one cause.

At the Afternoon Session, Dr. U. S. Davis was introduced by Dr. Taft as the man to whom the credit should be given for obtaining recognition for dentists by establishing the Dental Section. Dr. Davis replied in suitable terms.

Dr. E. S. Talbot, of Chicago, read an instructive paper on "The Etiology of Irregularities of the Jaws and Teeth."

Section in Climatology.

Dr. T. M. Coan, of New York, read the first paper, which was entitled "American Mineral Waters, with Remarks on Climate;" a literary notice of this paper appeared in the preceding number of the REPORTER.

Dr. R. J. Munn read the next paper on "A Contribution to the Study of Climatic and other Peculiarities of Localities which Determine Exemption from Endemic Plagues." The locality particularly studied was Savannah, which seems to be exempt from certain diseases.

Section in Gynecology.

Dr. Ephraim Cutter, of New York, read the first paper on "Galvanism for Uterine Fibroids," in which he claimed priority for the operation, and criticized Apostoli. The paper gave rise to some feeling, which seemed rather adverse to the speaker.

At the Afternoon Session, two papers were read on the subject of "Hysterectomy for Uterine Cancer" by Drs. A. Reeves Jackson, of Chicago, and A. Martin, of Berlin. The papers took decidedly opposite grounds and from the interest of the subject and the fame of the debaters attracted quite a good deal of interest. We give below a synopsis of the two papers with the discussion which followed:

The subject of Dr. Jackson's paper was "Modern Treatment of Uterine Cancer." The paper was a very logically written one, in which the author maintained that correct views as to the pathology and accurate diagnosis were the safe guide to proper treatment. The local origin of cancer, which implies the possibility of its removal, is the basis of the modern treatment. This theory true, failure to cure depends on inefficient or untimely employment of the remedies. All means are inadequate which do not thoroughly remove the diseased structures. The location of the disease or the condition of the patient may demand palliative or radical treatment. Palliative measures are always available while radical measures are not always safely applicable. Medical agents taken internally may be beneficial as palliatives, but are useless so far as we know in removing or modifying the progress of disease. For this purpose we can rely only on topical treatment. Topical means comprise various astringents, detergent and anodyne agents as palliatives; and for the partial or complete removal of the disease, caustics, the cautery (thermo-galvanic) scraping, gouging or cutting instruments. Results have been obtained by the use of these agents, singly and variously combined. The author then mentioned the reasons why operative measures so frequently fail. The question of hysterectomy was then considered. Statistics of the operation and their fallacies were also given. The following were his conclusions:

1. Any operation for cancer which does not completely remove the disease will be followed by recurrence.

2. During life, the limit of cancerous disease originating in any part of the uterus cannot be known; hence no operative procedure can guarantee complete removal.

3. In view of this fact no operation is justifiable which greatly endangers life, provided other and safer methods are available.

4. Vaginal hysterectomy is more dangerous in a certain sense than the disease against which it is used; that is, a given number of patients afflicted with uterine cancer will live longer without than with the operation.

5. Other methods of treatment attended by not more than one-sixth to one-fourth the mortality of vaginal hysterectomy, are equally efficient in ameliorating the symptoms and retarding the progress of the trouble; and they have been followed by as seemingly good results as regards recurrence. Hence they should be preferred.

6. Vaginal hysterectomy does not avert or lessen suffering; it destroys and does not save life. It is therefore not a useful but an injurious operation, and as such is unjustifiable.

The paper of Dr. Martin was an eminently learned one and brimfull of experience. The well known fame of this operator drew out a large representation. The subject was "The Vaginal Total Extirpation of the Cancerous Uterus."

He first discussed the inauguration of this operation which was first performed by Freund about ten years ago. Since that time sufficient material has accumulated to decide the two questions which may be asked concerning every new method of surgical treatment.

1. Is this operation practicable with such immediate success that it promises good results in the hands of others than those who are especially successful operators?

2. Does the extirpation of the cancerous uterus give permanent results which force us to recognize that this method is superior to any other treatment of cancer employed up to the present time?

In seeking an answer to the first, if we examine the literature we are struck with the fact that only meagre and isolated reports about this operation can be found in English and German medical journals. Vaginal extirpation has obtained decided recognition in Germany. In that country the purely vaginal operations of Czerny and Billroth and Schroeder has been adopted instead of the procedure of Freund, which was a combination of abdominal and vaginal operations. The results of the same have improved noticeably with increasing exercise and experience.

In 1881 Olshausen collected 41 cases with 29 per cent. mortality. In 1883, Säger 133 cases, 28 per cent. mortality. In 1884, Eng-

ström 157, with 29 per cent. mortality. 1886, Hegar 357 with 28 per cent. mortality.

Through the courtesy of these operators, who to my knowledge commanded the greatest amount of material, and at my request placed at my disposal the results up to the end of the year 1886, I am able to construct the following table:

Table I. Up to the end of 1886 these total extirpations have been performed on account of carcinoma uteri: Fritsch, 60 times, with 7 deaths; Leopold, 42 times, 4 deaths; Olshausen, 47 times, 12 deaths; Schroeder (Hofmeier), 74 times, 12 deaths; Staude, 22 times, 1 death. A. Martin, 66 times, 11 deaths. Total, 311 cases, with 47 deaths or 15.1 per cent.

Are we not justified in assuming that this rate of mortality will increase with more experience, as shown by the published tabular results of each of these operators? Already the total extirpation of the uterus for cancer shows better results so far as immediate mortality is concerned than removal of the breast for cancer.

For the latter, Kuster at the 12th meeting of the German Surgical Society in 1883, published 778 cases with a mortality of 15.6 per cent. Who would hesitate to propose to perform the amputation of the cancerous breast so soon as the diagnosis is established?

I do not hesitate to answer my first question in the affirmative, and to claim for this operation of the vaginal total extirpation of the uterus a full and equal rank among all methods for the treatment of cancer of this organ.

For an answer to the second, we will make use of the relatively small, but very accurately reported cases of Schroeder, collected by Hofmeier and those of Fritsch, Leopold and myself; they are brought together in the following table:

Table II. demonstrates by permanent results that vaginal total extirpation, in this relatively short period of observation, gives results equal to the best results of carcinoma operations of other organs.

The author up to the end of 1885 operated on 44 cases; of these 18 or 29.7 per cent. relapsed; 31 or 70.8 per cent. recovered.

Is there any other method of treating cancer which, with so small mortality, can show equally good results? There is no other mode of treating cancer of the fundus and those forms of disease of the cervix in which the mucous lining of the cervical canal is the point of origin, or in which there are carcinomatous nodules in the tissues of the

neck. There is no room for discussion, except in epithelioma of the portio vaginalis, arising from the surface of the cervix; that is from a surface covered with flat epithelium and containing very few glands.

This form, according to Ruge and Veit and Schroeder and Hofmeier, has an essentially less malignant character than the above mentioned forms of carcinoma of the neck. According to Hofmeier the high excision for epithelioma of the cervix has shown a mortality in the operation of 7.4 per cent., and a recovery of 58 per cent. for the first year and 38 per cent. after four years.

That relapses are not prevented by this operation is expressly stated in Hofmeier's communication, and therefore it cannot be maintained that high excision is a safe means for treating this form of epithelioma of the cervix. My own experience in 23 cases of high excision was that 6 died under the influence of the operation, but all of the survivors relapsed in a short time; only a few lived to the end of the second year.

I agree with Fritsch that the observation of cases as to progress of the disease in isolated nodules in the mucous membrane up to the fundus, in cases of carcinoma colli, is sufficient in itself to show that it is erroneous to claim that in carcinoma of the cervix we should try to save the body of the uterus. Binswanger and P. Ruge have described such well-marked cases.

The possibility of a subsequent pregnancy is not excluded in cases of high excision; but Hofmeier himself declares that pregnancy is a very serious danger in carcinoma. Therefore I am convinced that it is much better to immediately perform vaginal total extirpation in these forms of epithelioma of the cervix. The sooner we operate the more surely we may hope to save our patients from the sad fate of death by cancer. The greater the experience with vaginal total extirpations, the more has the rule been proved that we shall perform the operation only when the vicinity of the uterus is entirely free from carcinomatous infiltration. All attempts to enlarge the boundaries of the operation in this direction have failed. It becomes more difficult through such infiltration, the danger increases, and there can be no hope of a permanent cure. The majority of operators, so far as I can learn, have concluded, as I have, not to expose these cases to any attempt at a radical operation.

If the carcinoma appears in the form of a solid infiltration of the ligaments and the walls of the vagina, then the diagnosis and decision present no difficulties. The progress

of the disease by means of lymphatics is often impossible to discover before the opening of the roof of the vagina. Such cases then are not dangerous so far as the operation is concerned, but hopeless as regards a permanent cure. They should be put in a separate column in summing up the permanent results of the operation.

Cicatrices on account of former inflammations in the floor of the pelvis may make the procedure exceedingly difficult and aggravate the prognosis through the shock of the operation, which is often very serious. One should venture to operate in such cases only if there is strong indication for interference and reasonably great experience on the part of the surgeon.

The technique of the operation has undergone only immaterial changes, as is shown by the results of operators using different methods. It is irrelevant whether the uterus be relieved by an incision made in front of, or at the side of the neck, or behind it. It is of little importance whether hemorrhage be prevented by stitches introduced before the incision, or whether each separate vessel be seized and tied as it bleeds. It is immaterial whether the uterus be turned over or removed by drawing it down and freeing it; whether the opening in the floor of the pelvis remain open or be closed, or be drained either with the iodoform gauze or with a tube.

If it be easily practicable I advise that the ovaries and tubes be also removed. It is immaterial whether the wound be sutured or not. It is wonderful what little impression the operation makes on the patient. One can liken her very much to a puerperal woman.

Bleeding must be stopped, at all events, during convalescence; the parts as much as possible kept at rest. Washing out the peritoneal cavity does not work favorably. However the opening in the floor of the pelvis is treated, a smooth scar is finally formed into which the roof of the vagina curves upward. If the patients do not become septic or get any other complication, they make an extraordinarily rapid recovery. They regain health and strength, and after the symptoms of the sudden change of life have been overcome, they seem to enjoy life fully. There is no observation showing that after removal of the uterus, without the tubes and ovaries, the patients lose their sexual feelings or their peculiar feminine form.

I recommend the vaginal extirpation, as the means which we ought to employ, in cases of cancerous diseases of the uterus, as long as the disease is limited to the uterus itself.

Dr. Martin, in opening the discussion on Dr. Jackson's paper and his own, further said: I am accustomed to prepare my patients for operation with the most thorough antiseptic vaginal injection. He then described most minutely his method of operating. He very frequently opens Douglas's pouch at one stroke of the knife. You then see the posterior fornix and cut carefully, paring with the finger nail. When the peritoneum is opened, I introduce one finger into it, and have warm water running over the surface, and do not use sponges. I suture the vagina to the peritoneum. When I have freed the broad ligament, I cut it from the uterus and generally have no hemorrhage. I then proceed in like manner on the other side, till I have the broad ligament severed there also. Up to this stage there is very slight hemorrhage. I then commence on the bladder, freeing it with the forceps or the knife. After it is freed, I unite the cut border of the vagina with the peritoneum just as I did before. I am accustomed to put a drainage tube of India-rubber into the peritoneum. I think it does good, although I must confess that I believe that a case which is not infected should be closed up. Yet I have had such good results from this that I still use it. There are various gentlemen present who have seen me operate and who can testify that I lose a very small amount of blood. Of course, there are cases where loss of blood is necessary from the existing conditions. The operation is yet new; it has only been done for three years, and I think we will improve on it very much. We should not proceed to operate unless we know the cancer to be limited to the uterus. Most operators in Germany agree with me on this point. We should not go by the statistics of several years ago; we are doing better every year from the collected experience. The operation has been performed for procidentia, myomata and other complaints. Dr. Jackson cites an apparent difference in my statistics. I differentiate between cases which are limited to the uterus and which are not so limited. In only 36 cases of mine has it been proved that the disease was limited entirely to the uterus. I think that the statistics of the operation will not yet allow that it be condemned. We should go on with our work gathering experience, and I think we will receive the applause of future generations. Dr. Martin then showed specimens which he had brought with him from Berlin of cases which he had operated upon.

Dr. D'Arny, of Hungary, gave a history of

his experience with 12 cases. Out of these 12 cases only 2 are now living, after a period of 3 or 4 years. As to the operation, he thought that the best we could do was to close the opening into the pelvis and vagina with iodoform gauze and let the patient alone. As to Dr. Jackson, he thought he was on the wrong road with his statistics. Statistics deal only with quantity, not with quality. If there are 100 persons on a ship, possibly I could only save one of them. Should I not save this one? Certainly. Patients suffering with cancer of the uterus are shipwrecked persons, and sure to die a most painful death. We can save a number of our patients, and those who die usually die in a short time and have comparatively comfortable deaths. Humanity demands of us that we do the operation of vaginal hysterectomy in all cases in which we can remove all of the diseased tissue.

Dr. Dudley, of New York, wished to enter a plea for vaginal hysterectomy for uterine cancer in America and point out why the operation had been less successful here than in Germany. Martin had 66 cases with 11 deaths. In a paper read by the speaker some timesince, he reported 66 cases with 34 deaths. These 66 cases however were divided between 34 operators, and here lies the difficulty. Experience is a good teacher, and practice makes perfect. The child must creep before it can walk; and the surgeon must have a fair trial, especially in America. As in the case of ovariectomy, which originated in America, our surgeons are almost flocking to Europe to learn how it is done. The amount of pain and suffering in the death of the patient is one of the points which should induce us to try this operation. The doctor then showed some pictures on a screen relating to the discussion.

Dr. Nunn, of Savannah, Ga., said that there was always a starting point to cancer. It is generally due to neglect of fissures or some other irritant, arising consequent to parturition. In his own practice he has his patients report to him occasionally after delivery to see that they take care of themselves properly, and had not had a case of cancer in his own patients.

Dr. Graily Hewitt, of London, said that the whole civilized world, and the uncivilized, too, are under obligations to Dr. Martin and his colleagues for their work in this line for having advanced the operation to its present state. In a discussion in the London obstetrical society a few years ago I was the only one who refrained from condemning the operation. I think it should be done in

properly selected cases by gentlemen of experience.

Dr. Cutter, of New York, regarded cancer as a disease of nutrition, and recommended a diet of beef and milk.

Dr. A. Reeves Jackson, of Chicago, thought it wrong to attempt to reason against facts, as well as difficult. His paper was based on facts founded on the results of Gausserow, Paget and such men. These gentlemen had estimated the duration of life in those women suffering from uterine cancer to be 21 months as an average. If this be true, then my calculation as to the duration of life will not be denied. The average duration of life of women operated upon is 14 months; this difference in the aggregate amounts to nearly 800 years of grand total loss of life. Does anybody allege that it has saved life? Dr. Martin claims that the operation should be done only when the disease is limited to the uterus. How does he know that the disease was limited to the uterus, because it did not return? Baker, of this country, by his high operation has 60 per cent of recoveries, which is far better than Martin's.

Dr. Martin replied that he knew that a cancer was limited to an organ by its having a layer of entirely healthy tissue around it.

Section in Anatomy.

Dr. M. J. Roberts, of New York, read the opening paper on "The Fundamental Anatomico-mechanical Considerations Underlying the Successful Treatment of Deformities, Diseases, and Weaknesses of the Spine." In this paper the author recommended wire corsets as the best contrivance in Pott's disease.

At the Afternoon Session, Dr. W. X. Sudtho, of Philadelphia, read a paper on "The Development of Bone." He declared that the white blood corpuscle was the basis of all connective tissues, and that osteoblasts never ossify.

Dr. N. Stamm, of Fremont, Ohio, read the next paper on "The Anatomical Points of Value in the Diagnosis of Some Joint Affections." The author referred at length to the anatomy of the synovial sac.

Dr. Benjamin Lee, read a paper on "A Case of Deformity of the Spinal Column Produced by Maternal Impression on the Fetus," which treated of a case of vertebral disease.

Section in Psychological Medicine.

Dr. S. S. Bishop read the opening paper on the "Pathology of Hay Fever," in which he expressed the opinion that this disease was catarrhal, and of nervous origin.

Dr. Elliott, of New Haven, read a paper on "The Treatment of Neuralgia," for which disease he used morphine largely. In the discussion which followed, most of the speakers were opposed to the indiscriminate use of morphia.

Dr. Russell followed with a paper on the "Borderland of Insanity," in which he strove to show that epilepsy and such like diseases did not result in mental weakness.

Dr. Fisher read the next paper on "Nursing Reform."

At the Afternoon Session, the first paper was "Insanity as a Defence for Crime," by Dr. W. W. Godding.

This was followed by a discussion upon Syphilis Associated with General Paralysis, in which Dr. Savage, of London, lead.

Professor Mendel then presented an address on "Moral Insanity," in which he urged that the term should be stricken from the category of mental diseases.

FRIDAY, SEPTEMBER 9.

At the General Meeting in the morning, after some announcements had been made, Dr. Hamilton reported that the committee appointed to select the next meeting place for the Congress had chosen Berlin, Germany, and the time as 1890.

Dr. Hamilton also reported a recommendation in favor of uniformity in reports of sick and wounded in all the armies of the world.

Resolutions from the section in Hygiene and public medicine were also offered, calling attention to the frequency of railroad casualties, and recommending greater attention to sanitary laws by railroads.

Resolutions were also reported from the same section, recommending the co-operative investigation of the results claimed by Dr. Freire to result from inoculations of yellow fever.

Dr. Charles D. C. Phillips was then called to the chair by Dr. Davis, while Dr. G. F. Blandford, of London, delivered an address on "The Treatment of Recent Cases of Insanity in Asylums and in Private Houses."

The author devoted his study to recent cases of insanity, and stated that the question whether such insanity should be treated in an asylum or in a private house was largely decided by the question whether or not confinement in an asylum would damage the patient's future prospects, financially or socially.

Attacks of maniacal excitement are likely to be of short duration, and may result from drink, or from shock in a neurotic person.

Prognosis as regards recovery is good, but the duration is doubtful. Attacks of melancholia are of long duration, and suicide is common. This can only be prevented by unremitting watchfulness on the part of attendants, which can be done in a private house as well as in an asylum. But if food has to be forced upon a patient, a number of assistants such as are to be had in an asylum will be necessary.

Acute primary dementia may also be treated successfully out of an asylum. A final point to be considered in deciding to keep a patient in a private house or to send him to an asylum, is the question of funds. It costs much more in a private house. Where means are slender, the patient should be sent to an asylum.

A vote of thanks was unanimously given to Dr. Blandford, at the conclusion of his address.

Section in General Medicine.

The first paper was read by Dr. G. E. Stubbs, of Philadelphia, whose subject was "Rational Treatment of Diseases of the Respiratory Apparatus." The author stated his preference for local counter-irritation in phthisis.

Dr. Eye, of Reading, Pa., read the next paper on "A New Method of Treatment of Phthisis," in which he recommended the inhalation of the gases generated by adding the white of one egg to six or eight ounces of water and keeping the mixture in a bottle for four or five days. He reports favorable clinical results from this use.

Sir James Grant, of Canada, then read a paper on "Diphtheria," in which he divided the disease into the simple and the malignant. The disease is a blood poisoning. At the beginning of the attack he uses baths of one ounce of mustard to a quantity of water contained in an ordinary bath-tub. Following this bath, the patient is wrapped up and diaphoresis encouraged. In the malignant type of the disease, treatment seemed unavailing. The author stated, also, that when there is a large snow-fall and consequent dryness of the atmosphere, diphtheria is less prevalent.

At the Afternoon Session, Dr. Ouchterlony reported very favorably on behalf of the committee appointed to examine Dr. Körösi's paper on the "Preventive Power of Vaccination."

Dr. A. B. Arnold read a paper on "Dilated and Fatty Heart."

Dr. Geo. E. Fell, of Buffalo, N. Y., read a paper on "Forced Artificial Respiration in

Opium-Poisoning; its Possibilities and the Apparatus best Adapted to Produce it," in which he advocated tracheotomy and artificial respiration with bellows.

Section in Surgery.

The first paper was entitled "A New Method of Operation on Bone," and was read by Milton J. Roberts, of New York. The author demonstrated his electric-osteotome, which consists of an electric-motor to which may be attached trephines and circular-saws of various sizes. By means of an attachment a saw is used having a to and fro movement. The motor is run by a storage battery. There is also an electric light with a mirror attached to the motor by which light is thrown on the part operated upon. In addition there is also a spray-apparatus operated by compressed air, by which a constant spray is thrown upon the saw while in operation. This is found to facilitate the cutting. All the various attachments are under the control of one hand.

Dr. George E. Post, of Beirut, Syria, read a paper on "Calculus in Syria." Stone is a common affection in almost every part of Syria and Palestine, but more frequent in certain villages than in others. The proportion of large stones is greater than it is either in Europe or America. This is to be explained by a number of causes, among others the prejudice against surgical operations, the want of skill on the part of surgeons, the ignorance with reference to the use of the sound and the poverty and ignorance of the people, leading them to postpone operation as long as possible. To these is to be added the traditional faith in the solvent power of certain substances. The native surgeons in operating practice median lithotomy. The patient is placed on his back in the lithotomy position, without anæsthetics, and one or two fingers are introduced into the rectum. The stone is pushed forward with the fingers until it impinges on the perineum. The operator then cuts with a razor or a scalpel directly on the stone, the cut extending from a little behind the scrotum to within the anus, laying open not only the perineum but also the lower portion of the rectum, and the stone pops out. This method of operation is of course productive of many cases of fistula of various kinds. There is also considerable risk from hemorrhage. In one case operated on in this way in infancy, the author found three stones in the scrotum and two in the perineum.

The largest stone removed by the speaker weighed about twelve ounces. It was four

inches in length, three and one-half in breadth, and nearly two inches in thickness. This stone was removed by perineal lithotomy, and it was necessary to cut the prostate on both sides and also in the middle. The patient from whom this stone was removed did well for fifteen days, when as a result of imprudence in diet he was attacked with a colliquative diarrhea and died seven weeks later from exhaustion. There were no unfavorable symptoms connected with the wound. The greatest number of stones removed from one patient was two hundred, but many of these were merely granules. In one case there were eleven stones of nearly equal size and weighing in the aggregate about six ounces.

The author had operated on two hundred and fifty cases. Less than one-half of the stones were composed of phosphates, over one-third consisted of uric acid and urates, and of the remainder the most consisted of oxalate of lime, with a few carbonate of lime stones. One hundred and seventy-six of these cases were operated on by perineal lithotomy. Of this number, ten cases proved fatal; 106 of the 176 were in children less than ten years of age. Two of these children died—one of erysipelas, and the other of shock. The remaining 70 cases were between 11 and 75 years of age, and, of this number, 8 died; four of the fatal cases were between 65 and 75 years of age. In 44 cases, lithotripsy was employed, with a fatal result in 4 instances. Of the 250 cases, eleven of the patients were females.

Two cases of urethral stone were reported. The first was that of a man of seventy with phimosis. A stone was found at the meatus, and removed. A second was found four inches from the meatus. This was also removed. A third stone was detected in the membranous portion of the urethra, but during the manipulations it passed into the bladder. Two or three days later it was caught with a lithotrite, and removed. The second case occurred in a child two years of age, who was brought to the speaker on account of total retention of urine. The distended bladder reached above the umbilicus. An obstruction was found at the neck of the bladder, but it was found possible to pass a catheter over the obstruction. The urine was drawn for several days. It was then decided to make an exploratory section, but when the time for operation arrived it was found that the stone had been dislodged, and was at the meatus. It was then removed without difficulty.

Dr. J. S. Grant (Bey), of Cairo, Egypt, in opening the discussion, said: I have listened with much interest to the paper, and it may be of interest to say something with reference to stone in Egypt. This is a very common affection in Egypt, where we have another common disease, that is, Bilharzia hæmatobia. Certain investigations seem to show that the germs of this disease have something to do with the causation of stone. Sections of calculi have revealed the presence of the germs of this affection. The following case recently presented himself to me: The patient, a railroad employé, came with considerable inflammation of the scrotum and with a fistulous opening entering the scrotum. A large scrotal calculus could be readily seen. Six years previously the patient had suddenly had retention of urine. This continued ten days, and the trouble then suddenly disappeared. After this he noticed that the scrotum was gradually increasing in size, and made a large incision through the fistulous opening and removed from the scrotum a stone weighing fourteen ounces.

In Egypt we do not have the class of stone cutters referred to by Dr. Post. Egypt is divided into fourteen provinces, each of which has a hospital under the charge of a competent physician.

Dr. Oscar J. Coskery, of Baltimore, reported a case of "An Uncommon Fracture with Dislocation of the Tarsus and Metatarsus."

Following this, a paper was read on "Elastic Contraction of the Neck, with Exclusion of the Trachea as a Means of Controlling Hemorrhage in Operations on the Head," by N. Senn, M. D., of Milwaukee, Wis. The author referred to the many advantages derived from the use of the Esmarch bandage in operations on the extremities. In the case of the head where bloodless operations are most desirable, we have, so far, not been able to attain that result. The principal objection to constriction of the neck appears to be the necessary compression of the trachea. It is also possible that the pressure on the pneumogastric and phrenic nerves may interfere with respiration. The author had taken dogs, and isolating the trachea had passed an elastic bandage around the neck between the œsophagus and the trachea. This produced no immediate effects on respiration. In one case the dog was allowed to live two hours with the band around the neck and no blood going to the brain with the exception of that which reached it through the vertebral

arteries. This animal was allowed to live and presented no subsequent symptoms. It was found that after the band was applied the lingual, the external, the internal and the common carotid could be divided without any escape of blood from the proximal extremity. The only arterial hemorrhage was from the peripheral and through the collateral circulation. There was some venous engorgement, and as a consequence a certain amount of venous bleeding. By this method we can extirpate the tongue, excise the upper jaw, perform radical operations on aneurisms, especially on aneurisms by anastomosis, and do other operations that could not be done without it.

"Congenital Dislocation of the Heads of the Femora" was the title of the next paper by Dr. Carnochan, of New York.

Reference was made to the general lack of knowledge concerning this malady. The affection is, however, not an infrequent one. The author had seen seventy-five cases during the past twenty-five years. Drawings from several cases of this kind were exhibited, showing the peculiar deformity which this malady produced. The pelvis and femora taken from an individual sixty years of age, who was the subject of congenital dislocation at the hip-joint, was shown. There were marked changes in the structures of the heads of the thigh bones and also in the acetabula, which were simply triangular cavities. As to the cause of this condition, it was uncertain whether it was due to rough handling or to want of nutrition.

Dr. Morris, of New York, in opening the discussion, said: It is evidently not due to rough handling; for it is quite frequent in the Northern part of Germany where women receive skillful attention during confinement. The deformity is quite frequent where rachitic affections abound.

Dr. George E. Post, of Beirut, said: I see this condition quite frequently. While one class of cases may depend on rachitis, there is another class in which the condition is evidently the result of mechanical causes. In a recent case I found the head of the femur in the thyroid foramen. There was no history of injury. I can only explain these numerous cases disassociated from scrofulous and rachitic affections as due to some movement of the child in utero.

Dr. Spanton, of Hanly, England, exhibited a pad for retaining the discharges in cases of faecal fistula.

Dr. Arthur H. Wilson, of Boston, illustrated with the stereopticon, certain histologicopathological changes in the prostate gland.

The last paper was entitled "Alcohol as an Anæsthetic," and was read by Dr. John E. Link, of Terre Haute, Ind.

After an experience of twenty years, the author recommended the use of whiskey as an anæsthetic. He advised the use of full proof whiskey at least two years old, giving from one to two ounces, repeated every three to five minutes, according to the rapidity of its absorption. The quantity given varies between sixteen and twenty-four ounces. The patient is then allowed half an hour to quiet down. If the desired effect is not produced, a few inspirations of chloroform are given. The two agents combined give better results than either alone. A number of cases in which this method was employed were reported.

Dr. Koser, of Williamsport, offered a resolution to be forwarded to Professor Billroth, congratulating him upon his recovery from his severe illness. Adopted.

After extending a vote of thanks to the President, the section adjourned *sine die*.

Section in Military and Naval Surgery and Medicine.

Dr. E. H. Gregory, of St. Louis, Mo., read the first paper, entitled "Amputation for Injury of Living Parts Never Necessary."

Dr. J. H. Gregory, of Omaha, Neb., read a paper on "The Superiority of the Bavarian Plaster of Paris Splints for Gun-shot and other Fractures of the Limbs," which gave the author's experience as surgeon during the late war.

Dr. R. F. Tobin, of Dublin, Ireland, sent a paper on "Some Remarks upon the Kind of Dressing Most Available for Gun-shot Fracture of the Lower Limbs on the Field in Connection with Transportation." This paper was read in the absence of its author, by Dr. Marston. The author advised fixing not only the injured limb, but the opposite one, and also the trunk.

Dr. Henry H. Smith was then presented by the section with a beautiful agate vase, accompanied with appropriate resolutions.

At the Afternoon Session, the first paper was read by Dr. E. Griswold, on "The Conditions on the Field which Justify Amputations in Gun-shot Wounds," in which the author stated that amputations are sometimes demanded when the exigencies of war will not permit of their performance. When a wound is beyond the reach of conservatism, the surgeon should amputate.

Section in Obstetrics.

The committee appointed to formulate resolutions in regard to uniformity in obstetrical nomenclature, made its report.

Following this report papers were read by Dr. S. Stringer, of Florida, on "A Rational Method of Relieving Asphyxia Neonatorum;" and by Dr. Ira E. Oatman, of San Francisco, Cal., on the "Treatment of Puerperal Eclampsia," in which he recommended *veratrum viride* as the best remedy.

At the Afternoon Session, Dr. H. O. Marcy, of Boston, Mass., read a comprehensive paper on the "Histology and Pathology of Reproduction," in which the writer tried to show that a destructive change effects the lining membrane of the uterus after conception.

Dr. E. Paul Sale, of Aberdeen, Miss., read a paper on "The Management of Pregnancy, with Reference to the Prevention of Post-partum Hemorrhage, in which he urged the importance of prophylaxis.

Dr. G. W. Jones, of Danville, Ill., read the next paper on "Dystocia from Rigidity of the Cervix and its Management."

Section in Diseases of Children.

Dr. A. B. Judson, of New York, Vice-President of the section, announced that the meeting would be devoted to Orthopædic Surgery.

The first paper was presented by Dr. Wm. E. Balkwil, of London, on "The Treatment of Congenital Club-foot, Demonstrated by the Exhibition of Apparatus."

Dr. Lewis A. Sayre read a paper on "The Necessity of Section of Contractured Tissues before Mechanical Treatment can be Effectual." The author defined a contracted tissue to be one that is shortened but yet is capable of being elongated, while a contracted tissue cannot be elongated.

A number of papers were then read by title. Following these, the section was closed by a few appropriate remarks from the President, Dr. J. Lewis Smith.

After this, preliminary steps were taken to form an American Pediatric Association.

Section in Ophthalmology.

Dr. E. Smith, of Detroit, Mich., read the first paper on the "Treatment of Abscesses and Ulcerations of the Cornea with Jequirity," and in which he reported very happy results following the use of the drug for this purpose.

Dr. D. S. Reynolds, of Louisville, Ky., read a paper on the "Necessity for Reform in the Manner of Designating Lenses," which was a purely technical paper.

Dr. E. Jackson, of Philadelphia, followed with the same character of paper, the title of which was "The Designation of Prisms by

the Minimum Deviation Instead of by the Refraction Angle."

Dr. G. S. Norton, of New York, followed with a paper on the "Relative Importance of Small Degrees of Astigmatism as a Cause of Headache and Asthenopia."

Dr. F. B. Tiffany then read a statistical paper on "Ametropia," in which he recorded the results of his examination of over two thousand school children in Kansas City, Mo. The paper gave occasion for a very interesting discussion.

Section in Dermatology and Syphilography.

Dr. A. R. Robinson read the first paper upon "Alopecia Areata, with Demonstration of Deep-seated Micro-Organisms." The author expressed the opinion that in this disease the hairs themselves were not diseased, and stated that he had found micro-organisms in the lymph spaces of the corium and subpapillary layer. He was inclined to regard them as causative. He has found chrysophanic acid trustworthy for treatment.

Section in Laryngology.

Dr. Carmalt Jones, of London, England, read a paper on "The Action of the Epiglottis in Swallowing," in which he expressed the opinion that the function of the epiglottis was not to act as a lid to close the larynx against the entrance of food as it is swallowed.

Dr. C. Slover Allen, of New York, then presented to the section a New Snare and Ecraseur.

At the Afternoon Session, Dr. C. M. Desvernine, Havana, Cuba, read a paper on "The Longitudinal Tension of the Vocal Cords, its Physiology and its Derangements."

The closing paper before this section was read by Dr. Joseph O'Dwyer on "Treatment of Chronic Stenosis of the Larynx and Trachea by Intubation." Dr. O'Dwyer's right to speak authoritatively upon this subject is well-known, and his remarks were listened to with close attention.

Section in Dental and Oral Surgery.

Dr. Starr gave an exhibition of the method of capping the exposed pulp of a tooth so as preserve its vitality.

Dr. W. J. Younger showed how to implant teeth.

Dr. F. Bush, of Berlin, Germany, read a paper on "The Comparative Pathology of the Teeth, with Special Reference to the Tusks of the Elephant."

Dr. E. Andrieu, Paris, France, read a paper on the "Sixth-year Molar," in which he expressed the opinion that it should be extracted.

In the discussion which followed, the opinion was general that such a view was obsolete, while Dr. Paul Dubois, of Paris, France, stated that French dentists did not do the operation.

Dr. J. S. Marshall, of Chicago, Ill., read a paper on "Operation for the Cure of a Persistent Facial Neuralgia of both Temporo-Maxillary Articulations, and Reflected Pain in the Right Brachial Plexus."

Dr. A. H. Thompson, of Topeka, Kansas, read the closing paper on the question, "Does Function Control the Evolution of Structure?"

Section in Climatology.

A number of papers were read, none of which were of general interest.

Section in Gynecology.

A number of interesting papers were presented before this section, but as they did not embody anything not already presented to the readers of the REPORTER, abstracts will not be reproduced.

Section in Anatomy.

Before this section Dr. A. H. P. Leuf read an instructive paper upon "The Proper Methods in the Study of Anatomy," in which he itemized defects in the present system of instruction, and indicated the direction in which improvements should be made.

FINAL SESSION, SATURDAY, SEPTEMBER 10.

At the General Meeting in the morning, the foreign delegates to the Congress offered resolutions embodying their thankful appreciation of the attentions shown them, and expressed particular appreciation of the services of Drs. Henry H. Smith, John B. Hamilton, A. Y. P. Garnett, Toner and Arnold.

In closing the last general meeting of the Congress, Dr. N. S. Davis thanked the foreign members in the name of the Medical Profession of the United States for their sympathy and assistance in the work of the Congress. He then declared the Ninth International Medical Congress closed.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Acute Polymyositis.

In a review of several cases of acute polymyositis, in the *Allgemeine med. Central-Zeitung* (July 23, 1887), there is the following account of a case of Wagner's. The patient was a woman, a cook by occupation, thirty-four years old, and suffering from chronic fibroid phthisis. During the latter part of June of last year, she was taken sick with pains in the back and loins. Subsequently there was stiffness and pain in the throat, neck and shoulders, and in the joints of the hands and legs. She was finally received into the Leipsic clinic on July 19, at which time, in addition to the troubles just mentioned, she exhibiting slight oedema of the backs of the hands, forearms and lower part of the thighs, which oedema increased and extended until in both arms the contour of the muscles could neither be seen nor felt, while motion was very difficult. On the extensor surfaces of both arms there was developed an erysipelatous redness with a remarkable indented border. The redness and swelling decreased and at the same time the moveability of the arms improved. The existing fever of 102° Wagner traced back to lung complications,

though physical examination of the chest did not show any progress in the process there. Therefore, the reviewer thinks, the attacks of dyspnoea are to be traced to an affection of the thoracic muscles, which were concerned in all these cases. The patient died in an attack of suffocation on August 29, after having had considerable difficulty in swallowing.

At the autopsy, characteristic myositic changes were found in all the voluntary muscles. In this case the diaphragm, the tongue, the muscles of the eye and the heart escaped; the spleen was of moderate size, and the brain, spinal cord and peripheral nerves showed no changes. Wagner endeavors to show the dependence of the symptoms in question upon progressive muscular atrophy; but according to the reviewer the three observations which have now been exhibited, to which a fourth made by Wagner twenty-four years ago might probably be added, make it seem beyond doubt that the disease must be separated from progressive muscular atrophy and must be regarded as an affection *sui generis* which lifts itself by distinctive marks out of the degenerative myopathies known to us.

"The appearance of the disease with fever, swelling of the spleen, and oedema," con-

cludes the reviewer, "the pronounced inflammatory nature of the muscular change, its preference for the muscles of the extremities, the progressive course of the disease to involvement of the muscles of deglutition and respiration, the escape of the eye-muscles and of the heart, tongue and diaphragm, the appearance of urticarial or erysipelatous eruptions which was observed in all three cases, the occurrence of death through attacks of suffocation and of pulmonary symptoms—all these features form the chief line of a picture of the disease whose further delineation must be relinquished to the future.

The author suggests for the disease the name "acute progressive polymyositis."

Effects of Hot Water Upon the Uterus.

As a result of his experiments upon rabbits, M. Milne Murray has arrived at the following conclusions:

1. The non-gravid uterus of the rabbit is subject to rhythmical contractions, one contraction every two minutes.

2. The introduction of water at a temperature of $105-110^{\circ}\text{F}$. produces an immediate state of tetany of the uterus lasting from five to thirty minutes.

3. The muscular contraction is accompanied by simultaneous contractions of the smaller vessels and the organ becomes exsanguine. The contraction of the vessels disappears gradually before the muscular spasm and is not followed by dilatation.

4. Water at $32-42^{\circ}\text{F}$. produces after 30-50 seconds a less energetic spasm than water at $105-110^{\circ}\text{F}$.

5. When the vascular constriction is followed by dilatation, the organ assumes a scarlet hue.

6. The spasm of the uterus is easily reproduced at short intervals by stimulating the uterus with hot water. It is not reproduced at a long interval by hot water.

7. A faradic current of short interruptions acts in the same way as hot water and produces tetany.

These results serve to explain the employment of irrigation in the treatment of uterine affections—*Revue Médicale*, June, 1887.

A Case of Total Extirpation of the Uterus and Nephrectomy in one Sitting, with Successful Result.

Schmidt's case is that of a woman forty-nine years old on whom extirpation of the uterus through the vagina was performed for carcinoma of the cervix. The posterior vaginal vault and the posterior vaginal wall

and right parametrium were infiltrated. In consequence of this the operation of Bardenheer was undertaken with great difficulty and haste. On investigating the extirpated uterus, it was discovered that a piece of the right ureter had been cut away. Bardenheer therefore decided upon the extirpation of the right kidney, which operation was executed at once by means of an incision opening from below. The patient recovered.

The author advises in similar cases to decide at once upon extirpation of that kidney whose ureter has been lost, and not first try by approximation of the stump of the uterus in the vaginal wound to obtain healing; otherwise it is easy, as the author has observed, for diphtheria and gangrene to arise from the urine dribbling over the vagina. The author believes that extirpation of the uterus is indicated when an accurate investigation has established the entire freedom of the surroundings of the uterus.—*Centralblatt f. d. med. Wissensch.*, July 30, 1887.

On the Drainage of Pelvic Abscesses by Trephining the Pubic Bone.

Rinne gives the following description of this process: Abscesses situated in the pelvis occasionally offer very unfavorable conditions for rational treatment, and thus, apart from the disease originating them which frequently is not influenced by treatment, the abscess cavity, for anatomical reasons, cannot be sufficiently cleared out and drained. The pus generally seeks its way outwards in the well-known typical manner. Surgery frequently aids these efforts of nature by early incisions, whereby the duration of the illness is considerably shortened; not unfrequently, however, it happens that the drainage of such pelvic abscesses can be carried out only very imperfectly; either the canal is too long and narrow, impeding the draining of the pus, or the pelvic cavity forms a kind of reservoir for the pus, the floor being more deeply placed than the drainage opening. This circumstance is often aggravated by the patients being forced to assume a permanent horizontal supine position. Psoas abscesses offer such conditions, especially those which open in the vicinity of Poupart's ligament; here the pus constantly stagnates, owing to the dorsal position of the patients. To improve the mechanical condition of the secretion, a drainage opening may be made into the deepest part of the abscess, through the pubic bone, and thus the pus may be carried out by the shortest route. Such drainage for pelvic abscesses by means of trephining the

pubic bone was first performed by Fischer (*Deutsche Zeitschrift für Chirurg.*, Band 13, p. 551), in 1880. No similar case has been described, but Rinne is informed that König and Madelung have repeatedly performed this operation, and a similar procedure has been carried out by Helferich. Fischer's case was that of a man 24 years of age, suffering from tubercular caries of the spine with an abscess, which was opened below Poupart's ligament; an opening was made through the pubic bone, which rendered drainage of the posterior part of the abscess cavity possible. The patient died of marasmus four and a half months later, but the operation had fulfilled all expectations; the enormous abscess cavity had contracted to a narrow fistulous channel, and no collection of pus was found in the pelvis. Rinne has twice performed trepanation of the pubic bone, both times successfully. These were cases where abscesses had developed in the pelvic cavity itself, and in the pelvic bones, they therefore offered better chances of cure than Fischer's case. But in both cases the discharge of pus had gone on for many years, and, notwithstanding repeated operations, it had been found impossible to arrest it. The relatively rapid cure after perforation of the pubic bone is therefore, without doubt, due to the favorable position for the discharge of pus, and the possibility of direct access to the affected portions of bone permitted by the operation. Rinne reports his two cases; only one of them will be abstracted here.

S., mechanic, aged 26, a weakly anæmic man, had suffered from coxitis in infancy, and recovered with ankylosis in good position. In the first years of the coxitis, the cotyloid cavity had perforated, producing a pelvic abscess, which became fistulous and remained so for fourteen years. The discharge of pus from the opening on the front of the thigh had varied considerably. In different hospitals the patient had been scraped, the fistula drained, but all to no purpose. Rinne proposed to chisel the pubic bone, which he did in October, 1882. First, he introduced a sound into the fistula, and marked the position of the abscess cavity in the hollow of the pubic bone. He advanced towards the cavity from without; the soft parts were cut through close above the great trochanter; the periosteum was peeled off, and a hole, the size of a shilling, made with the chisel in the pubic bone. A quantity of pus escaped and granulations protruded. The abscess cavity was carefully cleaned with the sharp spoon; the inner surface of the bone, which was bare, was also scraped. The bone

was nowhere necrotic or carious; it was indeed rather hard, and only a few vascular particles were separated by the spoon. The cavity was thoroughly washed out with salicylic acid solution, and a drainage tube inserted through the chisel opening into the abscess cavity. The subsequent course was without reaction. After three months, complete cure, with firm contracted cicatrices. The cure remains permanent. Both Rinne's cases were specially favorable for trephining. Such good results, of course, cannot be expected where the focus of pus formation is far from the pubic hollow, or where it is due to tubercular processes. Rinne considers this method as indicated in cases where the abscess has developed in the concavity of the os pubis itself, and in which evacuation and drainage at the usual places are insufficient. In congestive abscesses too, with stagnating secretions, and when the patients are bedridden, better mechanical conditions will be obtained for the drainage of the secretion after the pubic bone has been perforated.—*The Med. Chron.*, Aug. 1887.

Transfusion and Infusion.

To avoid the evils connected with transfusions of blood, as well as with infusions of common salt, Landerer recommends as an infusion a solution of seven-tenths per cent. salt with three to five per cent. sugar. The latter is recommended as a nutrient, and by reason of its high endosmotic ratio, in consequence of the quantity of sugar in the blood, the juices of the tissues strongly attract it; and finally the consistency of the solution is somewhat thicker and approaches more that of the blood, although it does not flow as easily as the salt solution through the capillaries, but forms more resistance in them, as is necessary for the maintenance of the normal blood pressure and circulation. The blood pressure rises upon the addition of sugar 30-40 per cent.—*Centralblatt f. d. med. Wissensch.*, July 23, 1887.

—For several years the inmates of the prison in New Orleans have been suffering from a peculiar disease frequently terminating in death. The disease was generally attributed to the damp condition of the prison. A physician of the State Board of Health made an examination, and stated that the sickness was caused by insufficient food. The rations consist of a cup of tea and a piece of bread in the morning, and soup during the day. The parish authorities have been directed to provide the prisoners with better meat and with vegetables occasionally.

BOOK REVIEWS.

The Student's Guide to Diseases of the Eye. By Edward Nettleship, F. R. C. S., Ophthalmic Surgeon to St. Thomas' Hospital, etc. Third American from the fourth English edition. With a chapter on Color Perception. By William Thomson, M. D., Professor of Ophthalmology in the Jefferson Medical College of Philadelphia. 8vo, pp. xx., 475. Philadelphia: Lea Brothers & Co., 1887. Price, \$2.00.

This excellent and reliable manual is addressed to students, but is equally well suited to the needs of practitioners, who will find in its pages much valuable instruction. The style of the author is pleasant, and the matter of his book is admirable. He discusses first the general principle of optics, which must be understood in order to study the eye rationally, and then passes on to a consideration of the normal eye. After this, he takes up the diseases and injuries of the eye, with the treatment suited to each, and gives a special chapter on operation. After this comes a most valuable section devoted to the relation of other diseases to diseases of the eye, and, finally one of the most useful parts of the book—an appendix, in which, in addition to a list of formulæ, there are helpful directions in regard to a number of matters which are simple enough to one who has been long practicing as a specialist, but which are calculated to puzzle the beginner not a little.

The book contains a chapter on color perception, by Prof. Thomson, of Philadelphia, who has made special studies in this subject, and has had the experience furnished by being in charge of the examination of the eyes of the *employees* of two of the most important railroads in America.

Druitt's Surgeon's Vade-Mecum. A Manual of Modern Surgery. Edited by Stanley Boyd, M. B., B. S., London, F. R. C. S. Eng., Assistant Surgeon and Pathologist to the Charing Cross Hospital, etc. Twelfth edition. Illustrated. Large 8vo, pp. xvi., 33-985. Philadelphia: Lea Brothers & Co., 1887.

Whoever is familiar with the compact book, which has long been known as "Druitt's Vade-Mecum," will be surprised to find this, its successor, grown into a large volume whose size makes the title seem ironical. The editor, in his preface, mentions with just appreciation the fact that more than 50,000 copies of the original have

been sold in England, and that "a copy was issued by the (United States) Government to each surgeon serving in the Federal army during the great civil war." But one reason for the latter step was the fact that the vade-mecum presented at that time an excellent manual on surgery in the most compact form which the market could produce. This merit of the book has been sacrificed in the present volume. In fact, the book has ceased altogether to be a vade-mecum, and is now a single-volume work on surgery, which must be estimated by comparing it with works of similar pretensions.

Estimated in this way, we find this twelfth edition to compare favorably with its competitors. It has been quite thoroughly modernized by the editor. This is very noticeable in the department of pathology, while in that of treatment we find the latest and most accepted methods, in the main, well described, as, for example, in surgery of the abdomen, and in the treatment of stone in the bladder. In some matters—as that of the treatment of tumours in the bladder—the recommendations are rather expressions of the opinion of the editor than of surgeons in general. In the section on aneurism we fail to find any reference to the excellent results to be obtained by the so-called "method of Antyllus."

There are other points in this volume which might be improved; but our space does not admit of our going into further details. On the whole, we think, as we have already remarked, that it compares very favorably with its competitors, and that it would be a valuable addition to any library.

In saying this, however, we would add that no American need feel that, if he wants a good work on surgery in one volume, he must buy a reprint of a revision of an old English manual. If his patriotism prompts him to do so, he can get a better book, by an American surgeon, from the very firm which publishes the one we have just been reviewing.

LITERARY NOTES.

THE fiction in the October number of *Scribner's Magazine* will include a strong story of life along the Arkansas river-bottoms by Octave Thanet. Its title is "The Mortgage on Jeffy." E. H. House's two-part Japanese story, "The Sacred Flame of Torin Ji," will be concluded. The next to the last installment of Harold Frederic's serial story will appear in this number.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

NO FEAR OF CHOLERA.

The report of a few cases of cholera occurring in a ship loaded with Italian immigrants, which arrived last week at New York, gives no concern to the United States health authorities, and need not alarm any sensible person. Surgeon-General Hamilton has already called attention to the fact that the circumstances connected with this case are not nearly so serious as they have been in cases occurring in former years, which were easily handled. For example: In November, 1848, the ship New York arrived at quarantine station, New York, from Havre, with eleven cases of cholera on board and seven deaths on the voyage. The number of cases increased to twenty the first day, and finally reached a total of sixty-three cases and twenty-nine deaths; but, winter setting in quite severely, the disease entirely subsided. Cholera did not again visit New York until 1866. The ship Atlanta arrived in November, 1865, with cholera aboard, but the dis-

ease did not break out until May, 1866. Two ships arrived in April of that year, one having had twenty-six deaths from cholera on her voyage, and the other thirty-one deaths. The passengers all brought an immense quantity of infected baggage, and the merchandise on the vessel was also doubtless more or less infected. It was at this time that the disease assumed its greatest mortality on Ward's and Blackwell's Islands. There were 172 deaths from cholera in the workhouse on the latter island, and the total number of deaths in New York was 1212. The ease with which cholera can be controlled was strikingly shown by the fact that the epidemic in the workhouse on Blackwell's Island lasted but nine days, and the outbreak began to decline from the day sanitary measures were instituted.

Further, we would call attention to the fact that cholera makes its greatest ravages among ignorant and superstitious populations. It is apt to find ready victims among such degraded people as the inhabitants of Naples, who recently forced one soldier to drink the carbolic acid he was using to disinfect the streets with, and killed another outright because he would not do the same thing.

In a country with such general intelligence as the United States, we do not believe the cholera will ever again obtain a foothold. So we say, let no one feel any alarm about what has just happened. We have no doubt that the New York health authorities will be fully able to cope with the circumstances, and that the city and country will be safe from any invasion of the cholera.

At the same time we think it well to call attention to, and to heartily endorse the suggestion of Surgeon-General Hamilton that the responsibility of nations in sending forth emigrants from infected districts ought not to be overlooked, and we agree with his hope that the time will come when it will be considered just as much an act of hostility on the part of a nation to neglect to take proper measures to prevent the spread of diseases to a friendly nation as it would be to shell and fire its seaports.

ARGUMENT AND RIDICULE.

At the last meeting of the Medical Society of the State of Pennsylvania several interesting papers were devoted to the subject of phthisis, among them two which discussed its treatment. The author of one of these papers dwelt upon the importance of securing proper nutrition for the patient in order to secure a cure. With careful nutrition as a keystone he presented the claims of various therapeutic methods, such as the inhalation of compressed air, medicated gases and sprays, the use of remedies to relieve the manifold symptoms, and the use of gaseous enemata by the method of Bergeon. Of the latter method of treatment he spoke as favorably as the short duration of its trial would possibly permit, he himself having had many patients who had been benefitted by it.

The writer of the other paper inveighed strongly and effectually against this plan of treatment. In sarcasm which would have been delicious had it been scientific, in invective which would have been destructive had it all been true, he cut right and left. Neither the originator of the method, the method itself, nor the many earnest scientific men who have honestly and patiently attempted to discover its merits were spared. Even the manufacturers of the apparatus, the merchants who sold it, and the persons who furnished the gas were scored.

We have called attention to the character of these two papers, not in order to express an opinion as to the views they advocated, but in order to contrast the manner of presenting these views. One of them was a temperate and scientific paper; the other was little better than a tirade. The author of the latter may have a correct estimate of Bergeon's method; but we think he has chosen an unfortunate way of presenting it. We believe it to be a mistake to introduce the arts of the forum into the halls of philosophy, and that such skill as was displayed in holding up to ridicule this particular matter, with the aid of voice and looks and gesture is dangerous to calm scientific conclusions.

For this reason we deprecate this style of argument, and would discountenance its employment in meetings where such serious matters as the preservation and restoration of health are under consideration. Here we need the man who has carefully and soberly studied his own experiences and those of others, and who can present the results of his study in plain and unimpassioned language, and not the man who can adorn a hasty and immature opinion with the seductive arts of rhetoric and oratory.

WOMAN'S VIEW OF THE CONJUGAL QUESTION.

We call attention to a letter published in our department for "Correspondence" upon the subject of the conjugal relation, as regarded from the stand-point of women. The subject is a very delicate one, and at the same time one of the utmost importance, and we recommend it to the thoughtful consideration of our readers.

We cannot suppose that the ideas suggested in the letter of our correspondent will prove novel to a large number of thinking men, and we imagine that, if they lead to any discussion we shall find that the peculiar conditions of our civilization are to a certain extent responsible for the hardships to which many women are subjected. To face the matter squarely, and to discuss it satisfactorily, will require a great deal of sense and no little courage; but we trust that the readers of the REPORTER are the very men and women to do it.

ABOUT CONTRIBUTED ARTICLES.

We publish in another place a letter from one who has been a welcome contributor to the columns of the REPORTER, and which indicates a frame of mind as creditable to him as it is agreeable to the editors. One of the most trying duties of an editor is to decline to publish an article which may be of interest, but which is not what editors call "available." It is a difficult and delicate duty to put a good article into the shape best suited to the requirements of a journal at any particular time. The men who can patiently endure having an article

declined are very few; those who submit gracefully to having an article cut down or trimmed up are not much more numerous, but both are among the dearest friends the editor has. Our contributors must understand that we receive more articles than we can possibly publish, and that we are compelled to select what seems the best material for all our readers. In doing this we often are forced to exclude what is both valuable and interesting, and those whose articles are not published may console themselves with the reflection that some of the best and most successful literary works ever published have been declined again and again by those who ought to have been better judges of their merit.

We trust that these remarks will not deter any of our readers from sending us contributions; but that they may lead them to do this in the admirable spirit of the correspondent whose letter we publish in this issue of the REPORTER.

ACKNOWLEDGEMENT.

A portion of the report of the proceedings of the Ninth International Medical Congress, which has appeared in this journal, has been abstracted from the advance sheets sent us through the courtesy of *The Medical Record*.

THE PHILADELPHIA MEDICAL TIMES.

Drs. Frank Woodbury and William F. Waugh have purchased the *Philadelphia Medical Times* and announce that they propose to give it a new dress and to introduce other improvements which they think will be acceptable to its readers.

—Prof. Da Costa presents the following as a strong point in the differential diagnosis of *chronic cerebral softening* and nervous exhaustion, or *neurasthenia*: In the latter, for a short period of, perhaps, a few minutes, the patient's mind will remain clear, and he is capable of mental effort, soon, however, to lapse again into his indifferent stupor. This alone, with the facts and history of the patient, will do much to establish a diagnosis when in doubt. In the latter, also, the headache is comparatively slight, while in the former it is a marked feature of the case. *Coll. and Clin. Record*, Aug., 1887.

NOTES AND COMMENTS.

Infanticide or Homicide.

The following case is reported in the *Munchener Medizinische Wochenschrift*: A physician was called to attend a tradesman's wife in her confinement. The presentation was a shoulder one with prolapse of an arm. After an ineffectual attempt to turn, the arm was cut off; then followed another ineffectual attempt to turn, after which the other arm was amputated and the lower jaw torn out. Even after this he did not succeed in extracting the child, and another practitioner was called in, who succeeded in delivering the woman. The first practitioner was cited before the Court, where the experts, professors, and practitioners expressed their unanimous opinion that the child had been killed by the injuries inflicted upon it; and that the contention of the physician, that the child was already dead before dismemberment, rested upon indications that were not scientifically justifiable. There were no just reasons for killing the child, and the practitioner had improperly failed to persist in his efforts to turn. After negligence had been incontestably proved by the opinion given, the defendant claimed that the case did not come under paragraph 222 of the German Strafgesetzbuch (negligent killing), but under paragraph 230 (negligent bodily wounding). The former referred to negligent homicide; the foetus, however, up to the time of dividing the cord, was a part of the mother's body, so that the case was only one of wounding. In opposition to this the Court ruled that the law recognized the vital existence of the foetus, and protected it as a human being, at an earlier period, viz., as soon as a part of the child became *visible* outside the vagina; paragraph 218 defined killing of the foetus *in utero* as fruit-killing (*Fruchttötung*); while paragraph 217 recognized the killing of a child *in* or immediately after birth as the killing of a human being (homicide). The Court, therefore, held the accused guilty of homicide by negligence, and condemned him to several years imprisonment. An appeal was not allowed.—*Med. Record*, Sept. 17, 1887.

The subject of brutality in the punishment of children has been creating intense feeling among physicians in England. Numerous examples of almost inhuman punishment have been brought to light.

CORRESPONDENCE.

A Woman's View of the Conjugal Question.

EDS. MED. AND SURG. REPORTER,

Sirs.—The increasing numbers of female physicians cannot fail to throw a certain new light upon some of the more obscure diseases and sufferings of women.

It was naturally to be expected that women suffering from some complaints should feel it easier to describe symptoms and feelings to one of their own sex, and the many complications involved in anticipated and accomplished maternity would equally find fuller expression in the same way. The result has been that, within the last ten years, much has been said of women's revolt against enforced maternity. Able pens have been enlisted in this cause, and a mother's right to limit and decide upon the number and succession of her offspring has been debated pro and con. There is, however, one side of the conjugal question which comes immediately under the notice of every practicing physician to which very little attention has been paid. It is this: How far does uncongenial or undesired coitus impair the general health of a woman; and in what degree does it influence the welfare, physical and mental, of the children born in wedlock?

It is an accepted fact that so-called "love children" are often endowed with physical and mental strength in excess of that of children born under the best "social" conditions. The offspring of illicit passion has nature on its side, while children born as the result of the mere indulgence of a habit, —often a matter of indifference, if not positive distaste, to one of the parents—come into the world handicapped. This will of course be readily acknowledged, and is in itself no light evil. But, beyond this, is there not, in the fact that men are accustomed to consider their desire a sufficient excuse for its indulgence in spite of apathy or at least unwillingness on the part of the wife, one cause, and a very serious one, of the nervous ailments of so many women?

Nature in her arrangement for the propagation of the race has endowed both sexes with natural passion, and obviously intends the gratification of the one to include the response of the other. Owing to man's greater physical strength and the violence of his passion, it almost invariably happens that after the birth of one or two children the mother passively accepts his attentions as a duty, often a most unpleasant one, and

looks upon the act of coitus as a mere sign of her submission as a wife. Incapable of feeling the same call without the courting and solicitation which the man no longer gives, she yields her person without her will, and becomes the mere machine through which her husband relieves his uneasiness. This, of itself, when we consider the frequency of most men's requirements, must have an injurious effect upon the nervous system; and when, as is too often the case, indifference amounts to absolute disgust and repulsion, it requires very little science to recognize a prolific source of suffering in this relationship.

Would it not be possible, by studying the facts elicited by female physicians from their patients, to acquire a knowledge which would throw light upon many of the most distressing internal complaints which proclaim themselves in the thousand nervous ailments of the weaker sex? Men, for the most part, sin in this relation from inadvertence rather than willful brutality, having been taught to consider marriage as the opportunity expressly provided for the "*lawful indulgence*" of passion, sanctified by church and society, and a wife as an orthodox and respectable exchange for a prostitute. Women, also from experience—the first passionate happiness of the honeymoon over—have also learned their lesson, and either feign pleasure, or accord simply endurance, because they fear that refusal will alienate a *man's affection*. What a satire on civilization is contained in those words! A man's affection and his passion are one; a woman's affection, and the acceptance of a passion no longer made pleasurable by solicitation, but claimed as a right, are his of conjugal right. A wider knowledge of the actual results upon body, mind and character of this state of things could not fail to teach a useful lesson, and help on the establishment of harmony between husband and wife.

May I, in excusing the length of my letter, suggest the consideration of this subject to your magazine? JANET E. RUNTZ REE.

About Contributions.

EDS. MED. AND SURG. REPORTER,

Sirs.—The inclosed is new to me and of course I thought it worthy of publication or I should not have sent it. However, if it is not specially new or interesting, give it a dose of waste-basket, and no harm is done. Or if the facts are worth stating, without publishing the article in full, simply use the facts as you please. Anything I may send,

you will do me a kindness by acting upon as the above would indicate. I find it does me good to write up a case even if it does not leave my office: as I believe one cannot write an article or report a case, but what he will receive a real benefit in the effort itself. It improves the memory and habituates one to getting his ideas into shape. So if I should send in something occasionally, my feelings will not be lacerated in the least should they not all appear, as the benefit to me is gained before they leave my office.

Yours fraternally, H. C. G.
Aletown, Sept. 17, 1887.

Correction.

EDS. MED. AND SURG. REPORTER:

Sirs:—In a recent issue of your journal appeared the following:

"An authority on canned goods reveals the interesting fact that most of the jellies in the market are made of apple parings and cores. Sometimes the stock is kept so long that it will not make jelly; then they make strained honey out of it."

I can affirm positively that there is not in this country a market for any such stuff as a syrup made of shop-worm apple cores. The nearest approach to honey in the line of adulteration *has been* glucose. The inventor of this method of adulteration was a man in New York, who subsequently went to England and practiced his methods there. The efforts of the journals devoted to bee-culture in this country, and the British Bee-keepers' Association in England, have driven glucose honey to the wall. More than all this, it is impossible to make out of second-hand apple parings, or any other kind of parings, a substance resembling pure honey. You cannot evaporate honey to a jelly, or water jelly to the consistancy of pure honey.

JOHN ASPINWALL.

Barrytown, N. Y., Sept. 10, 1887.

[We willingly publish the above authoritative correction of our error, and hope our readers will enjoy honey hereafter more than ever before.—EDS. REPORTER.]

NEWS AND MISCELLANY.

Cholera at New York.

A steamship from Marseilles and Naples, which arrived at New York on Sept. 22d, with nearly 600 passengers, had Asiatic cholera on board. Eight of her passengers died during the voyage, six of them from cholera, and on her arrival at quarantine four persons were sick of the disease. Sur-

geon-General Hamilton of the Marine Hospital Service says that New York has a quarantine board fully able to grapple with the exigency. Orders have been sent from Washington to the National quarantine stations at Cape Charles and Delaware Breakwater to detain all vessels coming from Italy, and report them to the Marine Hospital Bureau.

University Biological Expedition.

An expedition, sent out by the Biological Department of the University of Pennsylvania in June last, has just returned from the Bahamas, whither it went to collect specimens and to decide upon the suitability of these islands for the establishment of a permanent biological station, similar to the one at Naples, presided over by Anton Dohrn. The University has now a considerable fund at its disposal for this purpose, and hopes, within a few years, to have a station established, at which professors and advanced students would be enabled to pursue original investigations during their vacations. There are several such institutions in Europe. But there are none permanent in this country, although Johns Hopkins University has had such schools on Chesapeake Bay, in the Bahamas and elsewhere, temporarily, and, it is said, intends founding one permanently in the near future.

Dr. Charles S. Dolley, instructor in Biology in the University of Pennsylvania, was at the head of the party. M. J. Greenman and Charles F. Nassue, of the University; William S. Marshall, of Swarthmore; Arthur Lamb, of Johns Hopkins University, and Professor McMurrich, of Haverford College, were his associates.

The Union Medical Association.

The Union Medical Association, which includes physicians of Pennsylvania and Maryland, held their annual reunion at Mount Gretna Park, Pa., August 25th. About 300 physicians were present with their wives and families. Brooklyn, New York, Harford and Cecil counties, Maryland; Philadelphia, Dauphin, Lebanon, Lancaster, Adams and Cumberland counties, Pennsylvania, were represented. The doctors spent the day most enjoyably. Dr. O'Neill, the retiring President, delivered the annual address. Dr. S. J. Rouse, of York, who has faithfully served as Secretary for several years, was elected President. Dr. Bishop, of Harrisburg, was elected Secretary, and Dr. Alex. Craig, of Columbia, Pa., was re-appointed Chairman of the Executive Committee.

OBITUARY.

DR. RICHARD QUAIN.

Dr. Richard Quain, M. D., F.R.C.S., the well-known physician and writer on medical subjects, died in London, England, September 16, 1887. He was seventy-one years old. He was born at Mallow, in 1816, and became an articled pupil to a surgeon-apothecary at Limerick, and subsequently going to London at the age of twenty entered University College. Distinguishing himself in the classes, he was appointed house surgeon to the College hospital, and subsequently house physician to the same institution. He was elected a Fellow of University College in 1843. In 1846 he became a member of the Royal College of Physicians, and in 1851 was elected a Fellow of that College. His life since then was full of professional cares and honors. He was one of the founders of the Pathological Society and was a member of a great number of learned societies. Quain's "Dictionary of Medicine," published in 1882 (1800, pp. 8vo), is the standard work of its kind in the English language. He contributed numerous papers to the translations of societies, and to medical journals. Amongst the former was a monograph to the Royal Medico-Chirurgical Society, in which the true nature of fatty degeneration, especially in connection with the walls of the heart, was first described, and which largely influenced modern pathological doctrine.

DR. LUKE P. BLACKBURN, M. D.

Luke P. Blackburn, Ex-Governor of Kentucky, died at Frankfort, aged seventy-one years. He was born on June 16, 1816, in Woodford county, Ky. An absorbing love for the study of medicine, led him when seventeen to visit Europe. He remained in Paris studying medicine for a year, and then, returning to America, entered the Transylvania College at Lexington, from which he was graduated with honor in March, 1835.

Entering into the practice of his profession in Lexington, he met with much success. In autumn, cholera broke out near his old home. Dr. Blackburn went to the aid of the stricken and deserted villagers. His services were appreciated, for he was asked to settle in the town, and, doing so, his practice became very large.

Dr. Blackburn was made Health Officer of Natchez, Miss., and in the yellow fever epidemic which occurred in 1847, he did extraordinary work in relieving the suffering, as he did also in the epidemic which ravaged the South from 1853 to 1855. In 1854 he estab-

lished the first successful quarantine against the disease. Dr. Blackburn in 1847 also established a marine hospital on the Mississippi for river men.

Dr. Blackburn was one of the first to respond to the calls for medical help in the yellow fever epidemic of 1878, and his services during that year secured for him the Democratic nomination for the Governorship of Kentucky in 1879. Dr. Blackburn was twice married. His first wife was Miss Ella Guest Boswell, to whom he was married soon after leaving college and who died in 1855. His second wife was Miss Julia M. Churchill, of Kentucky, who survives him.

Correction.

The article on Mistletoe (REPORTER, Sept. 10th) should have been credited to Dr. R. L. Payne, Jr., whereas, the article is accredited to Dr. R. L. Payne, the writer's father, who several years ago used to contribute to the REPORTER.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from September 18, 1887, to September 24, 1887:

First Lieutenant Julian M. Cabell, Assistant Surgeon, relieved from duty in connection with the Annual Dept. Rifle Competition at Bellevue Rifle Range, Neb.; ordered for duty as Medical Officer at the "Rifle Camp for Team of Distinguished Marksmen," Bellevue Rifle Range. S. O. 89, Dept. Platte. Sept. 10, 1887.

Changes in the Medical Corps of the Navy for the week ending Sept. 24, 1887:

Surgeon H. P. Harvey, ordered to the U. S. steamship "Mohican."

Surgeon G. A. Cooke, detached from the "Mohican" and ordered home.

Medical Inspector C. J. Cleborne, promoted to Medical Director, Sept. 18, 1887.

Surgeon T. C. Walton, promoted to Medical Inspector, Sept. 18, 1887.

Passed Assistant Surgeon J. C. Boyd, promoted to Surgeon, Sept. 18, 1887.

Surgeon J. R. Tryon, ordered to Marine Rendezvous, N. Y., Oct. 1, 1887.

Assistant Surgeon J. G. Field, detached from Marine Rendezvous, N. Y., and ordered to the "Vermont."

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ending Sept. 24, 1887:

J. H. White, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon from Oct. 1, 1887. Sept. 19, 1887.

W. J. Pettus, Assistant Surgeon, to proceed to Savannah, Ga., for temporary duty, Sept. 20, 1887.

H. T. Goodman, Assistant Surgeon, appointed an Assistant Surgeon, Sept. 22, 1887; assigned to temporary duty at Norfolk, Va., Sept. 23, 1887.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

ON THE TREATMENT OF PAINFUL AFFECTIONS OF THE HEAD (CEPHALALGIA, MIGRAINE, TIC DOULEUREUX) BY ANTIPYRINE.

BY PROFESSOR GERMAIN SÉE.

Member of the Academy of Medicine and of the
Faculty of Medicine; Physician to the
Hôtel Dieu, Paris, France.

I. The history of *headaches* is largely a history of individual experience, for no painful affection is more common. Hard-working students are especially liable to headaches, but not necessarily those who violate all the laws of hygiene; many who live well and temperately, pursuing their studies in sunny, cheerful, well-ventilated apartments, and taking plenty of out-door exercise, are the victims of cephalalgia. What is the pathogeny of those grave headaches which are observed largely, though not exclusively, among bright, smart, though perhaps nervously constituted pupils, which interrupt hard brain work, which abate or go away during rest to return at the end of half an hour of close application, and which may end in compromising the education and even the future of children?

Four years ago, René Blache, and, almost at the same time, Zeller and Charcot, described under the name of *headaches of the growing period* those painful affections of the head which are so frequent in young

people between the ages of twelve and eighteen, *i. e.*, during the period of active growth, and which are of the nature of frontal pains that are very persistent and are aggravated by the least attempt at study. I have often witnessed this kind of brow-ache both in boys and girls, though more frequently in the former than in the latter.

A little attention will enable one to discriminate these frontal headaches from *migraine*, which is always a one-sided headache (*hemicrania*), accompanied with visual disorders, nausea, and vomiting; from facial neuralgia, which is always located in some sensory branch of the fifth nerve; lastly, from the anæmic or chlorotic headaches of childhood, which are recognized by the pallor of the tissues, by a hæmic murmur in the vessels of the neck and in the heart, and above all by the diminution in the hæmoglobin of the blood.

These headaches may appear, as the details of our cases show, in conditions of school or college life, where there has not been any over-taxing or forcing. In such cases it does no good to imperatively forbid all study; and to order out-door air and exercise, nerve tonics and sedatives (strychnine, quinine, bromides, etc.), and hydrotherapy, you will have gained nothing thereby, and it will need only a brief resumption of study to bring back all the former train of cephalic sufferings, to the chagrin of all concerned. What are you to do then? Suspend the education and compromise the future welfare of the child, or even put off all further training till nature shall have brought about a cure by terminating growth and the evils incident thereto? No

parent would ever consent to such a course as this, and I myself think it unnecessary from the following considerations:

After having observed numerous cases of headaches of the growing period, I was struck with their frequent coincidence with cardiac hypertrophy of the same origin and nature, such as I first described in 1885, and which is distinguished by an increase of the cardiac dullness and by respiratory embarrassment, by an apex murmur with the first sound of the heart, and sometimes by intermittences and palpitations.

In children from the age of seven to fifteen years the heart undergoes but moderate development, but from the age of fifteen to twenty (adolescence) it grows rapidly, sometimes exceeding the growth of the rest of the body; at other times its development seems to lag behind an enormous elongation of the frame. In headaches of cardiac origin, you will sometimes attain remarkable results by means of iodide of potassium given along with convallamarin or sparteine, two excellent cardiac medicaments which are tonics of that organ. The effects of the treatment confirm my theoretical view of these cases; these headaches are a part of the complex process of growth, and are connected with the physiological hypertrophy of the heart.

There is another class of headaches whose pathogeny is somewhat different. The subjects thereof are certain school children from eight to twelve years of age who have been overtaxed by too many studies at school, with too little time for recreation, or in preparing themselves for their examinations prior to promotion to higher courses of study. These are really cases of overstrain of the heart. At this time of life the growth of the heart is not commensurate with that of the rest of the body, and the nutritive shortcomings of the system seem to be reflected on the myocardium, which instead of hypertrophying, as in the case of the adolescent youngster, remains at a stand-still, or even becomes enfeebled, while the rest of the body is growing and emaciating. The heart is readily fatigued, and lacking self-reparative power undergoes dilatation, and this is especially likely to happen if undue physical exercise is imposed on the child, such as long walks of several miles at a time, or arduous gymnastic exercises; the brain work and the muscular work conspire to exhaust the forces of the child. I am, in fact, shy of recommending the gymnasium to primary school children.

The headaches then, coming on prior to maturity, are generally due to overtaking the

brain at school or college, or are incident to the growing period (cardiac headache), or, in the case of younger children, to general corporeal and cardiac debility. This complexity of causes renders somewhat difficult the matter of treatment.

In the presence of a problem so perplexing, I have of late directed my attention to the master symptom, the cerebral pain, which I endeavor to combat without attempting to reach the cause. To meet this indication, I have found nothing so useful as the regular, continuous employment of antipyrine, which has proved itself to be a unique remedy for the pains of which I have been speaking. I have before me notes of twelve cases which comprise adolescents from thirteen to nineteen years of age, of whom the greater part were suffering from cardiac headaches, and who had all been treated unsuccessfully by the ordinary methods. In all of these cases antipyrine administered in doses of fifteen grains three times a day, succeeded in calming the headaches at the end of two or three days, and causing them to disappear altogether at the end of six or eight weeks, the treatment being persevered with during this time.

Among these twelve cases pertaining to growing youths, I established an important distinction: seven out of twelve were hard working students, who were applying themselves with diligence and making preparation for their examinations prior to graduation or entering on more advanced courses; four of them had been obliged to suspend their studies for four or five months, and rest and tonics had not improved their condition, while under the use of antipyrine they were enabled to resume their studies. Two of these pupils were boarding at home where the conditions of hygiene were perfect, and were in the habit of taking abundant physical exercise; were in fact attendants at the gymnasium; they were none the less, however, victims of headaches. Another pupil was also vigorous of body and mind, but had suffered from headaches for several months. Another, aged 13 years, was rather dull intellectually; was endeavoring to make up for his deficiencies by hard study. Another student, aged 18 years, belonging to the polytechnic school, lost his rank in his class by not being able to apply himself to study more than half an hour at a time without suffering headache. He got well at the end of several days under antipyrine, and was able to make up his lost time and recover his rank. In all these cases the pathogeny was doubtless somewhat intricate; cerebral

fatigue entered as a factor, but active growth was going on at the same time, and in two of them there was an unusual development of the heart, a veritable hypertrophy. I have notes of another series of cases, five in number, all pupils of the same age, who could not properly be accused of overtaxing themselves; these youths were scholars of but moderate capacity, who studied intermittently and under compulsion, and with difficulty kept their rank in their classes; nevertheless they complained of the headache which presented the characteristics of the headaches of the growing period. I make exception from this number of one young man whom I suspected of secret vices and of untruthfulness, and who proved a more difficult patient than the others, although he eventually got well of his headaches.

Hence I have been led to believe that over-forcing the brain is seldom the sole cause of headaches in students; the true cause is the unequal physical development of the different parts of the body and especially of the internal organs. The headaches of the period of growth are often witnessed after a rapid increase of stature, and in these cases there generally exists an antecedent hypertrophy of the heart. Therefore if you have before you these headaches generally attributable to brain-tire, you are more likely to find that they are the headaches of the growing time, or cardiac headaches. I may add to this another category of headaches, those from fatigue or strain of the eye-muscles, which have been so thoroughly studied by my colleagues, Maurice Perrin, Jaral, and more recently Parinaud. Simple exercise of the eyes in reading suffices to bring on pain; this is especially the case in individuals affected with astigmatism or hypermetropia. These cephalic pains (headaches, migraines), may be much relieved or even cured by the use of suitable glasses and more careful management of the eyes.

Exception being made of this last category of cases, antipyrine, which is, in accordance with experimentation, the most powerful moderator of the excitability of the cerebro-spinal system and of the heart, proves itself to be specific in headaches of early life and adolescence.

II. We come now to the subject of *Migraine*. Migraine (hemicrania) should be distinguished from headache, trigeminal neuralgia, and myalgia of the epicranial muscles. Hemicrania is characterized by four cardinal groups of symptoms, which are generally associated and are sometimes accompanied by transient mental disturb-

ances; pain in the head, disorders of the facial and doubtless also of the intra-cranial circulation, perturbations of the sight, which when predominant constitute ophthalmic migraine; lastly, nausea and vomiting, which are frequent in the course of the paroxysm.

The pain in the head is the prime symptom; it generally occupies the orbital, supra-orbital and temporal, never the infra-orbital region; it is confined to one side and generally to one point; is continuous, with exacerbations provoked by the least movement, especially by severe muscular efforts (lifting, running, climbing); compression of the carotid on the painful side seems to increase the pain and the cerebral anæmia which always accompanies it. Circulatory or vasomotor troubles are never absent, though not always noticed; they manifest themselves by marked pallor of the face, with painful beatings of the temporals, retraction and injection of the globe of the eye, and dilatation of the pupils; at times the face is flushed and the pupils contracted. Study and all mental application are impossible; there is excitation of the special senses. This group of phenomena manifestly has its origin in the vaso-constrictor and vaso-dilator nerves.

The visual disturbances are very characteristic, and are sometimes so predominant as almost to leave the pain in the back-ground; scintillant scotomata are frequent, almost constant; there is often hemiopia, and even amaurosis, as has been shown by Charcot, Galezowski and Féré.

Lastly, there is no migraine without nausea, which is generally preceded and accompanied with anorexia, and sometimes by vomiting, though not necessarily associated with any symptoms of indigestion. The above description pertains to migraine in its typical form, which is easily distinguished from common headache, facial neuralgia or neuritis, epicranial myalgia, and specific periostitis.

Antipyrine is efficacious in all these painful affections, which are often due to special causes which one has no right to neglect. On the other hand, the causes of migraine are infinitely less varied and less known; we may conjecture the determining causes of the paroxysm, but we are ignorant of the pathogeny of migraine, as I shall endeavor to show.

Heredity is the only predisposing cause which has been clearly demonstrated; authorities are agreed as to the direct transmission of migraine from parents to children, and it is useless to hypotheate an indirect nervous inheritance originating in neurasthenia, hysteria, epilepsy or chorea in the

parents or ancestry. These family neuroses have no pathogenic relationship with migraine, which constitutes a neurosis by itself, never alternating with the other neuroses, still less with asthma, which is a pneumo-bulbar disease,¹ or angina pectoris, which is due to a lesion of the coronary arteries. Modern pathologists have made much of diathetic influences, and as the diatheses one after another have suffered subversion, there remains only arthritism—that is to say, gout and rheumatism. Arthritism, moreover, has been born of much that was once supposed to belong to it, and its very existence as a diathesis has been rendered somewhat nebulous. If we ask a definition of arthritism, we are told by some that it is “a retardation of nutrition;” by others, “an exaggerated nutrition;” by others still, “a functional disturbance of the nervous system,” *i. e.*, a neurosis, so that we do not seem to get much real light. As it has been demonstrated that gouty persons are not more subject to migraine than other non-gouty persons placed in similar hygienic circumstances, any attribution of this disease to a gouty origin seems meaningless and futile; nor do the results of treatment bear out any such attribution. Certainly, the alkaline and other anti-arthritic treatments have never cured or even helped migraine.

Thus far, then, the attempt to find a general or constitutional cause for migraine has failed, as well as every mode of treatment based on constitutional states. The question now comes up, whether there are any local affections or functional troubles capable of causing hemicrania by acting reflexly on the cerebro-spinal system, or on the vaso-motor nerves. Such a property has long been attributed to morbid states of the digestive organs, and it may seem a little rash to call in question the reality of gastric or dyspeptic migraines.

But just here not a little confusion has crept in. Just because there are no migraines without nausea and vomiting, some medical authorities have concluded that migraine has its starting point in the stomach. But individuals that thus suffer attacks are always victims of megrim, to which the gastric disturbance can only have the relationship of a predisposing cause; and it is just so with persons who testify to attacks coming on after a hearty meal, or after drinking freely of beer. On the other hand, are dyspeptics or individuals affected with organic diseases of the stomach—dilatation,

cancer, ulcer, gastritis—especially subject to migraine? Experience gives a decidedly negative answer to this question.

It cannot be shown that there are any morbid conditions of the stomach which are liable to provoke migraine. Nor do the remedies ordinarily given for dyspeptic and other disorders of the alimentary canal—pepsin, hydrochloric acid, alkalies, bitters, mineral waters, cholagogues, have any effect either in preventing or relieving attacks of hemicrania.

Therefore I can have little belief in the reflex nature of migraine; no more in fact, than in its diathetic or constitutional nature. Migraine, in fact, seems to be linked to a peculiar state of excitability of the cord, and especially of the vaso-motor centres, as the vascular conditions attending this neurosis prove, and as is shown by the results of treatment by bromides, caffeine, quinine, etc., which heretofore have been the best remedies in our possession, and whose tonic and sedative effect on the nervous centres principally implicated is well known. In short, I have long regarded migraine as an independent neurosis, very often hereditary, having little or no relation to vices of general nutrition, or morbid states of the digestive organs.

Starting from these data, and knowing the depressant effects of antipyrine on the excitability of the cerebro-spinal system, I have deemed it rational to subject my patients to the usage of this medicament, of whose calmative and analgesic properties I have now had such striking evidence. Out of 42 patients, the most of them ranged from 18 to 45 years, I count 6 young girls, 3 of whom are chlorotic; 12 married women, of whom 5 are neuropathic; 1 hysterical patient and 2 dyspeptics. Then come 12 young men who are hard students, but not given to excess of study, and 12 older persons, of whom 1 is gouty, 2 are suffering from renal calculi, 4 are rheumatic, 5 have heart disease, and 2 are in general good health. I add that none of my patients with the exception of the two women above mentioned, have any digestive troubles in the interval of their paroxysms; all are, however, victims of migraine, which with most of them is hereditary. All have taken antipyrine from the outset of their attacks; fifteen grains on waking in the morning, and fifteen grains an hour after. In all, without exception, after the second dose, or a little later, the paroxysm, which was wont to last all day, and even through the night, has been arrested, and the patients have been able to resume their studies, or their usual

¹ See *Maladies Simples du Poumon*, by Prof. Sée, Part I.

occupations. In every instance the remedy has been given in half a tumblerful of cold water just before or during the morning meal; the pain has usually disappeared in twenty or thirty minutes, the second dose acting only the part of preventive.

In the interval of the attacks, I have generally given no medicine, and yet in the case of most of my patients, the paroxysms became wider and wider apart; but such patients as were subject to more frequent attacks were enjoined to continue the antipyrine in one daily dose of fifteen grains. Out of these 42 cases I have noted but one where there was any intolerance on the part of the stomach, which, however, was not difficult to treat; in one case, however, there was vertigo, and in another such general distress followed by nervous excitation that I was obliged to suspend the use of the medicine. In all the other patients—38 out of 42—the success was immediate and complete, without any disturbance of the digestion, circulation, or functions of the brain.

III. *Facial neuralgia*.—To complete the series of painful affections of the head which have yielded to antipyrine, I must mention facial neuralgia. I have notes of seven cases of tic douloureux, all of a very grave kind, two of which were completely cured. One resisted antipyrine absolutely, while four have experienced marked amelioration, and appear to be in the way to recovery. These patients had been suffering from tic douloureux from twelve to eighteen years.

During this long and frightful period of suffering, these patients had never been able, without pain, to open their mouths, to speak, to chew their food, to swallow hot or cold liquids, to expose themselves to a current of air, or to enjoy the least respite, even under the influence of morphia or salicylate of soda. These four patients are enabled now, after two months of treatment, to enjoy that freedom from pain which they had not before known for years, and to live like the other members of the family. The treatment has consisted in the daily use of 5 grammes (75 grains) of antipyrine (fifteen grains every four hours, till the entire quantity was taken). I have also relied very much on the subcutaneous injections of antipyrine— $7\frac{1}{2}$ grains dissolved in the same weight of water, and the whole injected for one dose—but as these injections have sometimes been painful, I have lately modified my formula, as follows: I now dissolve my 50 centigrammes ($7\frac{1}{2}$ grains) of antipyrine in 1.50 gramme ($22\frac{1}{2}$ grains) of water, to

which, in order to enhance the effect, I sometimes add 1 centigramme ($\frac{1}{8}$ grain) of cocaine.

These injections act with surprising rapidity and energy. I now rely on these hypodermic injections in all inveterate cases, and during the painful paroxysms combining the hypodermic treatment with the internal administration of 5 grammes (75 grains) a day; the results in this most grave and most intractable of painful disorders have been unprecedentedly gratifying and surprising.

NOTES OF A CASE OF OPTIC ATROPHY AND TEMPORAL HEMI-ANOPSIA: SUSPECTED TUMOR OF THE PITUITARY BODY.

BY G. E. DE SCHWEINITZ, M. D.,

Ophthalmologist to the Orthopaedic Hospital and Infirmary for Nervous Diseases; Ophthalmologist to the Philadelphia Hospital.

I am induced to publish the notes of the following case on account of its similarity to one presented recently by Mr. Story, of Dublin, to the Ophthalmological Society of the United Kingdom. In the discussion which followed this presentation, references to other similar published cases were made, and in one of the instances quoted, a post mortem examination had revealed the presence of a tumor of the pituitary body.

Mary A., aged 15, presented herself for treatment with the following statement: As a child, she was subject to headaches, and often complained of dim vision, which would speedily disappear if she rested her eyes. For the past two years the failure of vision had been marked and unrelieved by any period or periods of improved sight. One year ago, while reading, the page became blank, and since that time reading has been impossible.

Examination of the Eyes.—R. E. sees hand move; L. E. 2° . Pupils large, 6.5 m. m. facing window, they reacted slowly to the changes of light and shade; anterior chambers natural; irides blue and alike in shade. The ophthalmoscope revealed in the right eye a small, oval optic nerve, entirely green and devoid of capillarity; out and below an absorbing pigment conus, and on the nasal side an area of choroiditis; lymph spaces along arteries full; hypermetropia, 2.5^{D} . In the left eye a small, oval optic nerve; nerve color green, but still partially capillary; vein and artery each full size; hypermetropia, 2^{D} .

The fields of vision were, as in the diagrams below, quite typical *temporal hemianopsia*. The field of the left eye was taken with a one centimeter square of white; that of the right eye with two candles, the flame of one of which was used for fixation, while that of the other was employed as the test object.

The patient came of healthy Scotch-Irish parentage, and with the exception of whooping cough and measles and the headaches before described, had had no noteworthy illnesses during early childhood. At birth three blue spots (venous naevi) were noted, one over the upper part of the left sternocleido-mastoid, one at the angle of the jaw, and one on the face in front of the ear. When the child was eight years old, the spot in front of the ear began to increase. At the time she was seen there was a purplish

her appetite good in spite of a very distressing nausea which often accompanied or followed an almost constant occipital headache. The urine was normal in quantity and color and contained no albumin nor sugar. The mental faculties were undisturbed, the knee-jerks normal and there was no anæsthesia, hyperæsthesia, nor paræsthesia, although she apparently appreciated the prick of a pin more readily on the left than on the right side. Often during the day-time this patient became very drowsy and slept for hours at a time; on awakening she was cheerful and lively. Her nights were usually good, although occasionally restless. Few days passed without these periods of drowsiness and sleep unless her mind was actively engaged. Excessive sweating, confined chiefly to the face, neck, hands and feet was a marked symptom. When last seen, five

FIG. 1.—Bitemporal hemianopsia. The outer tracings bound the limits of the normal fields for white; the inner tracings show the areas of the fields as they existed.

tumor, doughy and inelastic to the touch, extending from in front of the ear on a level with the zygoma, across the angle of the jaw and into the superior carotid triangle. The growth was ten centimeters in length and eight centimeters in breadth. The left auricle was of a mottled, reddish-purple color. When about ten years of age, this girl began to rapidly grow stout, so that at the time this examination was made, viz., in her sixteenth year, she presented a development unusual for a girl of her years. This growth had been symmetrical; there was no excessive development of the hands, feet or head; neither was there any deformity of the bones, nor indeed of any part except the presence of the tumor before described. Menstruation began in her fourteenth year, and she suffered severely from dysmenorrhœa. The tongue was clean, the bowels regular and

months after her original visit, no change in the ocular symptoms had taken place, except a distinct failure of sight in the left eye.

Treatment.—This has been in the main very unsatisfactory, as it of necessity must have been, except as far as the occipital headaches and nausea were concerned. A host of sedative and depresso-motor remedies had been tried without success, but these two symptoms yielded to successive fly-blisters placed over the occiput and along the nape of the neck. Although deprived of useful sight and apparently doomed to still further depreciation of vision, her health in other respects is well-nigh perfect.

Remarks.—The prominent symptoms of the case just described were optic atrophy most marked in the right eye; temporal hemianopsia; occipital headache, nausea and dysmenorrhœa; a tendency to grow stout

and periods of drowsiness. These symptoms were closely analogous to those present in the case reported by Mr. Story (*Lancet*, July 25, 1887, p. 1283). Dr. Hill Griffith and Dr. James Anderson referred to similar cases which they had seen and placed upon record. One symptom was present in the case which I have just detailed, provided this be an instance of tumor of the pituitary body, which I have not seen in other reported cases or supposed cases, viz.: excessive sweating, especially of the hands and feet. The pituitary body is composed of anterior and posterior lobes, the former of which are made up of a fibrous stroma, which contains numerous round and oval follicles filled with epithelial cells, while the latter are formed of a vascular connective tissue, in which collections of fat granules are found. Tumor formation in this body, while perhaps not of very frequent occurrence, has still been quite often noted. Cysts have been described and reported by Zenker (*Virch. Archiv.*, vol. 12) and Weichselbaum (*Ibid.*, vol. 75). A true adenoma of this region has been observed by Weigert (*Virch. Archiv.*, vol. 65); Weichselbaum (*loc. cit.*), and Ribbert (*Ibid.*, vol. 90). Klebs (*Viertelj. f. prakt. Heilk.*, 125) describes carcinoma and sarcoma. Weigert (*loc. cit.*) has seen gummata and Weichselbaum (*loc. cit.*) has recorded one instance of lipoma which grew from the posterior lobes of the pituitary body. Other instances of new growth of this region will be found in the Transactions of the Ophthalmological Society of the United Kingdom. There is a very curious state first described by M. Marie (*Lancet*, 1886, vol. 1, p. 1030) and named by him *acromegalie*, in which there is an acquired hypertrophy of the upper and lower extremities and of the head, while the forearms, arms and legs remain natural or grow but little. In addition, certain of the bones are misshapen, much as they are in the condition known as osteitis deformans. In a recent paper, Minkowski (*Berlin. Klin. Woch.*, 1887, No. 21) discusses this disease, and instances are there recorded in which enlargement of the pituitary body was found at the post-mortem. It seems then that evidences of overgrowth of tissue may be expected in the cases of tumor or hypertrophy of the hypophysis cerebri, whether this manifest itself merely in a tendency to grow stout or in the aggravated condition known as acromegaly. In the case just recorded no acquired hypertrophy or deformity of any tissue was present, except the tumor of the face, although there certainly was this tendency to grow stout. Inasmuch as the very presence of a tumor in sella tur-

cica in this case is merely a matter of surmise, it is perhaps idle to speculate upon what the nature of the growth might be. At the same time, it is not uninteresting to remember in this connection the tumor of the face and upper part of the neck. This bore the clinical characteristics of a subcutaneous venous nævus, inasmuch as it became distended when the patient stooped over, and again diminished in size when she assumed the erect posture. This growth began to enlarge in the patient's ninth year, at about which time, or a little later, the commencement of her present disabilities occurred. It is not unreasonable then to assume that at the same time an hypertrophy of the tissues of the pituitary body took place, an hypertrophy, moreover, akin in its pathological nature to that of the growth upon the face. Be this as it may, the symptoms in this case have been quite certainly produced by some form of pressure in the neighborhood of the optic chiasma, and from comparisons of other similar reported cases it is not unlikely that this pressure has been occasioned by an overgrowth of the tissues in the sella turcica.

GASTRIC DISTURBANCE FROM OVARIAN IRRITATION.

BY JNO. J. THOMAS, M. D., YOUNGSTOWN, O.

None will deny the influence which uterine or ovarian irritations or congestions are capable of exerting upon the functions of the stomach, and no phenomenon is more frequently pointed to in illustration of the relationship existing between these organs than the vomiting of pregnancy. The illustration is a well worn one, and is so frequently thrust forward that we are prone to overlook the fact that at any period of a woman's life, and during other than the pregnant condition, the most obstinate gastric derangement may be traced to the ovary or uterus. The following report of a case in point may prove of interest:

In the month of August, 1886, I was consulted by Mrs. T., aged 38, married, the mother of two children, the youngest aged 18 years. She complained principally of disturbances of the stomach, nausea and vomiting, diurnal and nocturnal. The patient was spare in flesh, as well as pale and anæmic in appearance; tongue clean and no epigastric tenderness. Finding her very reticent and indisposed to give a full and clear account of her symptoms, and happening to be in somewhat of a hurry at the time, I sent

her away with a prescription for good-sized doses of subnitrate of bismuth with a little pepsine to be taken after meals. In about two weeks the patient returned unimproved. This time she was given nitro-muriatic acid with nux vomica and gentian. I also advised counter irritation over the stomach and liver. In due time she reappeared, feeling somewhat worse. She was then placed upon small doses of Fowler's solution before and Warner's Pil Digestiva after meals. In course of two or three weeks she came again with the same old story of no improvement. By this time the feeble interest I at first took in the case was replaced by a determination to conquer both disease and patient. I questioned her closely, notwithstanding her strong disinclination to answer some of my questions, and insisted upon her submitting to an examination of the pelvic organs. With much reluctance I was permitted to make the discovery of a somewhat anteflexed uterus and an extremely tender left ovary. Here was an explanation why my previous treatment was of no avail. I immediately placed a fly blister over the ovary and began the administration of twenty grain doses of the bromide of sodium three times daily, and in less than twenty-four hours the stomach was at perfect rest. The patient slept undisturbed that night and thenceforth, whereas previously she vomited from once to three or four times every night. The bromide was used for a couple of months and finally discontinued. The only additional counter irritation applied was in the form of the ointment of the red iodide of mercury, a very limited number of applications sufficing to remove all remaining tenderness. The uterine displacement has been given due attention and the patient subjected to a course of tonic treatment with the effect of producing a very decided change for the better in the local and general condition. Not until last week was there any return of the nausea or vomiting, and then only in slight degree. Further counter irritation and a return to the bromide, will, I have no doubt, quickly cause the symptoms to vanish. Previous to the occasion of the third consultation, I had labored under a misunderstanding of the duration of a disorder that made this woman's life almost burdensome to her, and which had caused such interference with digestion and nutrition. Imagine my astonishment at being assured that the complaint was of *eighteen year's* duration, dating from a short period after the birth of her youngest child. At least half a dozen of the ablest and most experienced practitioners in this section had

prescribed for her infirmity—some of them more than once—none of them imagining the symptoms to be reflex in origin. I find no special fault with these gentlemen for committing once or oftener the error I myself fell into three times. In view of the light that now shines upon points once obscure in the etiology of disease, mistakes such as mine are utterly inexcusable. We are apt to grow careless and indifferent and to let slip facts and to lose hold of principles essential to our highest success as practitioners of medicine. Worst of all, those who confide in our skill suffer from our carelessness or indifference.

The books treat very inadequately of digestive disorders due to ovarian irritation. One of the most valuable contributions to the literature of the subject is that by Dr. J. Milner Fothergill, in *The American Journal of Obstetrics*, Jan., 1878. Much of the article is quoted from in the same author's work on indigestion and biliousness.

There is good reason to believe that the writer is not the only practitioner who has ever overlooked reflex influences in the causation of a gastric ailment. Perhaps you yourself, my more or less gentle reader, have more than once fallen into the same error. As regards the digestive organs, the signs of ovarian dyspepsia are negative. The tongue is apt to be clean, and there is no special tenderness in the epigastrium. The stomach takes offence at or rejects one article of diet as much as another. If to this state of affairs be added a decided sensitiveness in the region of one or both ovaries, you are justified in resorting to a blister. Internally, the bromides should be administered. There is no fact in therapeutics so conspicuous as the power of the bromine compounds in diminishing reflex excitability. In cases such as the one I have described the effect is sure and satisfactory. In many cases the vomiting of pregnancy may be greatly ameliorated by the use of one of the bromides. It is more than probable that an altered condition of the circulation within the ovaries is an important factor in the causation of the gastric disorders of the pregnant woman. Quite unaccountably, a possible influence from the ovaries has been almost entirely overlooked in most writings upon this subject. Dr. Bennett has shown the frequency of the association of an ulcerated condition of the neck of the womb with obstinate cases of the vomiting of pregnancy, and another author has noted the simultaneous occurrence of ulcerations of the neck and chronic congestion of the ovaries. Dr. W. Gill Wylie claims to almost invariably find either ulcerations of or an abnormally rigid or con-

stricted condition of the neck of the uterus, and states that upon the conditions being altered the vomiting ceases. Graily Hewitt finds in flexions or versions an explanation of the symptoms. Another observer insists upon spinal irritation or anæmia of the cord being at the root of the difficulty; and yet another, after canvassing the subject most thoroughly, declares all theories false and baseless, and finds refuge in "idiosyncrasy" as being an ample and satisfactory explanation of the causation of this always annoying and sometimes serious ailment. We are all aware of the influence of the cessation of the performance of the function of the ovaries at the "change of life," in producing all manner of nervous disturbance. The entire organism is often thrown altogether out of tune. The varying condition of the circulation within and about the ovaries so affect those branches of the sympathetic supplying the parts as to send forth a jarring influence from which any organ or tissue, however remote, may suffer. Is it probable then, that the sudden cessation of the function of menstruation, occurring as it does after impregnation of the uterus, is unfelt by the system in general?

I did not set out to prove that the vomiting of pregnancy was due to ovarian irritation or congestion, neither to advance a new method of treatment for this ailment; but I propose, as opportunity may occur, to interrogate the ovaries in all cases of irritability of the stomach occurring in the female, whether pregnant or not, where the symptoms are not obviously due to primary disorder of the stomach. If counter-irritants and sedatives prove inefficacious, they will but take rank with the methods and procedures which have from time to time been in vogue, and upon which various practitioners have placed some reliance, but which have signally failed to gain and retain the confidence of any considerable number of the profession.

RUPTURE OF THE HEART.

BY JOHN C. HOLMES, M.D., OF CRANBURY, N.J.

On account of the publication of many exaggerated newspaper reports, and because of the fact that I have received a number of letters of inquiry from physicians, I have concluded to give an account of the following case of ruptured heart which occurred in my own house.

Susan Orque, a colored woman, forty years old, had been a servant in my family

for seven years. During this time she had never lost a day from sickness, and never complained of any cardiac disease.

At 10 o'clock P. M., Aug. 22, 1887, she was found upon the floor of her room. She had done the usual Monday washing and had gone to her room, apparently perfectly well. I was absent from home, and Dr. Symmes, of this place, was sent for. He found her only partly conscious, beating her chest, pulse 100 and very weak, in a cold sweat and with convulsive movements of lower limbs. He administered sulphate of morphia and whiskey; after this the patient revived and became entirely conscious. She said indeed that she was *well*, without any pain, and wished to sleep. Dr. Symmes then left.

I returned home at 3.30 A. M. and found the woman asleep, pulse 80, respiration 20, and no indication of anything like heart disease. I again went to her room at 7 A. M. and found her awake and apparently doing well; she said she was "all right," excepting a slight headache. I was then called away, but at 10 A. M. I was sent for to come home, and was told that the woman had given a gasp and had died in a moment.

Under the circumstances I deemed a post mortem examination necessary, and accordingly sent for Dr. Rice, of New Brunswick, the County Physician, who made the autopsy 24 hours after death. The following conditions were found: rigor mortis well marked; a large amount of adipose tissue, two to three inches thick on abdomen; hypostatic congestion of lungs; rupture of right ventricle of heart, one inch long; pericardium full of blood; valves of heart sound; hypertrophy and dilatation of right side of heart; slight hypertrophy of left auricle; fatty degeneration of entire heart.

The woman had lived just 24 hours after she fell on the night of the 22d. Perhaps a clot had closed the rupture for this length of time, and perhaps the morphia and whiskey held her awhile.

It is singular that this woman had never complained of any cardiac disease, nor ever had any previous sickness.

Tanner mentions a case of rupture of the heart without any previous symptoms of disease. Ziemssen cites a case in which death did not take place until after eleven days.

—Scarlet Fever is epidemic in London. Eleven hundred and fifty three cases had been treated up to September 13, but the type of the disease appears to be mild.

SOCIETY REPORTS.

AMERICAN GYNECOLOGICAL
SOCIETY.

The Twelfth Annual Meeting of this Society was held in the Hall of the Academy of Medicine, New York, September 13th, 14th, and 15th, 1887.

WEDNESDAY, SEPTEMBER 14TH—SECOND
DAY—MORNING SESSION.

The President, in a few remarks, called attention to the death of Dr. John Scott, of San Francisco, Cal., and appointed Dr. Thomas Addis Emmet to prepare a memoir for the published Transactions.

DR. C. D. PALMER, of Cincinnati, O., read a paper on

**"The Therapeutic Value of Some Medicines
in the Treatment of Hemorrhagic
Conditions of the Uterus."**

The author referred to the fact that very few papers on the medicinal treatment of hemorrhagic affections of the uterus appeared in the eleven volumes of the Transactions of the Society. In hemorrhage from the uterus, it is important to remove the cause where this can be found. The object of the paper was to speak of the value of certain internal remedies, and their fields of utility.

No drug is more frequently used than ergot. This is beneficial in many cases, but may aggravate some. It is of service in chronic hyperæmia and in sub-involution. Its effects are less marked in nulliparæ than in multiparæ. In the treatment of uterine fibroids between the use of galvanism and of ergot, the field of laparo-hysterectomy must be a limited one. The hemorrhage from fungoid degeneration and from ovarian irritation is better met by other remedies. In some cases of pelvic peritonitis and pelvic cellulitis, the hemorrhage has been increased by the use of ergot.

Digitalis in appropriate cases is of service. It is reasonably reliable in uterine hemorrhage, due to cardiac trouble. In atonic conditions of the circulation, weak heart and low arterial tension, which tend to induce passive hyperæmia, digitalis may be used.

Cannabis indica has been the subject of diverse claims. The drug varies much in strength. It acts more especially on the nervous system. Its indications are imperfectly defined, and its effects uncertain.

Bromide of potassium is useful in certain hemorrhagic states. It is indicated where there is sexual excitement and ovarian con-

gestion and irritation. It is not so useful where hemorrhage is due to uterine irritation, although in some cases of fibroid tumor the author had found it more useful than ergot.

Arsenic is of service in uterine hemorrhage. It is not prompt in its action, but in appropriate cases it is effective. It acts as a tonic, stimulating all the functions, and especially those of the skin and mucous membrane. In chronic endometritis, with or without fungoid degeneration, a course of arsenic will be of material service. It is of value in the cure of young girls when menstruation appears too frequently and continues too long. In menorrhagia, at the time of the climacteric, it is of service, although its effect is less decided than in the former group of cases. Arsenic is a good remedy in menorrhagia of malarial origin.

Gallic acid is the best representative of the astringent class of remedies, and has been repeatedly tested in hemorrhage due to uterine atony. Its large dose, unpleasant taste and tendency to disorder digestion, limit its use.

It is the custom with many to use iron in the intermenstrual period. Iron tends to promote pelvic congestion and is almost universally injurious. Where there is menorrhagia due to hyperæmia, the muriated tincture of iron is beneficial.

Viburnum prunifolium, hydrastis canadensis and gossypium have been recommended. Dr. Garrigues has reported one hundred and thirty-nine cases of uterine hemorrhage from various affections in which he used gossypium with the result of relieving the hemorrhage in one hundred and twenty-five cases.

The last remedy referred to was hamamelis. If thoroughly tried, this is usually efficacious. The author has employed this drug with satisfactory results for six or eight years. It is not equally potent in all cases of uterine hemorrhage. For active, profuse hemorrhage, it is inferior to ergot; but for slight, long continued flux, where the blood is dark and venous, the hemorrhage being passive in character, it is the remedy *par-excellence*. This condition occurs in flabby sub-involute uteri after delivery or abortion, in some forms of chronic endometritis, in chronic retroversion and in some fibroids. The author has also used it with good effect in several cases of vesical hemorrhage from papilloma. The best preparation is the official fluid extract in doses of a few drops to two drachms. None of the remedies here mentioned were intended to supersede local medication where that was indicated.

DR. FORDYCE BARKER, of New York, said: I believe that every one of the remedies mentioned is of special value in certain cases, and success in treatment depends upon a careful selection of the cases. A drug useful in one class of cases may be inert or injurious in another class of cases. Arsenic is useful where the system is broken down and the patient is approaching the climacteric. It is useful not only from its tonic effect, but also from its effect in controlling vaso-motor disturbance. It is of special value if three or four days before each menstrual period, the patient is put on rather free doses of bromide of potassium. The arsenic is used only in the intermenstrual period.

Where the hemorrhage continues and is profuse, the most valuable remedy is the fluid extract by hydrastis, combined with fluid extract of hamamelis, half a drachm of each being given. Six or eight drops of tincture of nuxvomica may be added if there is an atonic condition.

I have used viburnum prunifolium largely in passive hemorrhage occurring at an early period of gestation, and in threatened abortion. I have found great benefit in cases toward the climacteric in the use of protiodide of mercury, with iron and a small quantity of opium.

There is another class of cases not specially alluded to, marked by profuse hemorrhage in very young girls, perhaps at the first menstrual period. In one of these cases where hemorrhage was exceedingly profuse, I relieved it by introducing a cone of alum wrapped in a piece of linen and passed it into the vagina. This restrained the hemorrhage. In other cases, I have relied on ergot and gallic acid, five drops of the former with five grains of the latter dissolved in mucilage.

DR. LLOYD ROBERTS, of Manchester, Eng., said: I have very little confidence in any drug except ergot in the treatment of uterine hemorrhage. The great point in the use of ergot is to get a good preparation. In cases of hemorrhage at the menopause, where the uterus is flabby, and in the case of young girls, the best results are obtained by giving it in the intermenstrual period. In malarial hemorrhage, I have found quinine better than arsenic. Gallic acid is the next best remedy to ergot. I think that the good effects of gallic acid are due to its local action. Except in cases where the hemorrhage is due to congestion of the ovaries, I should think that the use of bromide of potassium would be of little benefit.

DR. W. BALLS HANDLEY, of Melbourne,

said: I do not see how the remedies referred to are going to act in restraining hemorrhage. If their use is to be supplemented by operative measures, it is hard to say what does the good. Take a case of fibroid tumor: the growth is surrounded by muscular fibres. There does not seem to be the slightest impression in the minds of those who have spoken, that if these drugs can cause contraction of the muscles, they may cause the tumor to be forced towards the peritoneal cavity. I have given ergot and I cannot say that I have had the slightest benefit from its use. We must consider the natural history of these affections. Some fibroids increase very slowly, while others grow very rapidly. I have never seen the growth of one of these stopped by the use of ergot. I have thought that I have had some effect from the action of ergot locally applied, a piece of cotton being saturated with the fluid extract.

I would speak of one remedy, that is the tincture of the sesqui-chloride of iron. Some of these women are so anæmic that they go on bleeding simply because there is no power of contraction. In these cases the preparation referred to, in doses of half a drachm three times a day, is of value.

DR. J. A. S. GRANT (BEY), Cairo, Egypt, said: Two years ago I was called by a doctor to see a patient who had a tumor. Uterine hemorrhage recurred every ten days. I found a history of syphilis, and as hæmostatics had been thoroughly tried for months without effect, I decided to use mercury; stimulants and cinchona bark were also given. The hemorrhage ceased, and the tumor, which was as large as a child's head, gradually diminished in size, and in three months the woman was able to return to work.

DR. H. P. C. WILSON, of Baltimore, said: When I exclude cases of sub-mucous fibroids, cases of granulations and cases of polypi, the number of instances of uterine hemorrhage is very small. I have very little confidence in any remedy as a hæmostatic in these cases. The most trouble is experienced in young girls commencing menstruation. In these cases attention should be paid to the general health, the bowels should be regulated and exercise enjoined.

DR. JAMES R. CHADWICK, of Boston, said: I will speak of one remedy which I have found peculiarly efficacious, and that is Chian turpentine. I have used this in hemorrhages from all causes with surprising results. In one case a young lady had been losing blood for the greater part of two years. Dilatation had been done and curetting had been employed on several occasions. I could find no

definite cause for the bleeding. She was given six grains of Chian turpentine three times a day. Menstruation at once became regular and has remained regular. I think that ergot given between the flows is of more service than when given during the hemorrhage. During the flow I am in the habit of giving aromatic sulphuric acid.

DR. WM. L. REED, of Glasgow, said: I would merely refer to a drug which was formerly used. In certain cases where no apparent cause could be found, and where ordinary hæmostatics failed, I have found alum of service given in doses of twenty grains a day. When the immediate attack has ceased, I give sulphate of magnesia with sulphate of iron. I have great confidence in arsenic where there is disease of the endometrium. I prefer the iodide of arsenic.

THURSDAY, SEPTEMBER 15TH.

DR. ROBERT BATTEY read a paper on

Battey's Operation: Its Matured Results.

In August, 1872, the author performed his first operation for the removal of the functionally active ovaries for the relief of otherwise incurable troubles. Up to the present time there have been no statistics as to the ultimate effect of the operation. Reports have been given showing the immediate results, but none showing the results on the affection for which the operation was performed. All the cases reported in this paper have been traced carefully up to the present time. They were all the subjects of a complete Battey's operation, and had all been operated on a year, or longer. The name "Battey's operation" was retained, as it expresses the idea of the induction of the change of life artificially for the relief of disease, and this idea is included in none of the other terms, such as spaying, oöphorectomy, etc. Fifty-four cases were reported in the present paper. Of these, thirty-three were cured, eight were much improved, five were slightly improved, and eight were not at all improved. In fifty of these cases a complete menopause was induced, and in four there was a continued pseudo-menstruation. The detailed histories of a number of typical cases were then given. The following conclusions were then presented:

1. The change of life is the most important factor in securing the complete result of this operation.

2. In exceptional cases the cure almost at once follows the operation, but in the vast majority of cases the patient must pass through the ups and downs incident to the

change of life, before the restoration to health is complete.

3. The length of time required to pass through the nervous and physical perturbation attendant upon the change of life is variable. It may be one year, or it may be three or five years.

4. Of the cases operated on, a few were no doubt badly selected, and the proper selection of cases is a problem yet to be solved.

5. Patients who have become addicted to the habitual use of morphia, opium, chloral or alcohol, can not be restored to health until the pernicious habit is abandoned.

6. Cases which are the proper subjects of this operation, if allowed to suffer, eventually reach a stage where they become absolutely incurable by any operation.

7. In a number of cases the patients were in no wise benefited by the operation. In several of these the indications seemed clear and unmistakable.

8. In some cases, neuralgic pain remained. How much this was due to an unabsorbed ligature was a question to be considered.

9. A careful analysis of the cases seems to show that the removal of the tubes with the ovaries had no influence in the establishment of the menopause. The only effect of their removal being on the disease of the tubes themselves.

10. The operation is not an infallible one; the percentage of failures recorded is a notable one; but when it is remembered that the cases included are only those otherwise incurable, each case cured is a positive gain. A like percentage of cures in cases of cancer of the uterus, or of cancer of the breast, would be an achievement of the greatest magnitude.

In reply to the various questions asked of Dr. Battey, in the discussion which followed the reading of his paper, he said: I would say that I do not restrict the term Battey's operation to the removal of the ovaries. The removal of the ovaries is not a necessary constituent of the operation. Battey's operation consists in the induction of the menopause, no matter in what way it is brought about. The removal of the ovaries does not always bring about the menopause; the removal of the ovaries plus the tubes does not invariably cause the menopause; the removal of the ovaries, plus the tubes, plus the uterus does not always bring about the menopause. In my experience the ovaries are always diseased, but this is simply an accident of the operation. The operation is not done for the removal of diseased ovaries. Battey's operation is no

normal ovariectomy. I entirely repudiate that term. As a rule, I remove only the ovaries; but in a small proportion of cases, I remove the tubes, but only when the tube is the seat of positive disease, such as pyosalpinx or hydrosalpinx. The condition of the uterus varies in each case. I do not in-

sist upon visible changes in the ovary to justify its removal. I rest for my justification on the urgent necessities of the case and on the fact that nothing else effective has been proposed. I do not operate until all other measures have failed.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Placenta Prævia.

Dr. Nixon writes as follows to the *Med. Press and Circular*, August 24, 1887: Placenta prævia, complete or partial, is very seldom met with in midwifery practice. Dr. Ramsbottom states in his work that out of 48,996 cases of labor attended by him and his brothers in the Royal Maternity Charity from the year 1820 to 1850, they only met with 51 complete, and 31 partial, extrusions of the placenta.

The following is only the third I have met with during twenty-eight years' practice, and as it contains some points of interest for my younger brethren, perhaps you will give it space in your journal:

On March 23d, 1887, at 10.30 P.M., I received a note from a nurse in a neighboring district, requiring my attendance at once in a case, as she stated, of abortion. On my arrival I found my patient anæmic, almost pulseless, and a voice hardly above a whisper. Judging by her state that a recurrence of the hemorrhage would be fatal, I almost gave up all hopes. On inquiry I ascertained that she was seven months *enceinte*, and that this would be her tenth child, and that she had felt the life in it during the day. I gave her some brandy and ammonia, and waited until her syncopal state was removed before I proceeded to examine her. I found that the nurse had used the tampon, and applied cold applications which had lessened the hemorrhage, but still there was a good deal of weeping. Lubricating my hand and wrist with carbolized oil, I introduced my fingers, and was surprised to find the os nearly fully dilated, and a soft fleshy mass protruding. I at once diagnosed placenta prævia. On consideration, I came to the conclusion that the only chance for her life was immediate delivery, for if she had another attack of hemorrhage the case would be hopeless. Having given her a dose of ammonia and liq. ergotæ (Long's), I proceeded to introduce my left hand under the impression that I

would have no more difficulty in passing it through the thin edge attached to the uterus, than in my former cases, but I found myself very much mistaken. I could find no thin edge; there was nothing but a solid mass, which took me an hour to work my hand through. I at last succeeded in entering the uterus, and without much difficulty performed podalic version, there being little liq. amnii. I found a great tension on getting hold of one of the child's feet, but after a time I succeeded in bringing down the left leg.

I expected that the case would be immediately terminated, for I have found as a general rule from a quarter to half an hour is only required to terminate a case of turning. I used, as I always do, most gentle traction for the purpose of letting the breech pass as slowly as possible, with the object of making room for the head, so as to give the child a chance for its life.

I had the left leg just emerging from the orifice of the vagina, when to my horror it (the foot) came away in my hands, leaving the tibia and fibula bare. I had then to reintroduce my hands and arm, and under the circumstances found a greater difficulty in seizing on the right foot, but on bringing it down the foot parted in the same manner. I found it almost impossible to hold the two extremities together, or make the slightest effort for the propulsion of the child. Fearing laceration of the vagina from the exposed bones, I wrapped the extremities in a piece of calico and tied them tightly together. I then got hold of one of the knees, but all my efforts were useless in advancing the labor. I came to the opinion that evisceration was the only remaining resource, but at this stage my patient requested me to desist, as she wished to see the clergyman. I was not sorry, as I had been four hours on my knees, and giving her a dose of ergot in the hope of its producing pains, as the extremities had again receded, I retired until the clergyman left. On my returning, I was rejoiced to find that there were some slight pains, and I was enabled to place my finger

into the child's anus; after a time I succeeded in placing a blunt hook in place of my finger, which was a relief as it was cramped. I then, having more leverage, at length brought down the abdomen, and on its emerging I was graciously saluted with a number of jets of water, the child being in a state of decomposition, and must have been dead some days.

How the mother could imagine having felt it alive so recently is a mystery. The head was quite soft, the bones overlapping; the hands were on both sides of the occiput, and I expect the delay in the delivery was due to the elbows resting on the pelvis, as I have found the same to occur in other cases of version. The placenta came away without any trouble, but in all my experience I never saw one like it. It resembled a thick steak being two inches at the thinnest edge, and three in the middle; it had a most unhealthy color; the cord was a finger thick. There was a fleshy tumor contained and attached to the placenta, which appeared to me as a blighted conception. There was little or no hemorrhage, but a great deal of collapse on the termination of the labor, brandy, ammonia, and ergot, however, set my patient all right. The labor was not terminated until 5 o'clock the following morning. No bad effects followed, except debility, which nourishment removed, and the foetid lochia, which disinfecting injections cured. One thing is certain in this case, that if I had abided by the nurse's statement the patient would have died of blood-poisoning, as in a case to which I was called some time ago in consultation, a decomposed child was left too long *in utero*, and the result was the patient's death.

Extirpation of the Cricoid Cartilage for Enchondroma.

Böcker, of Berlin, reports in the *Centralblatt für die gesammte Therapie*, June, 1887, the case of a man, aged 62, on the cricoid cartilage of whose larynx there was a hard tumor as large as a hazel-nut. After performing tracheotomy, examination with the finger showed that the tumor was not movable, but embodied with the flat and also curved surfaces of the cricoid cartilage. The operator then introduced a tampon canula, and split the larynx to the hyoid bone, sawing through the thyroid cartilage, and extirpating the cricoid cartilage, leaving the arytenoid cartilages behind. The tumor proved to be an enchondroma, with the formation of spongy bone-substance in its interior. The patient recovered from the operation, but

was obliged to wear a permanent canula, as the vocal cords otherwise approximated on inspiration. Deglutition was unimpaired, and the patient was able, by stopping the aperture of the canula, or by using Brun's canula, to speak, although the voice was raw and hoarse in quality. At the end of a year the patient remained without any indications of a return.—*Therapeut. Gaz.*, July, 1887.

The Stimulating Action of Atropine.

With reference to the employment of atropine as an antidote in morphia poisoning, which was condemned by Lenhartz at the last meeting of the Society of Naturalists, Binz has instituted a number of experiments in which the strength of the breathing was measured by the quantity of expired air. From these it results that the respiration which is slowed by morphia is quickened by atropia, and besides, the general reflex excitability is increased. The convulsions which are observed in animals in morphia poisoning, do not come into the practical part of the question, for morphia in man is not a convulsive poison; most cases of death are due to direct paralysis.—*Centralblatt f. d. med. Wissensch.*, July 30, 1887.

Eczema at the Menopause.

M. Cheron recommends the following treatment:

1. Take at each meal, in colored water, a coffeespoonful of the following:

Arseniate of soda.....	gr. vij
Distilled water.....	3v

2. Take twice as a purgative:

Citrate of magnesia.....	3j-3jss
Syrup of gooseberries.....	3j
Water.....	q. s.

To be taken in two doses, at 15 minutes interval.
Diet: vegetable soup or weak tea, after the first stool.

3. Apply very gently every night this ointment:

White precipitate.....	gr. xv
Vaseline.....	3j
Essence of roses.....	ʒ ij

4. Every eight or ten days inject, subcutaneously, six to ten drops of

Nitrate of pilocarpine.....	gr. ij
Distilled water.....	3j

The latter is contra-indicated if there be disease of the heart or large arteries—*Canadian Practitioner*, September, 1887.

Unnatural Intercourse Between a Dog and a Man.

Brouardel, at a meeting of the Society of Legal Medicine (August 8th, 1887), reported the following observation of a physician of Orleans who desired to remain unnamed. This physician was called to a young servant, eighteen years old, who was said to have received a wound from a fall. The stable, where he was said to have fallen, had traces of blood upon the ground, but nothing was seen to explain the origin of the wound, which proceeded from the anus and was $\frac{1}{3}$ – $\frac{1}{2}$ an inch long. Finally the young man confessed that he had been in the habit of letting a hunting dog, of a fine fiery disposition, have intercourse with him. While he had been thus engaged, he was called into the house and sought to separate himself from the dog, but could not, and in the greatest despair, tore the penis of the animal out with all his might. In doing this the anus was torn just as the perineum is torn by the passage of the child's head through the vagina. —*Deutsche Medizinisch-Zeitung*, August 22d, 1887.

Diabetes.

At the Ninth International Medical Congress, Dr. Pavy, Senior Physician to Guy's Hospital, read a paper on Diabetes, of which the following is a brief abstract:

In this disease, which has always been regarded as an inscrutable one, there are still many points open for earnest study and patient investigation. The nature of the disease is that of faulty disposal and assimilation of food, especially of starch, dextrine, glucose and cane sugar, and each has an equal action, when ingested, in causing the condition of diabetes.

Normally the carbohydrates are disposed of in the portal vein, from whence they are carried to the liver and there assimilated. Experiments in which defibrinated blood or oxygen have been injected into the portal vein have been followed by marked evidences of sugar in the urine. Similar results have been produced in animals by forced respiration, thereby supersaturating the blood with oxygen. Vaso-motor paralysis of the hepatic vessels, by causing an excess of blood, prevents the proper deoxygenation of the blood, and similarly causes sugar to be present in the urine. This condition allows the carbohydrates to be converted into sugar and pass through into the general circulation.

In the celebrated experiments of Bernard, in puncturing the floor of the fourth ventricle, he also noticed a vaso-motor paralysis

of the hepatic vessels. It is noticeable that in those cases of vaso-motor paralysis of the chylopoëtic system where there is a red tongue the disease is more severe, undoubtedly owing to the fact that the paralysis has extended more generally throughout the circulatory system.

In health, there is only a faint trace of sugar in the blood and urine. The latter is always a reliable index as to the amount of sugar in the blood. In diabetes, the sugar reaches the blood directly, without going through the process of assimilation in the liver. In health, sugar is stopped before it enters into the general circulation, but in diabetes it is found in the blood directly in proportion to the quantity of carbohydrates taken. Sometimes even in health there is sugar in considerable quantity in the urine, in cases where there has been taken very large quantities of the carbohydrates, showing that there is a normal limit to the assimilative power of the liver, which, if exceeded, will result in a diabetic condition. The liver is a fat, rather than a sugar-producing organ, converting animal starch into sugar and then into fat. The liver is different from other organs in that it has small arteries and large veins. The contents of the portal vein should be in a decidedly venous condition, otherwise we will get sugar into the general circulation.

Diabetes is of neurotic origin, and it is well established that nervous conditions influence in a material manner the condition of the patient. The test for sugar in the urine should be a quantitative one.

In selecting urine for examination, it is necessary to procure both an evening and a morning specimen. It frequently occurs that sugar is only present directly after the taking into the body of carbohydrate foods. It is owing to the fact that specimens of the urine are procured at different times and under different conditions of diet that physicians differ so often in the diagnosis of diabetes. Among the various tests for sugar probably the most accurate is the copper test in the form of Fehling's solution. The great objection is that this solution will throw down a precipitate on boiling, which is very liable to mask the test. In order to obviate this I have had pellets made of the solid ingredients of this solution, in an anhydrous form, such as can be at any time dissolved in water for use.

It is well to note, in passing, that in diabetes we sometimes find albumin in the urine, and this is often present just in proportion as the patient improves or gets worse

A test for albumin, which has no known fallacy, is that with citric acid and the ferrocyanide of sodium. The objections to the nitric-acid test are that it may precipitate either uric acid or the oleo-resins. In the above test, if a pellet of citric acid is dissolved in the urine and boiled, we may then get a precipitate of uric acid, but upon the addition of the ferrocyanide of sodium the solution invariably clears up unless albumin be present.

In considering the disease itself, we find it has different grades and intensity, but diabetes may be said to exist when the assimilative power of the liver is below the ordinary. When a person first comes to have diabetes, as has been stated, it is through faulty assimilation; but as the disease progresses, the sugar is formed from the tissues themselves, as is proved by its constant presence when the patient is upon a strictly meat diet.

Age influences greatly the occurrence of the disease. Out of 1360 cases tabulated, forty-five per cent. occurred between forty and sixty years of age. Age also affects prognosis; young subjects rarely recover, the disease ordinarily terminating in two years. In older people the prognosis is more favorable, many recovering. One reason, possibly, for the tendency of children to do badly is that they take unsatisfactory care of themselves, while elderly persons are oppositely inclined.

Diabetes sometimes commences in a very mild form, and may exist a long time unrecognized. How do we know it is not recognized? It is said that bootblacks in hotels become expert in recognizing diabetics by the white stains on their shoes and clothing caused by coloring matter from their urine.

Then, too, diabetes runs in families in a very marked manner. One of the most striking instances of this was in a family which came under my observation, where the grandmother, the mother, and four out of her five children died of diabetes.

Recently I have found many cases beyond the middle period of life having pain in their limbs, which was formerly called neuralgia; they also have an irregular gait, somewhat ataxic. They sometimes feel as if they wanted to "gather themselves together," so that they may walk without giving their friends the impression that they have been taking too much. Again, they have the peculiar symptoms of pains in their extremities and "throughout the bones," which are much worse when they get warm in bed. This probably is, or analogous to, a peripheral neuritis.

In treating young subjects we must try merely to stay the disease; we cannot stop it. If we take away the sugar, the patient temporarily improves, and believes himself cured; but he is borne up only by false hopes.

In young subjects it seems to have a progressive character, not unlike progressive muscular atrophy, or of locomotor ataxia. For elderly patients we can do much. Appropriate diet is absolutely essential. Sweets, pastries, puddings and bread must be interdicted; while meat, eggs, poultry, butter and cheese may be taken. In regard to milk, it must be remembered that it contains lactic sugar, and, therefore, also cannot be taken.

In regard to bread, the gluten and almond breads are preferable, especially the latter, which contains fifty per cent. of fatty matter, and only seven per cent. or eight per cent. of carbohydrates. The medicinal agents which I give are opium, morphia, and codeia, which I think exert a restraining influence over the disease.

If the sugar disappears from the urine I commence to give my patient two ounces of bread daily; if, after a few weeks or months, I still find no sugar, I give him three ounces of bread, increasing in this manner until I give him six ounces, with which quantity he must remain content. If the bread causes the sugar to re-appear, it must not be taken.

We have seen that if there is sugar in the urine, it must be proportionately so in the general circulation. An excess of sugar in the blood predisposes to disease. The patient is then "ripe for anything wrong."

Dr. Pavy, on being asked by Dr. Herrick whether he considered the condition of the urine the objective point in the treatment, or if he aimed his treatment directly to the abnormal condition in the portal and hepatic circulation, replied that he looked upon the lessening of sugar as an evidence that the assimilative power for the carbohydrate was improved. The urine is an index of sugar plus the power within.—*N. Y. Med. Record*, September 17th, 1887.

The Operative Treatment of Serous and Purulent Pleuritic Exudations.

Most of this interesting paper by Immermann (*Deut. Med. Wochen.*), is taken up with the consideration of the question, "When is one justified in operating?" The question is answered under four heads; namely, (1) the duration of the illness, (2) the amount of the exudation, (3) the state of the temperature, (4) the character of the exudation. Leaving these, which are an-

swered much in the usual fashion, I shall simply try to describe his method of operation as shortly as possible. It is a system of drainage by a single tube acting as a siphon, and is, in fact, an incomplete form of Dr. Robertson's drainage system, described by him in this journal. An airtight india-rubber tube filled with aseptic fluid and clipped at the end, is introduced into the chest cavity by slipping it quickly through the lumen of a trocar, previously introduced and fitted with a stop-cock, momentarily opened to let the india-rubber tube pass in. The trocar is then drawn out of the chest, leaving the tube in. A clip is placed on the tube pretty close to the chest wall. The clip at the lower end of the tube is then removed and the trocar slipped off the end of the tube altogether. The tube is fixed by a bandage, and then the clip, still left near the chest wall, removed. The fluid in the pleural cavity flows gently out through the siphon, and the lung rises up and fills the vacuum as it forms. The fluid flows into a receptacle set on the floor—a bottle partly filled with disinfected water, and with its cork perforated by a glass tube, or better, with a double tube, one for discharging and one for sucking, etc., so as to dislodge the coagula that are apt to block the tube. As the discharge diminishes a small flask takes the place of the bottle, and the patient may walk about with this little flask in his pocket.

The tube may be used as an irrigator as well as an aspirator in cases where the discharge is offensive.

The results are excellent. One patient, aged 39, in less than two weeks after the operation was able to be up and sit or walk. There was then a scanty serous discharge which, in the course of the following month, got always less. The tube was gradually withdrawn from the chest and snipped off below, and a complete cure resulted.

In some cases the operation is useless, *e. g.*, when the chest walls are much sunken, the lung bound down by adhesions, or otherwise prevented from expanding, and when there are old firm coagula in the pleural cavity. This last mentioned hindrance is, however, often obviated by the clots breaking up and forming a sort of emulsion, which finally becomes a serous discharge.—*The Med. Chronicle*, August, 1887.

Mental Overwork in Schools.

Mental overwork and the bad hygienic condition of the schools of large cities have

aroused a great deal of interest and discussion among French physicians.

At a meeting of the Academy of Medicine at Paris, August 9, 1887, the subject received full consideration. Resolutions introduced by MM. Trélat and Hardy were discussed, and were referred to M. Brouardel to be embodied in one. The latter subsequently read the following resolutions:

1. The Academy of Medicine calls the attention of the public authorities to the necessity of modifying the present system in our schools so that it shall conform to hygienic laws and to the requirements of the physical development of the pupils.

2. It thinks that boarding schools and colleges should be established in the country; that a large open space ought to be reserved for recreation; that the class-rooms should be improved as regards light and air.

The course of study should be simplified. The Academy especially insists upon this point, that the time allotted to sleep should be lengthened for young children.

Moreover, for all the pupils, the time devoted to study and in the class-rooms, that is to say, the time during which the pupils are seated, should be reduced, and the time for recreation and exercise proportionately increased.

The Academy considers it absolutely necessary to submit all the pupils to daily exercise in physical training adapted to their age—such as walking, running, jumping, formations, calisthenics and gymnastics, fencing of all kinds, sports, etc.

The Academy voted nearly unanimously for the resolutions, with the exception of the last paragraph which, however, was carried against two or three dissenting votes.—*Le Concours Médical*, August 13, 1887.

BOOK REVIEWS.

Practical Lessons in Nursing.—Maturity, Infancy, Childhood. By Dr. John M. Keating, M.D., Visiting Obstetrician and Lecturer on Diseases of Women and Children, Philadelphia Hospital, Philadelphia, etc. 8vo., pp. 221. Philadelphia: J. B. Lippincott Co., 1887. Price, \$1.00.

Dr. Keating's book will be welcomed by those interested in the rearing of children, be they doctors, mothers or nurses. The manner in which the subjects are treated makes it one of the most valuable works of its kind with which we are familiar. Its suggestions—whether of advice or of warning—are so sensible, its directions are so plain and prac-

tical, and the line drawn between what parents and nurses may undertake and what they should refer to a physician is so clearly defined, that we do not hesitate to recommend it to our readers to be recommended by them to their patients.

Vaso-Renal Change versus Bright's Disease. By J. Milner Fothergill, M. D., Edin., Physician to the City of London Hospital for Diseases of the Chest, etc. 8vo, pp. 219. New York: G. P. Putnam's Sons, 1887. Price, \$2.50.

This book has the characteristics of most of Dr. Fothergill's works. It contains a valuable thought, not altogether novel, presented with great assurance of its correctness, and supported by citations of the author's observations and opinions, as well as those of other medical men. Its literary style is in keeping with the title, which is more sensational than we believe appropriate for a medical work. It is entertaining reading, although not entirely convincing, and is marred by certain errors of taste, such as the following allusion to an unsolicited conversation with a "lady friend of an old patient" (pages 145-146): "Now the manner in which these remarks were said, made all the difference between a very aggravated form of impudence and an interesting conversation devoid of offence; and making a strong impression on the lady's mind."

The whole account of this conversation is so entertaining that we regret we have not space to reproduce it. A more censurable breach of taste is to be found in the part of the book which the author playfully calls "L'Envoi," where he makes a comparison between himself and the Royal College of Physicians, which we regret to say is disparaging to the latter. The publisher's part of this book is admirably done: paper, printing, illustrations are beautiful.

Syphilis. By Jonathan Hutchinson, F.R.S., LL.D., Consulting Surgeon to the London Hospital, etc. Small, 8vo., pp. xii, 532. Philadelphia: Lea Brothers & Co.

This is one of a series of "Clinical Manuals for Practitioners and Students of Medicine," published in England and reprinted in this country. It is by no means the equal of some of the other members of the series, containing but a small amount of direct discussion of the subject and a large amount of padding in the way of "cases."

The book contains a number of interesting observations and valuable practical sug-

gestions in regard to syphilis. But, unfortunately, Mr. Hutchinson is one of the few eminent students of syphilis who still adhere to the theory of unicism, regarding the simple venereal ulcer (chancroid) as due to the same poison as the initial lesion of syphilis (hard chancre). This heresy taints all his teachings. A characteristic illustration of this may be seen in the book before us (page 99), where he gives this advice about the treatment of venereal sores: "The best plan is to give ether, and then very deliberately employ the Pacquelin's cautery in the most remorseless manner." If our readers wish to lose their patients and to shut themselves out from learning anything in regard to the true nature of syphilis, we advise them to follow this recommendation. If they wish to learn about syphilis and to treat it correctly, we would advise them to get any one of several excellent books on venereal diseases by American authorities.

A Practical Treatise on the Diseases of the Hair and Scalp. By George Thomas Jackson, M. D., Instructor in Dermatology in the New York Polyclinic, etc. 8vo, pp. 356. New York: E. B. Treat, 1887. Price, \$2.75.

The author of this work states, in his preface, that five years ago he was in need of a complete treatise upon the diseases of the hair, and, finding none of recent date, he began the studies which have resulted in the present volume. These studies have been very thorough, as may be seen from the very extensive bibliography with which the book ends, and also from the amount of information which is crowded into the volume. It would be impossible, with the space we can spare, to analyze its contents, and we content ourselves with recommending it to our readers as by far the most complete and satisfactory work on the subject with which we are acquainted.

LITERARY NOTES.

—The *Century* for October contains the usual array of interesting articles and admirably executed pictures. College men and physicians will be interested in a paper by Alexander Johnston on Football, in which the game is warmly and strongly advocated.

—The American edition of *The Illustrated London News* for September 24th is a very handsome and instructive number. "Ayoub Khan, the Exiled Afghan Prince," "The Burning of the New Theatre at Exeter," "The North Sea Trawling Fleet," are among the illustrations in this issue.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D., } EDITORS.
CHARLES W. DULLES, M. D., }

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

STUDIES IN THE PUBLIC SCHOOLS.

In another part of this number of the REPORTER we publish an abstract of an interesting paper on the subject of the strain to which many children are subjected by their school duties. This is a subject worthy of the attention of all men, and especially of medical men, who are concerned in everything which affects the health of the community. It has not been altogether neglected in this country, where many medical men are members of the board of directors who govern the schools. But it is a subject which deserves even more attention than it gets. In spite of the wise measures which have been adopted in many localities to arrange judiciously the duties of scholars, and to improve the conditions under which they must be performed, there is still room for improvement.

We are well aware that it is not easy to suggest a way to make this improvement. It is easier for one who is neither school-

director nor teacher, to say that scholars should not be forced along in large classes, without regard to their differing attainments and mental capacities; but it is not easy to say how this is to be avoided, especially in public schools. Still the effort to do something in this direction must not be abandoned. One way to do something will be to educate those who regulate such matters to the understanding that wisdom does not come with much knowledge, and that knowledge does not come with many studies. It is an error of our times to think that such studies as drawing, chemistry, languages, etc., are proper to all scholars. Experience shows that for the most of them these studies are a mere waste of time. We believe that it would be a good thing if the common schools confined their attention to the teaching of reading, writing and arithmetic, with history, geography and manual training, and—as an accomplishment—literature. If half the time wasted on useless studies—that is, useless as they have to be studied in the public schools—were devoted to teaching those who have been taught to read, what they can and ought to do with this attainment, we believe the next generation would call us blessed. No matter is more important, and none seems to receive less serious attention than this of directing the reading of the young; and it is a matter which ought not to be left for colleges, and high schools, and girl's seminaries, but which ought to be taken up wherever and whenever the art of reading is acquired.

If the studies in the public schools were limited to such branches as we have indicated, we believe it would not be difficult to arrange them in such a way that they would not be a burden to any scholar, and that they would permit of the division of schools into smaller, more individualized classes. It would also permit what we believe to be a second important desideratum, namely, the shortening of the school hours. We believe that it is detrimental to the degree of health to which each scholar might attain to be confined for five hours a day at study and recitation.

Up to the age of fourteen or fifteen years the young human animal should have the longest possible time for play. The school hours should be arranged so as to provide not more than four hours of book study, and an hour, or more, of play under the supervision of the teacher. This play should be so guided that it would furnish well-regulated exercise as well as amusement. As far as the studies are concerned we believe that the best possible preparation for active life in the United States would be a fair knowledge of the branches mentioned above, the most important of them being reading and literature—that is, training how to read. For we believe that a boy or girl who can read well, and who has been trained to a taste for good books and good newspapers, can after that accomplish anything he chooses in this country. A thousand instances in our history testify to this fact, and we believe that millions could be adduced to demonstrate that after years of study, as now arranged, a scholar may retain nothing of value except the knowledge how to read and to do the simplest ciphering.

THE TREATMENT OF HEART DISEASE.

Under the above head Dr. Thomas Oliver makes some valuable observations on various heart remedies, some new, some old, in the *Lancet* for July 30th.

In most forms of heart disease rest in bed is more or less a necessity, but this may be carried too far; in fact, physical exercise, gymnastics and massage have given some excellent results.

When the walls of the heart are feeble, and the propelling power is failing, there is no doubt as to the propriety of the cardiac tonics. First in importance is *digitalis*. This drug is indicated especially in failure of compensation. The cases in which digitalis acts most satisfactorily are those of mitral regurgitation, where the lesion has not been too long in existence, and where slight dilatation of the left ventricle is present. In aortic regurgitation, on the contrary, there is a general feeling that digi-

talis is contra-indicated. Dr. Oliver, however, does not share this feeling. He does not believe that, as some authorities teach, on lengthening the period of diastole greater reflux takes place into the left ventricle, and thus not only arterial and capillary anæmia, but also paralysis of the heart from over distention is favored. His experience has been that in aortic regurgitation, as in other forms of cardiac disease, the patient is likely to do well the nearer the beats of the heart are brought to the normal. Under digitalis, any slowing in the heart's action which may ensue is not only accompanied by improvement in the contraction of the cardiac muscle fibres, but also by increased arterial tension—which means not only the capillaries generally are better filled with blood, but also that the coronary arteries, too, are better supplied, and, consequently, that the heart is better nourished. The ill effects which Dr. Oliver has seen to follow the use of digitalis have been more gastric than cardiac. But as digitalis is a drug which raises arterial tension by causing contraction of the peripheral arterioles, and thus throws an additional burden on the heart, he would not use it in cases where he suspected fatty heart, or extreme dilatation of the left ventricle; nor would he consider its employment called for in any case of cardiac disease, no matter what the lesion in which arterial tension was already high.

In *convallaria* we have an excellent substitute for digitalis in the treatment of many cases of aortic regurgitation, and it is not contra-indicated in mitral regurgitation. Dr. Oliver has found it to relieve cardiac depression where digitalis had failed. He regards it as a pure cardiac tonic, acting directly on the heart by improving the tone of its fibre. It is generally well borne by the stomach.

Belladonna is not used in the treatment of heart disease as much as it deserves to be. In cases of mitral regurgitation, its efficiency is most marked. Excellent results have been obtained from belladonna in cases in which digitalis and other drugs caused violent sickness. Belladonna in such cases gives relief to the difficulty of breathing, to the

gastric irritability, and to the erethism of the endo-cardium.

Caffeine has given good results, particularly in mitral stenosis. Administered with convallaria, it raises arterial tension and increases diuresis.

Kola paste, in two drachm doses night and morning, acts as a prompt and powerful cardiac tonic and nutrient, and promotes diuresis. Cases of mitral and aortic regurgitation have derived much benefit from it, and dropsy has disappeared under its use. In the headache consequent on cardiac disease and contracted kidneys, it has also done good.

Next to digitalis, nay, in many respects superior to it, in Dr. Oliver's estimation, is *strophanthus*, which is one of the most powerful cardiac tonics we possess. A few doses of the tincture are generally sufficient to produce, in patients who are the subjects of aortic or mitral regurgitation, a feeling of well-being and comfort, followed by complete relief to difficulty in breathing. In functional cardiac irregularity its effects are quick and lasting, while in many cases of advanced mitral regurgitation the difficulty of breathing is soon relieved, the pulse improved, and the quantity of urine increased. Similar results have been obtained in the treatment of aortic regurgitation. Dr. Oliver recommends the tincture made from the seeds. Three minims of the ethereal tincture is a sufficient dose.

Sulphate of sparteine is one of the new cardiac remedies of which it is proper to speak highly. The dose is one to three grains. Under its use the weak heart has manifested a new vigor, arterial pressure has been raised, the coronary arteries have been better flushed, and the cardiac nutrition thereby improved; diuresis has increased, and dropsical effusions have disappeared. The action of this drug has seemed to Dr. Oliver surprisingly like that of digitalis.

Barium chloride raises arterial tension, and thus acts as a diuretic, with half-grain doses night and morning. Cases of aortic regurgitation have had their pulse-rate re-

duced, the pulse rendered fuller and firmer, and the amount of urine increased.

Venesection, Dr. Oliver thinks, has fallen too much into disuse. "In several of my cases of aortic and mitral regurgitation," he says, "I have not only succeeded in warding off impending death, but by removing blood from the veins, have placed the patient in the enjoyment of good health for months to come, repeating from time to time, as necessity arose, abstraction of blood from the arm."

In the treatment of angina pectoris, nothing has answered so well as the inhalation of a drop or two of *nitrite of amyl*. It often gives better results when given internally, beginning with two minims and increasing to ten, fifteen or twenty, combined with ten minims of sal volatile and ten of laudanum.

In the treatment of the insomnia of heart-disease, we have two reliable and safe drugs—*paraldehyde*, in doses of fifteen to thirty minims, and *urethran*, in doses of ten grains and upwards. Urethran is less unpleasant than paraldehyde, and produces calm and placid sleep where opium and its allies are unsafe, and where chloral cannot be given without running the risk of inducing cardiac failure.

—Dr. Frank H. Gardiner believes that decaying particles in the mouth as far back as the pharynx vault taint the breath exhaled very little, if at all. Mouth-breathers have a bad breath when the tonsils are enlarged, or when cheesy masses exist in the tonsillary mucous folds. Certain gastric derangements taint the breath only when gases are eructated through the mouth. The principal cause of bad breath is decomposition in the intestinal canal, the retention of faecal matters in the transverse and descending colon, and the absorption of gases into the circulation, finally exhaled by the lungs. Catarrh (nasal, pharyngeal, laryngeal, or bronchial) causes bad breath. Medicines or aliments which undergo chemical changes below the oesophagus may, by rapid absorption through the stomach-walls, or immediately below, give to the breath the characteristic odor. This bad breath is often a source of serious annoyance to patients, and the fact that it has more than a local cause is too often ignored by the physician who, therefore, fails to cure it.—*Med. Herald*, June, 1887.

FOREIGN CORRESPONDENCE.

GIESSEN, GERMANY, Aug. 25, 1887.

Probably the one great operation which will stand to the credit of ophthalmic surgery of the nineteenth century is the recent successful engrafting of the cornea of the rabbit in the cornea of the human subject by Prof. von Hippel, of Giessen.

This operation is of more than ordinary interest, for by it we are enabled to give useful vision in individuals who are now hopelessly blind. While the successful case was one in which the patient had a certain amount of vision, yet the results obtained prove that other individuals now without vision may be benefited. Your correspondent, who has recently been intensely interested in the success of this operation, determined to have a personal interview with Prof. Hippel, and see the patient upon whom the operation had been performed, as well as to elicit certain details in the *modus operandi* which are never given in an article descriptive of any operation. Therefore my visit to Giessen, an old university town, in the western part of Germany, was not without profit to myself, and I will, as well as I can, give your readers a brief outline of the result of that visit.

Giessen was made famous by the works of the chemist Liebig, and since his day has kept its reputation as a medical school on account of the corps of professors, which has added much to the keeping up of the reputation given it by the labors of the great chemist. The isolation and lack of amusement in this town make it a place where the student can find a paradise for study. There is nothing here to distract his attention. On this account the "privat-docents" are among the best qualified teachers in Germany, and many are the great men of the Empire who first drew their sustenance from the paps of this university.

The eye clinic of this institution is probably not the least famous of the many celebrated ones in Europe.

Dr. Guorg Brandeburg, first assistant, to whom I owe much for his kindness and courtesy, informs me that last year the eye clinic was visited by 2034 new patients, and from 450 to 500 major operations were here performed. The modified Graefe is the accepted operation for cataract enucleations by the German method, scissors and forceps alone being used to remove the eye-ball. Strabismus operations are done by the Graefe method, dilatation of strictures of the lachry-

mal canal with Bowman's probes, small size. Tattooing of the cornea is done at one sitting. Ulcers of the cornea are treated with ung. hydrarg. ox. flav., gr. $\frac{1}{2}$ to $\frac{3}{4}$, and atropia, and the actual cautery, probably the best and most efficient way of treating this disease. Buraw's operation for trichiasis is unknown, and when suggested for a case which was brought before us, was successfully applied. The after dressing of cataract patients is by bandages (gauze) stiffened by starch and sublimate, and dark rooms. The "rational method" has not yet reached this section of Germany. It was suggested, and in all probability the results will be given your readers at some future time by Dr. Brandeburg.

Prof. von Hippel has been giving his attention to corneal transplantation for the last ten years. He has experimented upon fowl, animal and man. These experiments are not numbered by five or six, but by hundreds, and it was only the outgrowth of this long line of experimentation that he was at last able to give to the profession the crown of his labors—a successful and wonderful operation. The patient is a young, healthy peasant girl, 19 years old, who suffered with a leucoma of the cornea of the right eye, obscuring vision to such an extent that qualitative perception of light only remained. The leucoma simplex obscured the central portion of the pupil, leaving, however, a circle of clear cornea at its outer margin, probably two mm. wide. The instrument devised by Prof. von Hippel for performing this operation is most ingenious. The trephine is driven by a clock-work and the cylinder is graduated so as to regulate its cutting depth in the cornea. The leucomatous cornea opposite the pupil was removed by this instrument. The eyelids were separated by an ophthalmostat, then under the influence of cocaine the trephine was placed on the cornea perpendicular to its plane, the cylinder so graduated as to cut a certain depth, 0.7 to 0.9; this cylinder is then put in motion by a spring clock motion much after the manner of a Dudgeon's sphygmograph; the hand simply steadies the instrument against the probe; after the circular incision is made comes the most important and delicate part of the operation, *i. e.*, the dissection of the leucomatous tissue from Descemet's membrane. This is done by grasping the inner lip of the incised tissue and with the greatest care and precision this tissue is removed down to the basement membrane lying in juxtaposition to Descemet's membrane. If, after the removal of

this circular piece of cornea, it is found that Descemet's membrane bulges forward through the circular opening, which in almost every case it does, a paracentesis of the anterior chamber is made at the corneo-scleral margin, relieving the intra ocular pressure.

The rabbit selected from which to obtain the graft is a young, healthy doe. The eye, which is thoroughly cocaineized, is drawn forward by an assistant who has inserted under the superior and inferior recti muscles two strabismus hooks; the eye-lids are kept open with an ophthalmostat; the drawing forward of the globe enables the trephine to be inserted and watched more accurately in its incision; the cut is made through cornea and *Descemet's membrane*; this graft is then inserted in the incision made in the patient; a fine probe running through the cylinder of the trephine is pushed downward, forcing the graft into place; after the removal of the trephine the upper eye-lid, which is drawn forward and downward, is pressed against the inlaid tissue, all being held firm by a pressure bandage, delicately adjusted, the patient of course lying on his back. After *three* days the bandage is removed, and the eye examined. If the graft is *in situ*, it will probably be somewhat hazy; if the edges have not turned upwards, a successful result may be prognosticated.

Prof. von Hippel will read an exhaustive paper on this subject, dealing with the details and giving his experience and his deductions in a paper before the Ophthalmological Society, which convenes, September 15th, at Heidelberg. I may add in conclusion that the second instrument made to perform this operation is now in possession of your correspondent.

L. WEBSTER FOX.

—Since the erection of the Brooklyn Bridge, a number of individuals have intentionally jumped from it into the river below, but, on August 1st, a young man who was assisting some workmen engaged in painting the iron-work accidentally fell from the bridge. He struck the water, one hundred and twenty feet below, chest first, and though he was unconscious when rescued, he soon recovered his senses under appropriate treatment. He was taken to the Chambers Street Hospital, where it was ascertained that he had received a fracture of the sternum, but beyond this and one or two slight bruises, he was apparently uninjured. According to the last accounts he was doing perfectly well. —*Boston M. and S. J.*, August 11th, 1887.

NOTES AND COMMENTS.

Selection of Health Resorts.

Dr. P. D. Rothwell, of Denver, Colorado, Prof. of Medical Chemistry and Climatology in the Gross Medical College, Denver, says that the physician who thoughtlessly writes a prescription for his patient, and sends him away with medicine that will only tax the eliminating powers of the system without in any way tending to eliminate the cause of his patient's trouble, is certainly guilty of a great wrong. The physician who in an off-hand manner advises his patient to go to such and such a health resort without a careful study of the climatic conditions of the health resort selected and a knowledge of the actions of such climatic conditions on the patient before him, is guilty of a greater wrong. To prescribe a proper climate for, say a consumptive, requires far more skill than to jot down the names of a few drugs to be compounded by a pharmacist and taken in certain doses. The former takes under consideration the sex of the patient, the age, education and tastes, companionship, pecuniary ability, the progress of the disease, susceptibility to æsthetic and psychical influences, and also the *purity, dryness, temperateness* and *brightness* of the atmosphere in the health resort to be selected.

The latter may not call forth any more mental effort than what is thus indicated: "This patient has a cough; I will give him one-eighth grain of morphine in a teaspoon-full of syrup of tolu and see how it works." The former requires a knowledge of life and its surroundings and sends the patient where constant factors are at work either for his weal or woe; the latter is often associated with the presumption of a quack and tends mostly to woe for the patient. The prescription calling for drugs invokes an agent to be used at certain intervals; the prescription calling for a change of climate calls to the person's aid factors that are always at work. The subject that should receive the greatest amount of study receives the least, and, as a consequence, many are sent to health resorts that would be better off at home, and many more are allowed to dally along with drugs at home that should be sent to places carefully selected.

Writers on health resorts are very often persons that have been benefited by residence in the localities praised, and may be excused for coloring the picture with the glow of returning vigor. Some write with

the characteristics peculiar to the newspaper correspondent employed by railroad corporations to encourage travel to portions of the country penetrated by their roads. Neither of these sources should be depended upon for useful information. Physicians of a scientific turn of mind, and, as a consequence, interested in the truth for truth's sake, should furnish the best information to those in need.

Colorado's fame as a health resort is widely known. Consumption is the trouble for which persons have come here and been benefitted. This article refers to that trouble only. Considerable has been written in reference to our climate and theories advanced in relation to its efficacy in the cure of consumption, some of which tend to mislead and make a mountain of explanation out of a mole hill of facts. The real pith of the matter is left out.

A most important factor to be remembered is the *diminished atmospheric pressure* owing to the altitude. Denver, for instance, is 5,200 feet above sea level; Colorado Springs, 6,080 feet, etc. Sending a patient from the level of the sea to either of these places is to a certain extent like putting him in a pneumatic cabinet from which some of the air has been exhausted. He will find the air thinner and of course will have to breathe oftener. To the patient whose lungs have not deteriorated too much, and to the one who has never developed the use of the lungs as they should be used, this will be a most useful indication. But to the one whose lungs are rapidly breaking down, whose reserve force is at a minimum, this extra work will hasten the process of dissolution; and it will do so before the unfortunate feels any benefits from the "balmy air and refreshing mountain zephyrs." The indications are plain. The diminished atmospheric pressure, too, encourages the blood to the surface of the body, tending to keep the skin—our everted lung—in better condition and at the same time relieving the congestion of internal organs—two essential points in the treatment of consumption.

The *purity* of the atmosphere of Colorado is largely owing to the absence of decaying vegetable matter, marshes, etc. Our soil is mostly a coarse, sandy loam into which moisture sinks rapidly, and upon which the native grasses dry and are preserved instead of decaying. Ozone, too, is freely developed in our mountain regions and thus adds to the stimulating effect of the atmosphere, and is opposed to the growth and multiplication of the comma bacillus.

Dryness of the atmosphere is almost essential to the improvement of the consumptive. Colorado atmosphere possesses this feature in a marked degree. Dryness does not favor the comma bacillus. Our climate is dry because the great mountain ranges attract the clouds where the moisture falls as rain or snow; in other places the nature of the soil where rain or snow falls is such as to prevent the moisture being long retained. Where the atmosphere is dry there cannot but be rapid changes of temperature. We have this, but there are so many benefits from the dryness that we are content to part with those that come from a more temperate atmosphere. A patient sent from the damp climate of Maine, say, cannot but be benefitted by the dry air bath into which genial climate invites him (other things being equal). To say that there are no winds in Colorado would be untrue. There are high winds sometimes. But dry air (comparatively) in motion, even though rapid, cannot reduce the temperature of the surface of the body as moist air in easy motion. This helps to preserve the temperateness of the atmosphere in winter and spring.

The amount of sunshine enjoyed in Colorado is very great. This might lead to excessive heat on the plains of our State, but for the fact that the great radiation caused by a few hot days is sure to cause currents of cool air from the mountains, that are not so very far away. During the very hottest of the recent days in Chicago and New York, when the hospitals were full with those that were prostrated by the heat, Denver was enjoying a temperature of 57° F. If the heat becomes oppressive a few hours' ride on the cars will take a person to cool mountain resorts, refreshing streams and sublime scenery.

To those unable to enjoy the luxury of hotels, and are able to work, light employment on ranches is available. This should not be lost sight of. Cases in which the disease has not made much progress would be far better off on a ranch with some light work than hanging around third-class hotels and sleeping in rooms four by ten.

There are many that come to Colorado depending entirely upon the climate, and do not call upon a physician here till they are compelled to. Such persons should be most carefully instructed by their physician in the East, before making such a change in their surroundings. That they are so instructed, I doubt; for they are sometimes found sleeping in just such rooms as above mentioned and daily expecting the Colorado climate to come into their rooms and heal them.

As stated before, to know whom to send here and when to send them requires more study than to write a prescription. Ours is a glorious climate—it has benefitted thousands in the past and has healing in store for millions in the future. Powerful for good, these rich blessings should not be prescribed without proper consideration of what the patient needs and how our climate is calculated to meet these needs.—*Denver Med. Times*, September, 1887.

Exophthalmia and Diplopia in Consequence of Empyema of the Sinus Frontalis.

Magnus (*Kl. Mon. f. Aug.*) reports a case of this nature, occurring in a woman, aged sixty-three. There was an elastic swelling at the upper and inner angle of the orbit on the right side, which extended far into the orbit, but did not project much beyond the orbital margin. There was no irritation of the lids or conjunctiva, and the motility and vision of the eye were normal. At times there was marked increase of the secretion from the right nostril. One month later the skin over the tumor became red and swollen, and after the use of hot applications fluctuation appeared and a small quantity of thin pus was let out. The inflammatory symptoms then rapidly subsided. Six months later the eye began to protrude downward, forward and outward, the exophthalmia rapidly increased, and the tumor itself became more prominent. A puncture of the latter let out a quantity of thin pus, and a diagnosis was then made of empyema of the frontal sinus. The mobility of the eye was much interfered with, but the vision and the fundus remained normal. An operation was then decided upon, and it consisted in chiseling away a portion of the anterior wall of the sinus until an opening as large as a mark-piece was made. About 60 grammes of pure pus were removed, and the finger could then be passed for about 7 ctm. directly backward. The thickened mucous membrane of the sinus was scraped away, and the cavity cleansed with carbolic acid. It was then tamponed with iodoform gauze. The diplopia ceased in three days, and the exophthalmia rapidly subsided, but the wound did not entirely close for about nine months.—*N. Y. Med. Journ.*, Aug. 13, 1887.

The Special Therapeutic Indications for the Use of Theine.

Thos. J. Mays, Professor (Adjunct) of Diseases of the Chest, Philadelphia Polyclinic, writes as follows: From its physiological

action, it is quite obvious that in theine we possess an agent which has the power of paralyzing sensation without affecting motion, and that it does this with a great degree of certainty and without any appreciable injury to any part of the body, even when administered in large doses. It now remains for clinical medicine to demonstrate and to establish how far this analgesic property can be utilized, and, with this purpose in view, the greater portion of the following pages will be devoted to the task of pointing out the special pathological conditions and to that of the citation of cases in which the drug is indicated.

In order to obtain the full effects of theine, it is not necessary to inject it deeper than immediately beneath the skin. Of deep injections I am not able to speak intelligently, since I was always satisfied with the results which are derived from superficial injections. Dr. Castle relates his own personal experience with one deep injection, in which the drug certainly exerted a marked influence on the brain, owing, probably, as has already been stated, to the fact that the whole dose found direct entrance into the circulation, and was at once carried to the great nervous centres.

Again, theine, as a rule, is surprisingly prompt in exerting its analgesic action. I have on a large number of occasions witnessed patients who had too much pain to move an arm, or who were too stiff to stand erect, swing their arms and straighten their bodies in less than five minutes after its introduction. It is not always so prompt, but this is probably due to the smallness of the dose. I have seen cases where no benefit had been derived from one-third of a grain, which, on the dose being doubled, improved at once. Therefore, when a single dose fails to act favorably, it is always advisable to increase, even if this has to be done to a large extent. I have repeatedly injected as much as two and one-half grains without experiencing anything except the best results. I would not hesitate to go even beyond this limit. To one patient who was suffering from the most intense neuralgia of both lumbo-sacral and left cervico-brachial plexuses, which was accompanied by sleeplessness, spasms of the muscles of both legs and of those of the left arm, I gave two and one-half grains of theine subcutaneously in four different localities along the spine, with instantaneous relief to the pain and the induction of sleep during the following night. This amount was injected daily for twenty-one days in succession, at the end of that time

he was almost entirely free from pain, improved in appetite and in sleep, and felt better in every way. In another case of locomotor ataxia I injected three grains of theine in different spots along the spine every other day, chiefly for the purpose of relieving the pain and contractions in the extremities, as well as the constriction around the base of the chest. It removed all these difficulties at once, and made the patient feel more comfortable than before. Another feature which recommends theine to favor is its prolonged influence. After pain has once been relieved by it, it is very rare to find the same returning inside of ten or twelve hours, and oftener not until twenty-four hours, and then, in all probability, not in its original intensity. I am referring now to obstinate cases of pain. Where the pain is more unstable, it is not rare to find that one or two injections relieve it permanently.

No prolonged irritation and no inflammation have ever been produced, during my experience, at the seat of its injection. It gives rise to some burning at first, which disappears in the course of a very few minutes, and is replaced by a marked area of anæsthesia. Most of the burning is undoubtedly due to the comparatively large amount of water which is necessary to dissolve a drug of a solubility as low as that of theine. When it is prepared with benzoate of soda its solubility is markedly increased, and I have therefore used it for more than a year according to the following formula:

R.	Theine,	
	Sodium benzoate.....	āā....3j
	Sodium chloride.....	gr. viij
	Distilled water.....	āāj

M. Sig.—For hypodermic use. Six minims equal one-half grain of theine.

Finally, in regard to the employment of a particular kind of theine I would say that everything which at present falls within the commercial description of both drugs is principally made up of theine; hence, very good clinical results are obtained from that which is found in the market, although it is very obvious from my experimental deductions in regard to the differential action of theine and caffeine, that the best results are obtained from the genuine article, which is now manufactured and furnished by Merck, of Darmstadt, Germany, and which I altogether employ at the present time.

In order to avoid annoyance and disappointment, it is highly important to constantly bear in mind the pathological conditions which only are amenable to the influence of theine. It must be borne in

mind, first of all, that its function is solely that of pain-relieving; and while it performs this office to perfect satisfaction, it also fails to give permanent relief to obstinate and protracted pain unless it is aided by remedies which tend to improve the nutritive state of the affected nerves or which are capable of removing the diatheses upon which the painful affections depend. A neglect of this simple rule frequently led to failures in my earlier employment of the drug.—*The Poly-clinic*, September, 1887.

Hay Fever.

From a study of forty two cases of hay fever, Roe (*New York Medical Journal*, Sept. 3, 1887), is led to the following conclusions:

1. That all cases of hay fever have their initiatory lesion in a diseased condition of the tissues of the nasal fossæ.

2. That the disease of these tissues induces, in the ganglionic centers connected with them, an abnormal activity, which is reflected to other tissues and organs.

3. That the sensitive areas in the nose are not confined to any particular locality, and that there are no zones in the nose that when irritated invariably produce the same manifestations.

4. That the direction in which the irritation is reflected is, like an electric current, always along the line of least resistance, and that from the same region it may be reflected in one direction at one time, and in the opposite direction at another time.

5. That the disease in the nose may produce disease in other portions of the respiratory tract, which may become independent centers of irritation.

6. That the affection distinctly recognized as hay fever is due to the effect of a local irritant, brought by the atmosphere in contact with the sensitive regions of the air-passages.

7. That the affection is not *per se* a neurotic disease, nor necessarily associated with a nervous temperament, although persons having a highly nervous temperament or a neurosis are much more susceptible to the influence of a local irritant.

8. That the neurotic condition which is often regraded as a cause of hay fever is itself often developed as the result of the local irritation.

9. That by carefully correcting all abnormal conditions found in the nasal or other portions of the respiratory passages, and the use of such systemic medication as may be required to remove any associated or consequent general derangement, we need not fail to cure hay fever.

CORRESPONDENCE.

EDS. MED. AND SURG. REPORTER:

Sirs:—Upon my return from my summer vacation, I find three numbers of the REPORTER awaiting me. Among the contents, I find a note on "Medical Epitaphs," by Dr. Keating.

If the Doctor will refer to Watson's Practice, edition 1858, page 846, he will find the same case recorded by Dr. Mead.

Dr. Bombaugh says that at the Old Men's Hospital, Norwich, England, may be seen the following: "In memory of Mrs. Phebe Crewe, who died May 28, 1817, aged 77 years, who, during 40 years practice as midwife in this city, brought into the world 9730 children."

Also at Wolstanton:

"Mrs. Ann Jennings.

Some have children, some have none;
Here lies the mother of twenty-one."

Also at Heydon:

"Here lieth the body of Wm. Strutton, of Paddington, buried May 18th, 1734, who had by his first wife 28 children, and by a second wife, 17; own father to 45, grandfather to 86, great-grandfather to 97, and great-great-grandfather to 23; in all 251."

Dr. Bombaugh also gives an illustrated epitaph from Williamsport, Pa.:

"Sacred to the memory of Henry Harris, born June 27, 1821, of Henry Harris and Jane his wife. Died on the 4th of May, 1837, by the kick of a colt in his bowels. Peaceable and quiet, a friend to his father and mother, and respected by all who knew him, and went to the world where horses don't kick, where sorrows and weeping is no more." Yours respectfully,

CHAS. H. COCKEY, M. D.

Baltimore, Md., September, 1887.

Consultation with Licensed Homœopaths.

EDS. MED. AND SURG. REPORTER:

Sirs:—I have a question I would like to see discussed by the readers of the REPORTER. In our State we have a law of registration which doctors must comply with before they can legally practice medicine and surgery in the State. By complying with this act they are legal practitioners within the meaning of the statutes. If the patient of a homœopath desires me to meet his physician in consultation, and I refuse to go because he is an irregular, *i. e.*, is not a subscriber to the code of ethics, has not the patient legal ground for an action against me for damages? Suppose that, as a fact, if I had met the doctor in

council, and changed the treatment, the patient would have been benefited thereby, and would have been a gainer. Now, if I deprive a patient of the benefit of whatever skill I may have because I refuse to recognize as a qualified practitioner one whom the statutes define as a legal practitioner, am I not legally liable for personal damages to the patient? I believe that, in a court of equity, a refusal to counsel with a legalized practitioner for no other reason than that the other doctor has not subscribed to, and reasonably complied with, our code of medical ethics, will leave us liable to actual and exemplary damages. Yours respectfully,

MILTON CHASE, M. D.

Otsego, Mich.

[We have taken legal advice on this question, and are informed that unless there is a special statute in any State, compelling a physician to consult, it is his natural right to decline to do so for any reason which appears to him to be sufficient.—EDS. REPORTER.]

The Conjugal Question—The Man's Side.

EDS. MED. AND SURG. REPORTER:

Sirs:—Dr. Rees's letter, in the REPORTER of October 1st, is interesting. But among what daughters of Eve can her lot be cast, that she tells such a chilly tale! My own limited experience is precisely the reverse; and as it tallies with that of men with much wider fields of observation, I feel sure there is some ground for saying a few words on the other side. Individuals are very differently endowed with the sexual appetite. There are frigid, sapless, Cassaubons, whose *uneasiness*, to use your correspondent's euphemism, reaches a climax only when the moon is full, or, who, like Tristram Shandy's father, attend to these little family concerns with the winding of the hall-clock on the first Sunday of each month. Mated to batrachians of this sort, there are women whose appetites are starved, and whose lives are rendered miserable. This is not alone the case where there is great discrepancy in years between husband and wife, but I have known of it in apparently well-consorted couples; and there have come to my professional knowledge two instances in which the woman sought, and found, elsewhere the gratification she could not obtain at home. To talk of a *healthy* woman, after the birth of one or two children, passively accepting her husband's attention as a duty, and often an unpleasant one, is to us men particularly naïve. It is more common in women than in men for the appetite to grow with what it feeds on; and

it may be safely said that in them passion does not reach its full development until later, often not before the fourth decade. My sympathy in this matter is entirely with the men, as I honestly think that in a large proportion of the cases—possibly the majority—they are the sufferers. There are men, of course, with huge, unbridled appetites—Solomons, for whom polygamy is the normal state; but such are as much the exception as are the women your correspondent describes.

Yours respectfully, TOBIAS SLOP.

Homeopathy.

EDS. MED. AND SURG. REPORTER :

Sirs :—A practitioner of the homœopathic faith, signing himself "*One of Them*," asks several questions in the August 13th number of the REPORTER, which, with your permission, I will endeavor to answer specifically first, and then in a more general manner. His questions are:

1st. "Has any system of medicine yet arrived at the stage in which it can claim to be acting purely on principles, and not at all empirically or experimentally?"

Answer. The homœopathic system makes this claim.

2d. "Supposing the principles of the old practice to be mainly right, does it follow that those of homœopathy are all wrong?"

Answer. Yes, if those of the homœopathic school are contrary to those of the "old practice," which, it is admitted, are mainly right.

3d. "If a homœopath, in some emergency of his patient, which in his judgment calls for a mechanical or immediate action, resorts to a cathartic, has he proved himself a traitor to his principles?"

Answer. Certainly he has, for such "resorts" are not in accord with "*similia similibus curantur*," a creed which should apply to every possible emergency.

Now, there should be reason and common sense in all things. Let us get down to the essence, to the merits, of the whole question. We of rational or progressive medicine, or, if you will, the "old school," regard that only as the true system of medicine, which is progressive, which evolves, which knows no *pathy*, *ic*, or *ism*, which adopts no exclusive creed. We aim simply to be physicians, following no system but truth. We accept and adopt anything and everything, no matter whence it comes, which will stand the test of common sense and scientific experiment, investigated by the usual ordinary principles of positive science. The reason we have not long ago accepted the doctrine

of homœopathy is because it is unreasonable, and unable to stand the tests we apply to every candidate for endorsement. It is true, and we confess it with humiliation, that in the early period of our history a most ponderous cloud of ignorance covered what is known as the "old school," but it was the *only* system which was *progressive*, which made any progress, which was anxious to progress, which did not, and would not, circumscribe itself within the confines of any such ridiculous creed as "*similia similibus curantur*," which may have suggested the well-known nursery rhyme:

"There was a man in our town, and he was wondrous wise;

He jumped into a bramble bush and scratched out both his eyes.

And when he saw his eyes were out, with all his might and main,

He jumped into another bush and scratched them in again."

We have made more genuine progress in the last thirty or forty years than was made in the preceding twenty centuries, not considering the discoveries of Harvey and of Jenner. There is not an important principle, fact or theory; not an important medical discovery; not an instrument of merit; nothing of sound, practical utility within the whole range and compass of the science and art of medicine and surgery, which did not have its birth and origin in the so-called "old-school." If homœopathy is increasing, as some claim that it is, it is certainly not because it is correct as a doctrine. Where it is in the ascendancy—if indeed there be such a place—it may be that the practitioners thereof practice *both* systems, as so many of them profess to do in this part of the country. I would like to ask "*one of them*" how a homœopathic adherent can conscientiously practice the old-school doctrine if he believes it to be wrong? And what his opinion is of the man who advertises that he practices both homœopathy and allopathy?

Yours respectfully,

H. V. SWERINGEN.

—DR. J. R. FORCE, of San Antonio, Texas, writes that he is "an allopath of the first water," but challenges those who criticise homœopathy to meet the argument that vaccination and Pasteur's practices of preventive and curative inoculation are homœopathic in principle. He also finds support of the homœopathic law in the fact that corrosive sublimate will cause inflammation of the bowels, and that Prof. Pepper recommends small doses of this salt for the treatment of the same condition. He also cites

the action of belladonna in health and in disease. His letter would indicate that he practices homœopathy at times with such success as to lead him to have some confidence in it.

—T. T. B., of Philadelphia, writes a letter in reply to that published in our issue of August 13, which is very similar to that of Dr. Schweringen, and in addition makes two good points: one is that the financial success of many homœopathic practitioners is no evidence of the correctness of their principles; the other is that a careful study of Hahnemann's work would probably cure an incipient leaning toward homœopathy in any candid and intelligent mind.

Close of the Discussion.

The details of our own opinion in regard to homœopathy have been pretty fully presented by our correspondents. The sum of them is that, as *a system*, it is contrary to every principle of scientific study or achievement, and that it is deservedly rejected by the great mass of honest and wise men who constitute the "old school," and deserted by the shrewd members of the very sect which flaunts its name. As a method of practice it cannot be denied to have a certain success, but this is in spite of the false theory upon which it is founded, and not because of it.

We also agree with our last correspondent, T. T. B., in recommending to any candid and intelligent mind a study of the doctrines of homœopathy as published in the writings of its founder. It is, to a certain extent, a waste of time to argue with one who has not learned in this way what homœopathy really is, and we think it would be an utter waste of time to argue with one who had this information and still believed in homœopathy.

—EDS. OF THE REPORTER.

—To detect turmeric in powdered drugs, the following method has been suggested: Upon a piece of filter-paper place a pinch of the substance suspected, and saturate with ether to extract the coloring-matter. When dry, add one drop of potassium hydrate to the stain, and, if turmeric be present, a red color, changing to brown, is produced, which is destroyed by acids. With care, less than 1 per cent. adulteration can be detected in this way. In testing rhubarb for turmeric, a pinch of borax and hydrochloric acid is added to the stain, and if turmeric is present a red stain is produced.

—*Chem. and Druggist*, July 30th, 1887.

NEWS AND MISCELLANY.

Dr. Quain Still Alive.

The death of Mr. Richard Quain has given rise to strange misapprehensions. Dr. Richard Quain, far better known in general society, and still we are glad to say in good health and in active pursuit of his professional duties, has naturally been confounded with his deceased cousin. Hence, Mrs. Quain has received numerous letters of condolence; friends have called at Harley Street to ask when the funeral is to take place, and others have been startled, most agreeably so, of course, at seeing the genial physician walking about in full health and spirits after his reported decease. The confusion, sufficiently great on account of the identity of Christian as well as surnames, is increased by the tendency of the general public to call every member of the profession "Doctor," so that we hear at the clubs that "not Dr. Quain, but the other Dr. Quain is dead." "Mr." Quain was the great writer on anatomical subjects; "Dr." Quain is the author of the *Dictionary of Medicine*.—*Brit. Med. Journal*, September 24th, 1887.

Butterine or Margarine.

The House of Lords determined on Friday evening last to retain the name of margarine as a right and proper designation for a certain substitute for butter, and which has for several years been selling under the illusory name of butterine. A large trade has been done among the poorer classes in this sophistication, and although it may be wholesome and nutritious, it is a fraud upon the public to sell it as butter, and which is done to a large extent in all the more populous neighborhoods. More than one noble lord argued that because a trade of several millions a year was now carried on in the manufacture of this article it would be wrong to interfere with it in any way. But this line of argument will seem to most of us to cut both ways, as the greater trade the greater the fraud practiced on those among the community who are unable to distinguish between the spurious and genuine article; and the large sale of which greatly interferes with that of the genuine article, butter—the trade mark, in fact, of the dairy industry, and it is only just to this industry that it should be protected against infringement of its trade mark. It should no more be in the power of the cheesemonger to supply his customers with a "bogus butter" than it is that of the

publican to sell sugar and water for beer as brewed and sent to him by the brewer. It was argued that margarine is a false name, but if it be so, then we reply that butterine is decidedly falser. This imitation of butter has, no doubt, the substance oleomargarine for its basis. It is subjected to certain chemical and mechanical processes, it is colored and made pleasant to the eye and to the taste, but still it is not butter, and has no right to hang on its skirts as if it were the genuine article, and after all is said about it, it is simply ox-fat, and should be labelled imitation butter, and thus made to stand on its own merits. There is no doubt that the use of a title for a substance which is wholly different from butter is an act of injustice, since it must, more or less, injuriously interfere with an important branch of industry. On this ground alone the farmers are fairly entitled to protection, while the housewives of the working classes have a right to know that butterine is not butter.—*Med. Press and Circular*, Aug. 10, 1887.

The Influence of Tobacco on Health.

In the course of upwards of a thousand observations on the influence of tobacco on the health of workmen, women, and children engaged in tobacco manufactories, Madame Walitzkaja found that the inhalation of an atmosphere laden with tobacco dust determined nervous troubles of a particular type. Dilatation of the pupils was frequent, together with cardiac enervation, exaggeration of the reflexes, tremulousness of the hands, and dyspnoea. The work people are subject to headache and fainting fits, gastralgia, etc. After the nervous system the respiratory function is that most commonly interfered with, but phthisis is not frequent. Experiments on animals proved these symptoms to be due to the tobacco and not to other causes.—*Ex.*

Driven Crazy by Inhaling Acid Fumes.

Dr. Howard A. Lever, Health Officer of the town of Flushing, L. I., has filed his report on several cases of insanity which have recently caused much trouble in College Point, L. I. Two of the men, Montz Beyer and Charles Schwartinger, are raving maniacs in Poughkeepsia Asylum. It was alleged that the fumes of the acids used on the preparations of rubber in the works where the men worked had affected their brains. In his report Dr. Lever confirms this theory, saying that, in his opinion, the inhaling of the volatile fumes of bisulphate of carbon was the direct cause of all of the mental de-

rangement. The Board of Health has ordered the proprietor of the works to take greater precautions against the escape of the fumes, and to post notices of the dangerous character of the work, so that the employees may be on their guard.—*Ledger*.

An Unsatisfactory Verdict.

The *Oldham Standard* of July 30th contains the following:

A very singular verdict of a coroner's jury is reported from Failsworth. A girl, who was stated to be "in good health at noon," fell on the kitchen floor while washing on Monday evening, and died. A companion was actually waiting at the time to go with the deceased to Hollinwood Wakes, when she heard a scream, and saw the girl lying upon the floor. A doctor was fetched, who pronounced life extinct, but he was not called at the inquest, and the jury, on the above evidence apparently, returned a verdict of "sudden death from natural causes." If an inquest is any use at all, it surely should be to find out as far as practicable the cause of remarkably sudden deaths.

We have inquired into the circumstances attending the above-mentioned death. The deceased was a girl of 18 years of age, and had always enjoyed excellent health and strength, and had worked up to 5.30 P. M. on the day of her death. She then, it appears, suddenly fell down, and died almost immediately. A medical man was sent for, who found the deceased quite dead, with blood oozing from the mouth and nose. Upon this he stated to the police constable, who inquired into the case, that he believed the death had arisen from natural causes. This again was reported to the coroner by the constable, and repeated at the inquest before the jury, who, upon this haphazard statement, founded the verdict; the medical man who was called in at the time of the death not even being required to give evidence. As a means of ascertaining the cause of death, the inquiry certainly was a useless one; for under no heading could the death be registered, except under that of "cause ill-defined or unknown," a column in the Registrar General's returns which we hope will soon cease to be required. Had the coroner and jury appreciated the importance of the duties that devolved upon them, they would certainly not have remained content under the circumstances to have returned such a verdict as "sudden death from natural causes." The means of ascertaining the exact cause of death were at hand. The medical man who was called in at the time of the death,

after making a proper examination of the body, should have been called to give evidence, and then the jury would have been enabled to return an accurate verdict "in accordance with the evidence," instead of a useless one, founded upon the second-hand opinion of the parish constable.—*Brit. Med. Journ.*, Aug. 20, 1887.

Medicine in Spain.

We are prone to think that the Spanish physicians are too inert to trouble themselves about any subject of public importance. This idea is strengthened by the hesitancy of the Spaniard to rush into print with crude and imperfectly digested theories. Yet it was Carron, a Spaniard, who sacrificed his life to solve the life-history of the "wart" disease, and our contemporary, *Revista, Balear*, No. 19, 1887, contains a summary of the medical report on the epidemic of cholera that visited Valencia in 1885. This report was presented to the Mayor and Council of the city, and is a very elaborate and carefully prepared account of the epidemic, such a report as any country might be justly proud of. The report consists of three parts: the first is occupied in the consideration of the position of the city of Valencia and so forth. The second part consists of the preventive and remedial measures adopted, and the third describes the administrative measures recommended for adoption on the recurrence of a similar epidemic. The very fact that Spaniards do not print much, should cause us to carefully consider what they do publish; men who are unaccustomed to write for publication seldom take up the pen unless they have something very valuable or very unusual to tell.—*The Med. Press and Circular*, August 10, 1887.

A Dangerous Toy.

On August 25th, a boy six years old, living in Philadelphia, came to his death under somewhat singular circumstances. The child, in company with an older brother, was playing on the sidewalk in front of his father's provision store, about 2 o'clock in the afternoon, each boy having a tin fife, about 18 inches long and one-fourth of an inch in diameter, upon which he was blowing. Daniel started to go into the store somewhat hastily, and in doing so tripped and fell on his face, the tube being forced into his throat nearly half its length, when it was broken, the jagged edges at the break severing the wind-pipe and arteries. The child was picked up, the tube removed, and the sufferer car-

ried to a neighboring drug store; but death from hemorrhage resulted in a few minutes after the accident.

Fashion and Dress.

To what trying experiences, to what appalling discomforts have a large portion of the male sex been exposed during the past extraordinary weeks of heat, on account of the inexorable fashion which demands the persistent use of the black tall hat, the black frock coat, the gloves, and the umbrella. It seems, after all, curious in the extreme that men should thus consent to make martyrs of themselves because of the dictates of fashion. Fashion in dress, with few exceptions, has been, and probably always will be, unphysiological. Now-a-days a business man only wears even a white waistcoat in an apologetic sort of way, and yet every one is agreed in regard to the suitability and comfort of these garments in hot weather. Why, then, should we condemn ourselves to mundane purgatory, and sacrifice health, good temper, and energy in the process? Health and fashion, it must be conceded, stand widely apart, having apparently rival interests. Fashion in many respects, indeed, resembles a butterfly which flutters into the presence of a pack of schoolboys. Every one follows it, helter-skelter, each doing his best to secure it. The butterfly flutters on and suddenly disappears, no one knows where; then comes the reckoning. Fortunately, however, the general law of mortality peculiar to organic bodies is operative also as far as fashions are concerned. Fashions die out and succumb to the effects of time, but for long afterwards it is possible to trace their effects. There is much cause for regret that nineteenth-century wisdom has not been able to devise for the nobler members of mankind a more rational fashion in dress; in hot weather a man swelters in his apparel, in cold weather his clothing affords him the opportunity of acquiring the habit of shivering, and in each case he has only fashion to thank for the result.—*Med. Press and Circular*, July 20th, 1887.

Diphtheria in Animals.

The report by Dr. George Turner, which has just been issued by the Local Government Board, on the subject of the existence of a disease in animals bearing a striking analogy to diphtheria in human beings, is a step further on the path which was first started when the possibility of infection be-

ing conveyed from animal to man, and *vice versa*, was recognized. From Dr. Turner's observations, it would seem that a certain reciprocity exists between man and animals in the inter-communication of this particular disease. Epidemics of diphtheria in human beings have been accompanied by special forms of disease in poultry and domestic animals, and in certain cases the latter has preceded the former. In this way Dr. Turner is disposed to explain outbreaks of diphtheria under circumstances which would seem to render infection from human beings impossible. Now that the results of Dr. Turner's painstaking observation have been made public, further evidence bearing on the subject will doubtless be forthcoming, and light will be thrown on a matter which, however probable, is so far based only on a concatenation of probabilities. Patient and conscientious workers in this field of observation have a rich harvest before them, and the progress already accomplished cannot fail to act as a powerful incentive to further research.—*Med. Press and Circular*, August 10th, 1887.

Legalized Brutality.

Much indignation has been excited at Ilkeston by the case of a child aged 7, who was charged with stealing a silver watch and guard. The child was ordered to be birched. We do not know to whom that duty was entrusted, but it seems to have been carried out with great inhumanity. The following is the certificate of the surgeon to whom the child was taken after its release:

ILKESTON, July 14, 1887.

James Buckbury, aged 7, was brought to me on July 7th, suffering from lacerated wounds over the side and belly, which had been that day inflicted by the policeman's lash. The wounds which I counted were over fifty in number, and had penetrated deep into the cellular and muscular tissue, those on the belly being especially deep. The child was very feverish and sickly. Its little heart was in a most excitable condition, and it complained of acute pain. I prescribed some soothing medicine, and some ointment, etc., to dress the wounds. I have been attending the child since. He is progressing favorably, and the wounds are healing nicely. For a few days he complained of occasional twitches of internal pain, pointing to slight pleurisy. It seemed to me a monstrous thing that a child of such tender years should be beaten in such a brutal manner. I understand also that the child

was arrested and taken out of his bed at one o'clock in the night, and kept in a solitary cell until bail was given next day. I sincerely trust that all this inhuman treatment to a puny little child of seven will leave no blemish on its constitution. Every medical man knows, however, that epilepsy and chorea, and many other convulsive affections, can be often traced directly to a beating or a fright during early childhood.

(Signed) JOHN J. TOBIN,
M. B., M. Ch. (Royal Univ., Ireland.)

When adult garroters are subjected to corporal punishment, the previous intervention of a surgeon is required, and it would seem to be desirable that some precaution at least should be taken against the excessive punishment which seems to have been inflicted in this instance.—*Brit. Med. Journ.*, July 23, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from September 25, 1887, to October 1, 1887:

Lieutenant-Colonel A. K. Smith, Surgeon, granted leave of absence for one month and fourteen days, to take effect upon his being relieved from duty at U. S. Military Academy. S. O. 223, A. G. O., September 24, 1887.

Capt. R. W. Johnson, Assistant Surgeon, granted leave of absence for twenty-one days, to be taken advantage of, so that he will return to his station at latest by the middle of October, 1887. S. O. 204, Divs. Atlantic, September 23, 1887.

First Lieutenant W. D. Dietz, Assistant Surgeon, leave of absence extended one month. S. O. 223, A. G. O., September 24, 1887.

First Lieutenant Wm. L. Knudler, Assistant Surgeon, ordered to accompany Light Battery "F," 4th Art'y., from Ft. Snelling, Minn., to the International Military Encampment at Chicago, Ill. S. O. 97, Dept. Dakota, September 20, 1887.

Changes in the Medical Corps of the Navy for the week ending October 1, 1887:

Assistant Surgeon V. C. B. Means, ordered for examination preliminary to promotion.

Passed Assistant Surgeon E. Z. Derr, detached from Navy Yard, New York, and to the "Nipsic."

Passed Assistant Surgeon Richard Ashbridge, detached from Naval Academy, Annapolis, Md., and to await orders.

Passed Assistant Surgeon A. H. Russell, ordered to the Naval Academy, Annapolis, Md.

Passed Assistant Surgeon C. G. Herndon, detached from Naval Dispensary, Washington, D. C., and to the "Enterprise."

Passed Assistant Surgeon Geo. Arthur, detached from the Museum of Hygiene, Washington, D. C., and to the Naval Dispensary.

Passed Assistant Surgeon S. H. Griffiths, ordered to the Museum of Hygiene, Washington, D. C.

Medical Inspector J. C. Spear, leave of absence granted until July 1, 1888, with permission to leave the United States.

LECTURE.

SOME MORBID CONDITIONS OF THE URINE.

BY DR. F. W. PAVY, F.R.S., OF LONDON.¹

I must first of all express the honor I feel in being invited to meet with you this evening, and next to apologize for impairment of voice due to cold, and for being under the influence of fatigue from travel.

I am before you to say a few words upon certain morbid conditions of the urine, and my hope is that we may compare notes of observations in the old world with observations in the new world. I shall first of all refer to albumin. Albumin in the urine with us was formerly regarded as a matter of the most serious import, but we are now beginning to recognize that a certain amount of albumin in the urine is not always of grave import. My own practice lies very largely with urinary diseases, and patients coming under my care always have the urine examined by an analyst; and I am frequently meeting with a certain amount of albumin in the urine, without its presence being attended with anything that would lead me to suspect that a grave condition exists. In association with diabetes, it is not at all uncommon to find, when the patient first comes under observation, a certain amount of albumin in the urine; but when the patient is put under treatment for the diabetes, it is not infrequently found that the

albumin disappears in the course of a few weeks. In these cases of albumin in the urine, we must look to the general condition of the patient to see whether or not there are other indications of the existence of grave renal disease.

There is another condition which I presume has been brought before the profession in America, in which albumin exists at a certain time of the day, and not at others. I have suggested for this condition the term *cyclic albuminuria*. I have studied these cases for some years past, and I should think that they occur in this country as well as in the old world. I know that they occur in Germany, for the matter has been taken up there and followed out. This condition is observed in persons who are excitable and of a nervous disposition, and as a rule in young persons, although I have met with some cases in the middle-aged. The albumin is to be met with at one time of the day and not at other times. These cases are recognized, as it were, only by accident. Sometimes the urine is examined on account of some pain in the loins, but most frequently these cases are discovered through examinations for life insurance purposes, or for some branch of the civil service, as is required by the Bank of England. So long as the individual maintains the recumbent posture, no albumin will be detected, but in one and a half or two hours after rising the maximum quantity of albumin will be found. As a rule, the quantity of albumin declines toward evening, and on going to bed it has entirely disappeared. Sometimes a trace of albumin is to be found in the afternoon and evening, but the first urine passed on rising in the

¹ An address delivered before the County Medical Society of Philadelphia, September 19, 1887.

morning contains no albumin whatever. These cases seem to be of no serious import. I suppose that the presence of albumin depends on the condition of the vessels. I suppose so, but certain it is that these cases are not associated with any constitutional condition. I now come across quite a large number of them.

I shall next refer to *sugar in the urine*. This is another morbid element which has varying degrees of importance. In young persons it is of the gravest import, while in elderly persons it is not so serious. In early life I have known cases to go on for years, but this is the exception; the usual duration is about two years. Ultimately they all terminate unsatisfactorily. After the middle period of life, however, sugar in the urine has a very different significance. In young subjects we have a disease which seems to be of a progressive nature. Notwithstanding whatever we may do for it, there is something which insidiously progresses in the system and leads ultimately to a fatal termination. But after the middle period of life a good deal depends upon the patient himself. Under proper management the disease may, as a rule, be held under control and the patient live for years in a satisfactory condition, but to accomplish this, rigid measures of treatment must be carried out.

One may express in a very few words, and without advocating any idea or theory, the precise nature of *diabetes mellitus*, or sugar in the urine. I should speak of it as a defective or faulty assimilative action—a faulty chemistry. The elements of the food which we take undergo chemical change in the system, by which they are rendered useful. A certain group of principles entering largely into the composition of our food is the carbohydrates. These principles in diabetes do not undergo their proper chemical change and thus become eliminated from the system. What do we observe in a state of health? A person takes one of the carbohydrate group, it makes no difference which—starch, grape sugar, cane sugar, dextrine, or sugar of milk—they all behave alike in the system, and it is so changed as to be rendered subservient to the requirements of the system. In a state of health, we see nothing more of them. Not so in diabetes. In the diabetic these carbohydrates are no longer consumed. There is a faulty disposal of them. Received into the alimentary canal and afterward absorbed, they do not undergo their proper transformation, but pass off from the system in the form of sugar in the urine; so that I say, looking at these two conditions,

a condition of health and a condition of diabetes, we may describe diabetes as a faulty disposal—a faulty transformation or assimilation of the carbohydrate elements of our food. In diabetes, in proportion as these carbohydrates are taken, so will be the amount of sugar in the urine. This I can say without any hesitation whatever.

In order to follow a case of diabetes satisfactorily, I consider that a quantitative examination of the urine should be made, and, for myself, I feel quite in the dark as to the progress of a case unless I have this quantitative examination. In my own practice, I keep an analyst who examines the urine of patients—a night and morning specimen—and directly I get the analytical report, I can read off exactly the condition I have to deal with. Without this, I should be perfectly in the dark as regards the progress or the severity of the case. It does not do to rely on the specific gravity. I have met with a specific gravity of 1040, without any sugar in the urine. Medical men are often concerned over the specific gravity of the urine. The patient may have been put under treatment, but still the specific gravity keeps up to 1032 or 1035, although the urine is free from sugar. Under these circumstances, I say to the medical practitioner—do not concern yourself with the specific gravity. If the urine is free from sugar, the high specific gravity is a favorable sign, as showing that the kidneys are equal to good work. If the kidneys were diseased, there would be a low specific gravity. The high specific gravity may be kept up by the passage of only a limited quantity of water, and by the nitrogenous diet which the patient is taking adding to the elimination of urea. On the other hand, a low specific gravity may sometimes be met with where there is a considerable quantity of sugar in the urine. I have met with a specific gravity of 1009 or 1010, and yet the urine contained a considerable quantity of sugar. These have been mixed cases of diabetes insipidus and diabetes mellitus. They are proved to be mixed cases by the fact that when the patient is put under proper dietetic treatment, the sugar disappears, but the quantity of urine keeps up. I myself do not attach so much importance to the specific gravity as is done by certain medical men.

In testing the urine for sugar, my opinion is that the copper test is by far the best. We all know that Fehling's solution is the test generally employed, but there is this disadvantage about Fehling's solution, it does not keep well; after being kept some time, it

throws down a precipitate without the presence of sugar. This has led to many mistakes in diagnosis. I have frequently had patients sent to me with the statement that they were suffering with diabetes mellitus, when the only trouble was that a faulty Fehling's solution had been employed. Some years ago, I directed my attention to the question whether or not the ingredients of the Fehling's test could not be put together in the form of a pellet, and the solution be made as required. Certain difficulties were experienced at the outset, but these have been overcome. The pellets, as now made, consist of sulphate of copper in the anhydrous form, Rochelle salt and potash. It is necessary to separate the sulphate of copper from the potash. This is done by first putting in the die sulphate of copper, then a little Rochelle salt, next the potash, and finally more Rochelle salt. The pellet, after being made, is surrounded with waxed paper and kept in a well-stoppered bottle. If properly prepared and handled with care, the cork not being left out of the bottle, these pellets will keep indefinitely. There is this advantage about the pellet—it will never deceive you, for if it is allowed to absorb moisture, it at once becomes unfit for use, the oxide of copper being thrown down in the form of a black precipitate.

In the treatment of diabetes, I attach the greatest importance to diet. I do not consider that you can get on with the management of these cases unless you exclude as far as possible these principles of which there is a faulty assimilation. If sugar appears in the urine, it must previously have existed in the blood. I know from frequent examinations that the blood contains a trace of sugar, which may be represented in figures as from 0.5 to 0.8 part per 1000. In harmony with this condition of the blood, there has been a trace of sugar in the urine.

The ammonio-cupric test is the one I employ as a quantitative test. It consists of Fehling's solution with the addition of ammonia. With the Fehling's solution there is, on the addition of saccharine urine, a precipitate of the suboxide of copper, and for quantitative purposes, this precipitate interferes with the determination of the exact time when complete reduction has taken place. While the presence of ammonia does not interfere with the reduction, it keeps the reduced suboxide in solution, and we get the decoloration without the formation of any precipitate whatever. The addition of ammonia gives a more intense blue color to the Fehling's solution, and this is brought by the reduc-

tion to the color of water without the formation of any precipitate. With the apparatus in perfect order, the quantitative determination can be made in two or three minutes. This test is so delicate that ordinarily, to perform it satisfactorily, you have to dilute the urine 1:20, and where it contains much sugar, 1:40. I usually determine the proportion of sugar per thousand of urine, but if it is desired to determine the number of grains per ounce, this can be done by multiplying the quantity per thousand by 0.4375.

In examining the urine of a diabetic, I generally desire that a night and morning specimen be brought. When a person lives as people ordinarily live in England—that is to say, taking a meal on rising in the morning, breakfast; a meal in the middle of the day, lunch; and a meal in the early part of the evening, dinner—the urine passed on going to bed contains considerably more sugar than the urine passed in the morning. When a person dines in the middle of the day and sups shortly before going to bed, then the conditions are reversed—there is less sugar in the night water than in the morning water. Over and over again, by the quantitative examination of the urine, I have detected errors of diet where the patients have had the greatest desire to keep to what was right. A person who has been passing only a little sugar, brings a specimen which contains a large quantity of sugar. Under such circumstances we must look for some error in the preceding meal. In one case this proved to be blanc-mange which had been made with corn flour. Blanc-mange for the diabetic should be made with cream and gelatine or isinglass. In another case a patient had been passing very little sugar, when suddenly the quantity increased. Careful questioning revealed no error in diet, until it was learned that the patient had substituted for the bran biscuits which he had been using, others said to be “just as good,” which examination showed to be made of the whole meal. I refer to these cases to show the value of the quantitative analysis.

In the treatment of these cases, the exclusion of the carbohydrate elements of the food should be as complete as possible. In the case of a person in the middle period of life, I first put the patient upon a strict diet. Very often the sugar for a time lingers in the urine. It is materially diminished, but has not disappeared. I may also say that I have, in addition, recourse to opium, codeia, or morphia, for I believe that these drugs have an important influence in controlling the disease; or, to put it in other words, they re-

store the assimilative power. Certain it is that under the influence of these drugs and strict diet, sugar after a time disappears from the urine; and after the urine is kept free from sugar for a few months, I find that the individual has a certain amount of assimilative power over the starch of bread. I test this by giving him a couple ounces of bread. Frequently there is no reappearance of sugar. If there is no return after this has been continued two or three weeks, I increase the quantity to three ounces per diem. Then, if there is no return, to four and one-half ounces; and, finally, to six ounces. Then the person is in the position of a small bread eater. I recommend patients to be content with that. They can very well give up potatoes and sugar, but to give up bread is a serious matter with many people. When a person can take six ounces of bread per diem, he is not in an unfavorable condition. Many of these persons can continue to take this quantity of bread with no return of sugar in the urine. If, however, they go further and resume their ordinary diet, there will be a reappearance of sugar. The urine must be taken as the guide. Treating the case in this way, my experience is that, after the middle period of life, these patients do exceedingly well.

I must apologize, Mr. President, for the crudeness of these remarks, for I have had no time for preparation. I thank you most heartily for the attention which you have given me. I cannot close without thanking you and your countrymen for the cordial reception given to myself and my confrères by everyone with whom we have come in contact.

AN UNRECOGNIZED CAUSE OF MANY THROAT AILMENTS.

BY MR. LENNOX BROWNE, F.R.C.S., LONDON.¹

In accepting the very flattering invitation of your President to speak a few words to the members of the Philadelphia County Medical Society, it appeared to me both more becoming and more profitable to offer you some practical remarks explaining the *rationale* of some of the commoner throat ailments, than to attempt to magnify the office of the laryngoscope by the relation of rare and wonderful cases. I was the more inclined to this view because I was well aware that, through the assiduous industry and well-known skill of your President, and other members of your Society, you have for some

years been kept thoroughly posted in all that is new in laryngology.

It is now some ten years since first I sought an objective explanation of the condition known as *globus hystericus*, and since I commenced to make a systematic examination with the laryngoscope of every patient who came to me with this symptom. The result was communicated in a paper to the Congress of Laryngologists held at Milan in 1880. I found that but very few cases indeed are of an hysterical character—that is, of the nature of a phantom sensation—though uterine or ovarian disorder is a not infrequent predisponent, or, at least, concomitant of the throat condition in the female sex.

Extending the term *globus hystericus*, I find that, with hardly an exception, all and every other subjective sensation in the throat is symptomatic of an objective cause. The chief of such feelings are those of a heat, a prickling, a swelling, a weight, a straw, a hair, or other foreign body. A few patients—one especially, a hale farmer—have complained of a feeling of intense cold, which is sometimes relieved, sometimes aggravated, after food-taking. In some instances there is actual pain, with spasm, cramp, and a sensation of choking, and not infrequently there is cough; this symptom varies in degree from a slight hacking, to the loud hyæna-like bark known as nervous laryngeal cough. Many of the cases of so-called laryngeal vertigo, or, as I prefer to call it, of laryngeal epileptiform seizures, are capable of explanation and cure, on the lines I am at present taking.

On examination of the throat of a patient with symptoms such as I have described, one may or may not see chronic congestion and relaxation of the fauces and uvula, enlargement of the tonsils or obstruction by caseated material of the orifices of the crypts, granular pharyngitis, or even laryngeal hyperæmia. Where any one of these conditions is present, treatment thereof may or may not give relief; but none of them represents the class to which I would draw your attention, namely, that in which there is no generally recognized morbid state of local significance.

The results of laryngoscopic investigations in my hands have shown that there is:

1. A varicose, and even truly hemorrhoidal condition of the veins at the base of the dorsum of the tongue, sometimes at the under surface and sides, in which last case it may be symptomatic of mitral insufficiency, or of severe hepatic derangement, or even of cerebral lesion. There is often a similar varicose state of the vessels in the superior surface of the epiglottis.

¹ An address delivered before the Philadelphia County Medical Society, September 19, 1887.

2. An enlargement of the circumvallate papillæ at the back of the tongue, causing the epiglottis to be hindered in its movements—imprisoned, as your President first called it.

Just drawing attention to the fact that the structure of these glands is very similar to that of the tonsils, I may mention that in a few instances I have seen actual blocking of the orifices, similar to the condition known generally as chronic follicular tonsillitis.

I may also note that it is not possible to see these things either with a tongue depressor or in the laryngeal mirror as ordinarily employed. Many observers, especially beginners, seem to consider that their sole aim is to see the vocal cords, and, if these are sound, they write down, "larynx normal:" but they omit to look well to the frame-work. To see this condition of lingual varix and glandular hypertrophy, the mirror must be placed quite high up in the throat.

Where, as is often the case, there is no actual or noticeable enlargement of the thyroid gland, it will be observed, on passing the hand gently over the front of the throat, that there is a distinct fullness of the thyroid isthmus. If the least pressure be made at this situation, the patient—not necessarily a female—will complain that the abnormal sensation is at once excited, and, on being questioned, will admit that when it occurs the collar is felt to be too tight for the neck.

Inquiring into the general health, and happily failing to find any of the more serious lesions to which I have alluded, it will be noted that habitual constipation and a generally defective circulation are both frequent symptoms; while in others there will be concomitant evidences of a varicose diathesis, as rectal hemorrhoids, varicocele, or varicose veins of the extremities.

In females the menstrual flow is often morbidly frequent or excessive, and there are other evidences of an enfeebled vaso-motor control. Abuse of alcohol and tobacco are excitants of the condition; and in the cases of singers or public speakers, defective methods of filling the lungs—forcing the lower registers upward, or other functional fault which may lead to undue strain on the palatopharyngeal muscles and engorgement of the vessels in this region—are fruitful predisponents.

In this connection, I may refer to the accurate explanation offered by your fellow-citizen, Dr. Carl Seiler, of the etiology and pathology of chronic pharyngitis when occurring to voice users.

Some of those obscure cases which come under our occasional notice, of the presence

of small quantities of blood in the mouth, or of the taste thereof on rising from sleep, will be explained by the leakage of one or other of these enlarged and hemorrhoidal venous capillaries in the region now under consideration.

A few words as to treatment. If the case is not of long standing or of aggravated character, correction of the main constitutional cause—cessation of the faulty method of voice production, or prohibition of a vicious habit or indulgence—may be sufficient to effect a cure, but this is rarely the case. Of remedies, I give chalybeates and aperients with digitalis or ergot, as may be indicated. Locally, astringent applications, especially of chloride of zinc or perchloride of iron, are by no means without avail; they can be applied by the patient himself. Gargles as ordinarily employed are useless, and occasionally are productive of exacerbation of the symptoms. Not so if employed by the method known as that of Von Troeltsch. Of lozenges, I find those of muriate of ammonia much more active in leading to resolution of the venous congestion, than those of red gum, rhatany, etc.

Recent investigations show that the astringent properties of tannin have been exaggerated. Where the uvula is relaxed, the snipping of an elongated portion, especially if other functional or constitutional faults are corrected, may lead to a cure; but in a certain proportion of patients in which the promises of the specialist as to the good effects to be gained by the procedure are not realized, the cause of failure will be found in non-recognition of the varicose vessels. Treatment of these is best effected by the galvanocautery point, and it is necessary to seal each individual enlarged vessel. For this purpose it may be necessary to make more than one application. Lastly, there is often a hyperæmic tumefaction of the vessels, glandules, and submucous tissues of the pharynx, nasopharynx, and turbinated bodies; these will also be treated by galvanocautery.

In conclusion, I would say that in case it may be objected that the conditions I have described are but representative of an advanced chronic congestion, I do not deny that such occasionally may be the case. In the majority, however, there are no such antecedents; and where the two exist, the practitioner will fail to cure his pharyngitis, or what not, until he has recognized and treated the varix.

And it is in this light that I have ventured to call attention to the subject as one that is not generally recognized, for beyond a short

communication at Milan by my deceased colleague, Llewelyn Thomas, I have seen no allusion to it in any books or archives, and no notice is taken of it by the great teachers of Vienna. I therefore make no apology for having occupied your time with considerations that may at first appear trivial, or of exaggerated importance.

COMMUNICATIONS.

ROMAN FEVER.

BY GREGORIO FEDELI, M. D., OF ROME.

Rome, the historic and monumental city, the seat of the fine arts, which in every age has attracted the admiration and interest of foreigners, paid little attention, under the old régime, to matters of cleanliness and decency. Nor was the science of public hygiene understood; for in those days there was little fear of this unhealthy locality. At present there is much uneasiness in the minds of travelers; and yet the improvements introduced have been such that the sanitary condition of Rome is second to that of no other city in the world.

A plentiful supply of pure water has been secured, and arrangements have been made for its diffusion in every part of the city. Drains have been enlarged and multiplied, and constructed in accordance with the regulations of modern science. New quarters of the city have been built, and vineyards, gardens and other hotbeds of disease have been destroyed. Wide streets have been opened across the city, the houses in unhealthy localities torn down, and arrangements made for the systematic cleansing of the public ways. There could scarcely fail, therefore, to be an improvement in the hygienic conditions of the city, and consequently in the health of its inhabitants. And then, what is to be said about the benefits resulting from the embankment of the Tiber? Would that it were possible to make that point understood.

Taking these facts into consideration, travelers ought to be re-assured as to the sanitary conditions of the city. Unhappily there are not a few who are not tranquilized. When they come to our city they tremble lest they should be attacked by illness, as if they were in a pestilential climate. If soon after their arrival they are disturbed by some trifling indisposition, immediately they think, "I have taken Roman fever!"

The idea that there exists an especial form of malarial disease, called "Roman fever," I believe has come to pass through the ignorance of foreign physicians practicing in Rome, who are ignorant of the clinical forms prevailing in our climate, and hence make erroneous diagnoses, and adopt wrong treatment, founded upon their respective national methods. Complications and aggravations in the malady follow, and often when the patient is going to die to the erroneous diagnosis of typhoid or typhus fever is added that of Roman fever, and just before death it is called *pernicious fever*. Thus has arisen a conception of an imaginary disease—Roman fever—a disease unknown to Roman physicians. This fact naturally aroused the attention of the scientific medical societies, and at various times they undertook to determine if such a disease as "Roman fever" exists.

The Roman Committee of the Italian Medical Association first discussed the subject, when its members were gathered together to deprecate the irregular admission of a group of foreign medical practitioners into the sanitary affairs of Rome. At this time the real causes of infectious diseases among strangers in Rome were stated with accuracy. These diseases are not due to their residence in Rome, where there exists no special or endemic malady which can be properly denominated Roman fever. Infectious typhoid fevers very rarely occur among the Roman population.

When the writer read before the Royal Medical Academy a paper on the "Therapeutic Properties of the Eucalyptus Globulus," he touched upon the dreaded climate of Rome, and upon the existence of the so-called Roman fever, which is so greatly feared and considered especially incidental to foreigners. The assembly applauded at this point, and in two subsequent sessions treated the interesting subject at large, looking upon it in all its bearings. The conclusion was reached that the general condition of health in Rome might be considered to be normal, and not inferior to that of other large cities, and that there exists no malady peculiar to the soil of Rome.

At the General Congress of the Italian Medical Association, held in Turin some years since, the conclusion was reached that the climate of Rome is one of the best among the principal cities of Europe.

In order to emphasize the assertion that Roman fever is a purely mythical idea, I would further affirm from my own personal knowledge that such a theory never entered

into the heads of the foreign physicians who practiced in Rome many years ago. And yet, at that epoch, Rome was not in as good hygienic condition as it is now. But the crowning proof of the salubrity of our city is the fact of its indemnity from cholera, even when the neighboring cities were seriously infected with this disease, and when a large number of emigrants were coming from these infected districts to Rome.

The climate of Rome has always been regarded as salubrious. Its mild temperature during the winter season is nevertheless subject to rapid changes dependent upon the character of the season—the prevalence of more or less rain; the relative humidity caused by the greater or less domination of the south and south-east winds, which suddenly succeed the dry winds from the north.

The atmosphere is clear and the sky blue; the sun warm, especially in the higher parts of the city, in the public walks, and in the country. Those who do not guard against the effect of such changes are readily attacked by colds, and then by fever of a rheumatic character; bronchial catarrh, pleurisy, pneumonia, catarrh of the digestive organs, sub-acute and also acute arthralgia, arthritis, etc. These forms of disease are also often complicated with malarial and sub-continuous fever, and these often degenerate into typhoid.

A large part of the strangers who come to our Italian metropolis arrive there in a suffering condition, either fatigued by the long journeys they have taken, or affected by the various changes of climate, lodging and method of life incident to their condition as travelers, and operating with greater force during the winter season. This being so, there is not always sufficient care to secure the needed rest, especially as they are anxious to see our historic city in the shortest possible time. So they rise early and set to work, paying little attention to their enfeebled condition.

Before leaving their hotel (and they frequently give preference to the cheapest) they fill their stomachs with coffee, tea and milk, bread and butter, eggs, etc.; and then, either in carriage or on foot they travel the city, visiting churches, museums, galleries, antiquities, etc., and constantly increasing their fatigue. They return to their hotel in the early afternoon heated, wearied, and perhaps also perspiring; and feeling the need of food they eat whatever is set before them, and drink quantities of water. And although our water is exceptionally pure, still I think that in our climate it is desirable to use wine

with moderation. After the meal they exercise again until the approach of evening; that is to say until the sunset makes the air cooler and damper, and therefore especially to be avoided. Others do even worse. They do not return to their hotels for their midday meal, but when they find themselves tired and heated they enter the shops where fruit and other food is sold and eat with avidity. Others go to a café and satisfy their appetite with pastry and anything else which they may fancy, and then continue their excursions until the sun goes down.

It is impossible that such an incorrect and irregular mode of life, continued for a greater or less space of time, should fail to produce functional disorders. Ordinarily the digestive apparatus is the first to suffer; intestinal pain, diarrhoea, often dysentery, thirst, want of appetite and general discomfort are the first symptoms. In order to subdue these morbid manifestations, some people think it wise to use remedies and prescriptions which they have brought with them; or they go and consult an apothecary, asking for a remedy to stop diarrhoea. The apothecary satisfies their desires, giving them a medicine which he considers suitable. This remedy often calms the abdominal troubles, so that the sufferer, thinking himself cured, gives himself no further uneasiness and goes on with his excursions. But the improvement does not continue long. In a short time, with the increase of discomfort, fever preceded by chills is developed; there is aggravated diarrhoea and the stomach is swollen and sensitive to pressure; the tongue is reddish at the edges and coated with white fur; there are pains in the head, thirst, muscular pains, nausea in trying to take food, etc. In other cases there is added to the above mentioned symptoms, irritation and hyperemia of the tonsils, bronchial catarrh and cough. These symptoms justify the diagnosis of rheumatic fever, rheumatic gastric fever, or enteric fever; or, still better, a rheumatic fever, with acute or sub-acute catarrh, gastro enteric, bronchial, etc. In consequence of the recent study of micro-organisms, the diagnosis of fevers has undergone modifications, and the division between ephemeral and continuous fevers has disappeared, and there has been substituted a gradation of typhoid fevers.

These maladies of long continuance are often associated with intermittent malarial fever, the symptoms of which rarely escape the experienced eye of the Roman physician. Such complications, if not recognized and properly treated, may endanger life. This is the rock upon which foreign practitioners

are stranded—they do not know how to distinguish these complications. In consequence, they have conceived the idea of "Roman fever."

The maladies prevalent in Rome are generally of a rheumatic and catarrhal, rarely of an infective type. If the latter prevail among strangers in the city, it is not the result of the climate, *per se*, but of their irregular mode of life, and of the disadvantages of not being subjected to a rational method of treatment.

Now, it may be asked with reason, what then is the rational treatment of these diseases among foreigners? The first thing to be done is to remove the causes which have favored the malady. If rheumatic causes, and dietetic errors have been the chief factors in determining this, diaphoretics, laxatives, sedatives, possibly oily mixtures, tepid baths, corrective draughts, a well-regulated diet, etc., should be prescribed. This mild method of treatment has almost always been found successful in these cases, which I have rarely seen degenerate into infectious, or, as they are now called, typhoid fevers. Their course has been mild and brief, ordinarily not lasting more than two weeks. In more serious and complicated cases the therapeutics must be modified. In cases of sub-acute or acute bronchial catarrh, bronchitis, pleuritic pains, pleurisy, pneumonia, the curative treatment should be directed towards the modification of the phlogistic condition, so as to assist the resolution of the malady.

Experience shows not only that polypharmacy cannot well be borne in our climate, but also that it is positively hurtful to the patient. It is a grave error, under these morbid conditions, to permit the use of alcohol and other stimulants, as is often done by those who in their efforts to help their patients, do not take sufficiently into account either the causes which have produced the illness or the climate which has augmented it. The old sentence, *medicina tota prudentia est*, is often forgotten, and instead of regarding the physician as *naturæ minister*, he considers himself the *Imperator*.

The forms of disease which I have mentioned are those which ordinarily prevail among the strangers visiting Rome, diseases common to every country. Among those, however, who are established in Rome, or who reside there the greater part of the year, or who spend the winter season there, these forms of disease do not often occur. It does happen, nevertheless, that some among these fall ill in consequence of abusing their

strength and exposing themselves to influences which have their natural results in rheumatism, tonsillitis, bronchial catarrh, etc. When young and delicate individuals, or those suffering from constitutional disorders, are attacked by these maladies, the consequences are often deplorable. But no fact is better established than that the greater part of the strangers residing in Rome improve in health, the sufferings for which they have sought its favorable climatic influences diminishing, so that they depart showering benedictions upon Rome and all Italy.

There is then no such thing as "Roman fever;" the illness of a few among the many visitors who come to our city is owing to conditions peculiar to themselves, and not to the climate of Rome, or that of any other city. They fall ill wherever the forces of nature fail.

PREScription-WRITING.

BY WINSLOW ANDERSON, M.D.,

Assistant to Chair of Chemistry and Materia Medica,
Medical Department, University of California, San Francisco.

Success or failure in life often depends on a want of attention to the *minutiæ* appertaining to one's chosen vocation.

Out of several thousand prescriptions examined at any of our leading drug-stores, very few will be found to correspond to the maxim of the Greek physician, Bithynus Asclepiades, upon whose foundation we have been building our prescriptions for nearly 3000 years, "*curare cito, tuto et jucunde*"—cure quickly, safely and pleasantly.

Prescription-writing seems to be a lost art. Possibly the fault can be ascribed to those medical schools in whose curricula it does not receive its merited attention.

Leaving aside the chirography and hieroglyphics of special coinage, and the phraseology indigenous to the alumni of the Æsculapian Temple, which are generally so legible that if a drug clerk can read one or two words in the *recipé*, he will be obliged to guess at the rest, put up the prescription and compliment himself on the success of his translation.

The most frequently committed errors in prescription writing may be classified under four heads, viz:

1. Improper admixture of Latin and English.
2. Improper use of genitive endings.
3. Faulty and ambiguous abbreviations.

4. Incompatibilities.

1. You frequently observe a Latin noun with an English adjective, and *vice versa*, even in printed prescriptions in medical works. Also one drug in Latin and the next in English, as shown in the following copy :

R Quininæ sulphate..... $\bar{3}j$
 Acidi hydrochlorate..... $\bar{3}ss$
 Syr. liquorice..... $\bar{3}j$
 Aquæ, q. s. ad..... $\bar{3}iv$
 M. Sig.—Teaspoonful every 3 hours.

2. Genitive case.

As Latin is the language used for prescriptions, owing to the many well-known advantages it possesses over all other languages for this purpose, it is well for physicians to bear in mind that all the names of the medicines, with all their adjectives, used in the body of the prescription should be put in the genitive case when the quantities of them are expressed.

With very few exceptions, the following simple rules will be found universal for pharmaceutical names :

(a.) All nouns ending in *a*, form the genitive in *æ*.

(b.) All nouns ending in *us*, *um*, *os*, and *on*, form the genitive in *i*.

(c.) *As* becomes *atis*, *is* becomes *idis* or *itis*, *o* becomes *onis*, *x* becomes *cis*.

(d.) All other pharmacopœial nouns form the genitive in *s* or *is*.

Improper use of genitive :

R Sodii bicarbonate..... $\bar{3}j$
 Bismuth subcarbonate..... $\bar{3}ss$
 Liq. calcis..... $\bar{3}j$
 Aquæ, q. s. ad..... $\bar{3}iv$
 M.—Take one teaspoonful after each meal.

3. Abbreviations should be correctly used or not at all. To be sure, the temptation is very great when we are busy, but it should be remembered that a drug clerk cannot divine what is wanted and has the prescription only to go by; and perhaps the life of a human being depends upon an improper abbreviation; therefore we cannot be too careful. Several deaths in this city have been attributed to the stupidity of apothecaries' clerks or criminal carelessness of the prescriber.

The following *original* prescriptions were written by a physician of this city, who enjoyed a lucrative practice for many years and is now deceased. They illustrate the dangerous habit of ambiguous abbreviations and peculiar hieroglyphics :

No. 1.

73114
 Chloral. $\bar{3}j$
 Potass. bromid. $\bar{3}ss$

DR.

These and many other imperfect abbreviations should be carefully avoided :

Hydroc. may mean acidum hydrochloricum, or acidum hydrocyanicum. Hydra. chlor. may be either hydras chloralis or hydrargyri chloridum. Sulph. will stand for sulphas, sulphidum, sulphuris, sulphuratum or sulphurous, and so with many others.

4. Incompatibility in prescribing is of much greater importance than is generally supposed. Pharmaceutically considered, it gives rise to many annoyances little thought

of. For instance, solutions of borax and tincture of the chloride of iron, or syrup of acacia and iron will coalesce, forming a jelly-like mass, which cannot be poured or handled in any way. The patient to obtain his medicine must break the bottle.

Therapeutical incompatibility prevents a proper physiological action of the drug given. Many times we are disappointed in the action of a drug, all the while forgetting that it is our own fault, having combined it with some antagonist. Alkaloids, for example, are precipitated by alkalies and rendered inert by tannic acid or vegetable drugs containing tannin, forming insoluble tannates. Tinctures contain resins, spirits contain oils, hence are *not* miscible with water, and yet fully one-half of all prescribers will use water as a vehicle for tinctures. Fluid extracts are generally miscible with water.

Chemical incompatibility is the most important, as dangerous compounds are formed. Hydrocyanic acid or potassic cyanide with metallic hydrates or carbonates will form poisonous compounds. So will potassic iodide with potassic chlorate.

We have all witnessed syrup of squills and ammonia carbonate mixed, with the sequence of blowing the cork out or breaking the bottle, due to the formation of CO₂.

Pepsin should be given with acids and not with alkalies or carbonates.

Plumbic acetate is incompatible with zinc sulphate. In prescribing potassic iodide with bichloride of mercury, you form iodide of mercury, the strength depending upon the amount of the one or the other salt present. Poisonous compounds are formed by mixing together arsenic, iodides and a salt of mercury, and yet this is a standard mixture employed by many physicians.

Many prescriptions I have seen were composed of tinctures and vegetable drugs containing more or less tannic acid and preparations of iron; several of them would give you very good writing inks.

The following is one of our *legible* prescriptions, written by a prominent physician. It might be much improved upon as far as compatibility and simplicity are concerned:

[¹The difficulty of translating the prescription may be appreciated by the fact that we would make the fifth ingredient *syr. scillæ* and not *syr. sennæ*, as the author does.—EDS. REPORTER.]

Prescriptions for liniments containing tincture of iodine, aqua ammonia and soap liniment, often used, will make iodide of nitrogen, which is explosive under certain conditions.

Gargles of chlorate of potassium, tincture of the chloride of iron and glycerine will explode if warmed.

Silver nitrate with creosote, occasionally used for steam atomization, may explode. Potassium chlorate with sugar or glycerine, tannin with permanganate of potassium, oxide of silver pills, chromic acid or nitro-hydrochloric, with oils and fats, sulphur or sulphides with chlorate of potassium, all form highly explosive compounds and should be avoided.

The stronger acids should be prescribed alone with proper diluents. Potassium iodide, chlorate and permanganate, corrosive sublimate, lead acetate, silver nitrate, the cyanides and nitro-glycerine should all be prescribed in simple solutions, and *mono* rather than *poly* pharmacy adopted.

Many rare gems of curious composition could be given, but want of space and prudence forbid.

In conclusion I would urge medical men, students and professors to pay more attention to prescription writing. The time has happily gone by when it was considered learned and wise to write so that nobody could read it. Master the genitive endings, and by all means avoid abbreviations that are ambiguous and unintelligible. Oftentimes the only means a pharmacist, or indeed the public, has of judging of the qualifications of a physician is by his prescriptions.

OBLITERATION OF THE ORIFICE OF THE NOSE—OPERATION—RELIEF.

BY GILBERT YOUNG, A.M., M.D., OF PHILA.

The following case presented such a marked degree of deformity, and was so much relieved by a simple operation, that I think it not unworthy of being placed on record.

The patient, Mrs. —, was about forty years old when she came under my care. She had contracted syphilis twelve years before, and in consequence of ulcerative lesions of the face, had suffered a deformity of the most pronounced character. Not only was her countenance so changed that her nearest friend could not have recognized her, but also great destruction had taken place within the nasal cavity.

The nasal bones and inferior turbinated, on both sides, as well as the cartilaginous septum and lower half of the bony septum, were completely gone—no opening or semblance of one remaining over the original site of the anterior nasal aperture.

An orifice, about three-quarters of an inch square, existed in the palatal processes of the superior maxilla, just posterior to their anterior, inferior juncture. Through this square hole the finger could be passed high into the nasal vault.

The soft palate, uvula and tonsils had not sloughed; but from the amount of aphonia present, I concluded there had been serious impairment of the vocal cords. An examination of the larynx was, however, rendered almost impossible, from the fact that the opening of the mouth of the patient, which was naturally small, had, by the inroad of the disease at this point, become diminished at least one-third of its original extent. The skin, too, of the entire central portion of the face, including the lower part of the forehead, the original site of the nose, both cheeks, and the upper lip, presented a thickened, corrugated, pink-and-white, streaked, cicatricial appearance.

Again, the patient was cachectic, requiring—perhaps from a neglect of sufficiently prolonged, early, constitutional treatment—frequent recurrence to alteratives, in order to keep her fairly well. Added to this, having for twelve years been so long required to breathe entirely through her mouth, her fauces were so irritable that she suffered of late, among other inconveniences, from most alarming attacks of spasm of the glottis. These were repeated so many times daily and nightly, and were so prolonged, that she was gradually wearing out, and an immediate operation of some kind seemed demanded for her relief.

On the second of June, without anesthesia, I made as long a vertical incision in the median line, over the site of the nasal fossa, as its space permitted. The tissues were about half an inch thick, and very hard. With my left index finger passed up through the opening in the bony palate (before mentioned) as a guide, I next made a horizontal incision on a line with the floor of the nares, at right angles with the first.

Into the opening made by pressing apart the two triangular flaps, I inserted a No. 20 (American scale) soft catheter, passing it well back into the posterior nares, and bringing its outer end, chimney-like, up to the forehead, fastened it there with adhesive plaster.

After wearing the catheter about a month, of course cleansing it frequently, the artificial canal to the anterior nares seemed well healed, and since then my patient has worn a well-fitting metal tube, with great comfort.

As an immediate result of this trifling operation, there was at once, has since been, and I hope will continue to be, an almost complete relief from the very distressing attacks of spasm of the glottis which she previously suffered.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Special meeting, September 19, 1887.

The President, Dr. J. SOLIS COHEN, in the chair.

The discussion upon Dr. PAVY's address on "**Some Morbid Conditions of the Urine,**"¹ was opened by

DR. JAMES TYSON, who said: It is needless to say how much indebted we all feel to Dr. Pavy for his remarks, and in the brief time allowed for discussion I desire first to say that I think we, in America, have passed through much the same transition in our views as to the import of albumin in the urine as has taken place in England. The fact is thoroughly recognized that albumin may be present without any serious import; but the explanation of these curious albuminurias is still unsatisfactory. There are a certain number of them which are clearly the result of diet, and may be called alimentary albuminurias, but that all cases cannot be thus explained is shown not only by the cases alluded to by Dr. Pavy, but also in those in which the urine on rising is free from albumin, but in which within an hour afterward the urine passed is albuminous, although no breakfast has been taken.

The crucial test for the determination of the gravity of an albuminuria is the presence or absence of casts. I have found that in these harmless albuminurias tube casts are invariably absent; and where there is a constant association of albumin and tube casts, it, of course, means renal disease, no matter how slight the general symptoms may be.

With reference to sugar, we also entertain much the same views. In my hands Fehling's solution has proved the most satisfactory test, although open to the disadvantages alluded

to by Dr. Pavy. Much, however, may be done to preserve it; if the bottle is kept corked and in a dark place, the solution will keep for a much longer time. I have also obtained satisfactory results in this respect from a Fehling's solution in which mannite was sub-tituted for the tartrate of potassium and sodium. I have found that the pellets made in this country rapidly spoil.

In reference to the treatment we largely agree. I am inclined to believe that certain sugars, and especially certain fruit sugars, are better managed by the diabetic than others. Thus I think that a patient may eat an apple, or even an orange, without much disadvantage, whereas the use of grapes is always attended with an increase in the quantity of sugar. The same is true of milk sugar. I am satisfied that milk is a good diet for most diabetics, although, of course, it is not a cure. The dietetic treatment is, for the most, efficient; but, so far as my experience with drugs goes, I am satisfied also that the preparations of opium, and especially codeine, are the most efficient adjuncts to the dietetic treatment. They are, however, open to the objection that they produce constipation, which almost always aggravates the other symptoms of diabetes.

DR. J. W. HOLLAND said: The remarks of the previous speaker have reminded me of my experience with glycerine as an organic medium in Fehling's solution. This makes a solution which keeps for a considerable time, although not indefinitely. At the Jefferson College laboratory we employ two solutions of definite strength, one containing the sulphate of copper, and the other Rochelle salt and the caustic potash or soda. These are mixed in equal quantities when it is desired to employ the test.

In the use of Dr. Pavy's quantitative test, I find one small objection—which can be obviated by extreme care—that is, if the solution is boiled in an ordinary capsule the ammonia will be driven off and reoxidation of the copper follows. If a flask is employed the ammonia will not escape so rapidly.

One form of pellet lately brought to my attention is the indigo-carmine pellet. This seems to keep indefinitely. It is composed of sodium carbonate and the sulphindigotate of sodium. It is a very sensitive test—even more sensitive than Fehling's solution.

DR. KLEEN, of Carlsbad, was introduced, and said: I had two years ago, under my care at Carlsbad, a most singular case. Mm. X., of Gothenburg, fifty years old, then consulted me, telling me that she was suffering with diabetes, that the illness had acci-

¹ See page 503 of the REPORTER.

dently been discovered the year before, and that she had then visited Carlsbad (1884) and consulted Professor Seegen (who since that time has retired from practice).

Mm. X., when I saw her, presented no symptoms of diabetes or of any other illness, except some nervous debility. I gave her a considerable quantity (100 grammes) of cane sugar, collected the urine for some hours, and afterward for twenty-four hours, but found no glucose in it. I did not succeed better after she had dined copiously on rice and other amylaceous food. I then pronounced her free from diabetes. I still kept the case under observation, however, and at last found, upon examining the urine two hours after a meal, which had ended with a large portion of sweet fruits (mostly pears), a small quantity of reducing substance. Both Fehling's and Nylander's (bismuth) solutions showed reactions corresponding to the one we got, with urine containing 0.1–0.2 per cent. of glucose. When testing the urine with polarization by the spectroscope, I found, to my utter surprise, a slight deviation *to the left*. The urine did not contain a trace of albumin. I was at a loss what to think of it, and submitted it to the test of fermentation. The same day, however, I received a letter from Prof. Seegen, stating that when the patient was under his care, her urine had contained much larger quantities (as much as 3 per cent.) of reducing substance, and that he had found that substance to be *levulose*. At the same time Professor Seegen sent me a supply of glucose, asking me to submit the patient to a test of her toleration of that substance. So I did, and found that portions of 100 grammes or more did not produce more than very small quantities of reducing substance in the urine—that substance, to judge from a very slight deviation to the left in a good instrument, being levulose.

Worm-Müller has proved that glucose, administered in large doses, passes to a certain (small) extent unchanged into the urine, even in healthy persons, while it passes to a much larger amount into the urine of the diabetic patient. He has also found that all the different species of sugar, administered in large doses, in a certain (small) proportion pass *unchanged* into the urine even of healthy persons, while in the diabetic patient at least some portion of them passes into the urine *transformed into glucose*. He believes in this latter circumstance to have found a difference, also, between persons suffering from real diabetes and those whose urine, while under ordinary

diet with the common reagents, presents traces of glucose, or only now and then, under peculiar circumstances and in a passing manner, contains somewhat larger quantities of it.

This coincides with my own experience so far as it hitherto goes. Like all physicians who occupy themselves with researches in this direction, I find every year persons whose urine shows traces of sugar, and now and then—especially after strong emotions, after alcoholic excesses, or after very rich meals of mixed food (but generally, not after meals *exclusively* consisting of amylacea or of cane sugar)—in a passing manner, somewhat greater quantities of a substance which shows *all* the qualities of glucose. In these doubtful cases, I usually give a large quantity of cane sugar; and afterward often find no glucose—or only slight traces of it—in the urine, till I have boiled it with mineral acid, and thus converted a portion of the cane sugar that has passed over into glucose, whereupon I will find the well-known reaction of glucose. I consider these cases to be distinct from true diabetes, though it seems to me highly probable that they indicate a tendency to that disease, which others of larger experience than myself have also noticed—for instance, Professor Frerichs.

In the present remarkable case of levuluria, I found that some portion of cane sugar passed unchanged into the urine. It seemed to me to be of great interest to find out how Mm. X. reacted against the other species of sugar, especially against levulose, which, with some reason, could be expected to pass over in larger proportion than in quite normal persons. I therefore had the wish to administer a large amount of honey (which is a mixture of glucose and levulose), and also to make a test with milk sugar; but Mm. X., who had heard that she should avoid sugar above all things, and who had an interest in her own case, only partly of the same nature as my own, did not wish to be submitted to further experiments, especially as I could not promise that they would be without some momentary influence on the urine. I can, therefore, only give the above description of the case, such as is always given by Professor Seegen, who first discovered it, but I am not without hope of being able in the future to give fuller information upon it.

I am decidedly of the opinion that the case is not, clinically speaking, strictly one of diabetes. If the substance had been glucose, it would have ranged among the large number of the above-named glycosurias con-

tinuing unchanged for a great number of years in healthy or nearly healthy persons. I was rather astonished at seeing Professor Seegen state that the urine once contained as much as three per cent. of levulose, but cannot doubt the accuracy of this most excellent observer. That the quantity has diminished so very much without any dietetic treatment, makes the case even more interesting than it otherwise would be. I allowed Mm. X. a tolerably good supply of starchy food, advised her only to avoid excessive use of them, and I have lately heard that the urine only now and then contains small quantities of reducing substance.

In the discussion on Dr. Lennox Browne's address on

"An Unrecognized Cause of Many Throat Ailments,"¹

Dr. CARL SEILER said:

I quite agree with the speaker, that the *globus hystericus* is rarely of purely imaginary origin. Some chronic inflammation of

the upper part of the upper air passages usually accompanies this distressing condition. As he truly says, pharyngitis is one of the most common causes of this symptom. At the same time the pharyngitis is to my mind, as a rule, the consequence of remote causes which may be looked for in one of three different directions—in a disturbance of the gastric system, in a disturbance of the respiratory function of the nose and naso-pharynx, and, finally, and most commonly in public speakers and singers, in a faulty use of the organ of voice. This latter condition is frequently met with in those who simply use the voice for ordinary conversation. The constant irritation thus produced leads to hyperæmia and chronic inflammation, which extends upward, rather than downward, into the trachea. In the treatment of the condition described, I think that little can be accomplished by the application of remedies to the apparent seat of the disease, but that the cause must be looked for and removed.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Traumatic Tetanus Cured.

Dr. Mayer makes the following communication to the *Allgemeine med. Central-Zeitung*, August 6th, 1887:

P. Reckert, nineteen years old, of strong physique, wantonly wounded himself on the point of his left forefinger in trying to break a china plate with his hands. On the evening of the third day after the wounding, the patient noticed, after being wet through by a cold rain, that he could no longer open his mouth. As this was accompanied during the night by painful contractions of the muscles of the neck and back, I was consulted next morning, and found the patient in the following condition: The teeth of the upper and lower jaw were firmly pressed together, so that I was only able with an effort to get the handle of a spoon between them. The expression of the face was grinning, as in risus sardonicus, through distortion of the muscles of the angles of the mouth. Swallowing was very difficult; speech stammering. From the mouth saliva constantly dribbled. The pupils of both eyes were very much contracted. At times there were very painful convulsions in all the muscles, so that the whole body was as rigid and immovable as a statue. During these convulsions breathing was very difficult and entirely superficial. About thirty such

convulsions occurred in the first twenty-four hours, though of different duration and intensity. After these symptoms, it could not be doubted that we had to deal with traumatic tetanus, which had been occasioned by cold. The patient, for the first fourteen days, was put upon fifteen grains of bromide of potash and fifteen grains of chloral alternately every hour, so that he took 180 grains a day of each. From the second day of the treatment the patient fell into a slumberous condition, while at the same time a diminution in the frequency and violence of the convulsions was noticeable. After fourteen days opisthotonos completely disappeared, and there only remained for some days longer a waxy rigidity of the chin muscles. From this time on the chloral was discontinued, but the bromide was continued in the same doses four weeks longer. On the forty-eighth day after being taken sick the patient was dismissed from treatment as completely cured, but for six months general weakness of the body and inability to work persisted.

Investigation into Cholera Infection Received Through the Blood.

The following are the conclusions arrived at by Prof. Guido Tizzoni and Dr. Guisepino Cattani, in a preliminary communication to the *Centralblatt f. d. med. Wissensch.*, August 13th, 1887:

1. That it is possible to obtain in animals infection in an acute form through

¹ See p. 506 REPORTER.

the injection of even a small quantity of the poison of cholera into the blood whenever the animals concerned yield the same conditions which are necessary for artificially calling forth infection in other ways

2. That by injections alone, even copious ones, of cholera poison into the blood, no result is obtained.

3. That the comma bacilli that are injected into the blood are preserved there some time, and are still capable of culture after twenty hours.

4. After the lapse of a certain time, whose length varied in the different experiments, and after which the comma bacilli were no longer demonstrable in the blood, they still persisted in the peritoneal serum and in the organs, but, especially, in experiments covering some time, in the spleen.

5. The negative results which the contents of the intestines, the bile and the urine afford, prove that the comma bacilli that penetrate into the blood are not expelled from the latter in this way.

6. Although it may be further assumed that if death can be brought about through a small quantity of cholera poison, as was the case in our experiments, that this increase may occur in the blood; and, although upon the above-designated grounds it could not be proved, whether this increase occurred directly in the blood, or in other fluids of the organism, or in the organs, yet at the very least one may be permitted to doubt very much, contrary to the achievements of Hueppe, that this increase necessarily takes place in the intestinal contents as the place of least resistance.

7. Finally, we cannot avoid directing attention to the facts indicated by us of the constant passage of comma bacilli from the blood into the peritoneal serum, as well as of their presence in this fluid, even when they are no longer demonstrable in the blood itself, which would be sufficient to explain how, in acute cases of cholera, arising in the natural way, the comma bacilli, which have penetrated into the blood, pass from this at once into the serous fluids. We have proved this in one case by culture of the cerebrospinal fluid itself.

Methylene Chloride as a Narcotic.

In a long paper upon this subject in the *Deutsche Medizinal-Zeitung*, August 22, 1887, Eichholz and Genther sum up their conclusions in the following propositions:

1. The preparation hitherto sold as methylene chloride is a mixture of chloroform and methyl alcohol.

2. This mixture of chloroform and methyl alcohol is to be preferred to chloroform for the production of narcosis.

3. The pure methylene chloride produces narcosis just as quickly and just as profoundly as both of the above named preparations, but is not so lasting in its action.

4. The action of the pure methylene chloride upon the circulation and respiration is, moreover, not so dangerous as the other two preparations.

Transmission of Tuberculosis by Flies.

Drs. Spillmann and Haushalter have made a communication to the French Academy of Sciences from which it appears that the common house fly probably plays an important role in the carrying of tubercle bacilli. These observers have been struck by the great numbers of flies who are in the habit of collecting about the spit-cups of consumptive patients in hospital wards. Having taken some of the flies, they placed them under a bell-glass, and after the flies had died they examined the excrement which had been left in the form of blackened tracks upon the sides of the glass, and found without difficulty numerous bacilli, which were also seen in the intestine. Now, as the flies are known to die under the walls, tapestries and carpets, after the drying of their bodies the tubercle bacilli become free again in the dust and can infect inhabitants of the room.

The authors therefore conclude that flies, as carriers of contagion, should be kept from phthisical spit-cups by covering the latter with a lid, and that flies should be carefully kept away from food and drink.—*Le Concours Médical*, September 3, 1887.

The Value of Turkish Baths in Diseases of the Circulation.

In a recent paper Frey records his experience as to the value of Turkish baths in patients suffering from disturbances in the circulation. He first of all determined the normal effects of such baths by observations on himself with special reference to their influence on the pulse, arterial tension, respiratory capacity, renal excretion, and body weight generally. According to these observations, the quantity of blood in the body is lessened by the free excretion which takes place through the skin and lungs; the body weight is reduced; and the work of the heart is in this way lightened, at the same time that its substance is better nourished by the improved quality of the blood supplied to it. The peripheral arterioles of the

body, too, become dilated and filled with blood, thus effecting a corresponding emptying of the vessels of the internal organs. At the same time albuminous bodies, and still more fat, become more rapidly broken up, the loss in weight being thus explained. Lastly, as the result of the alternate warm and cold douching, the vaso motor energy of the vessels is increased, thus rendering them more capable of resisting any strain thrown upon them.

The good effects of the Turkish baths in disease find their explanation in these physiological considerations. Thus the diminution in weight is well illustrated in cases of *obesity*. By such patients the baths are extremely well borne. The only precaution necessary is that the cold douche ought not to be used in such cases, as the sudden shock produced, acting on a heart overloaded with fat, or the fibres of which may already have become fatty, may readily prove dangerous. In all cases it is important to have regard to this rule—that the sweating stage ought never to be continued after the pulse rises above 100. The diastole of the heart then becomes too short to allow sufficient time for the heart to nourish itself; and under such circumstances the effect of the bath is to weaken rather than to strengthen the cardiac action.

In cases of *aortic and mitral disease* dependent upon rheumatic affection and not the result of atheroma, the baths are also well borne. This effect is most marked in cases in which compensation is disturbed, with anasarca of limbs, failure in secretion of urine, and dilated right heart. So far from the pulse gaining in frequency under the influence of the bath, after the first ten to fifteen minutes it generally falls, remaining between 90 and 100 as soon as perspiration commences; it becomes softer, less tense, more dicrotic in character; visible arteries, *e.g.*, the temporal, are seen to distend; and respiration becomes freer, deeper, and sometimes even more slow. In the after treatment the cold douche is in the first instance to be avoided, a douche at the temperature of the body being used instead. The bath can be repeated daily, or on alternate days, according to the strength of the patient. As improvement goes on recourse is gradually had to colder douches, then finally the coldest of all may be freely used. The tone of the heart and vessels is in this way greatly improved.

In cases of *chronic Bright's disease*, where there is hypertrophy of the left ventricle, œdema of the legs, increase in albu-

min, and some failure in the secretion of urine, the baths also prove useful. It is necessary to have care in the use of the cold douche. By *emphysematous* patients, on the other hand, the Turkish bath is not well borne. In their case the use of the vapor-bath proves far more efficacious, and is often extremely beneficial. Lastly, in all conditions characterized by disturbances in the circulation dependent upon weakness, local or general, *e.g.*, œdema of the lower limbs or around joints, the result of general weakness, paralysis, rheumatic affections, etc., the Turkish bath proves of great value. It is, indeed, under such circumstances that the full effects of the baths in improving nutrition, and raising the general vaso-motor tone, are best observed.—*The Practitioner*, July 1, 1887.

Localized Facial Sweating.

Dr. Rice reports the following case to the *Brit. Med. Journ.*, August 20, 1887:

In the *Journal* of July 9th I see reference made to two cases of localized facial sweating. As it is there spoken of as being exceedingly rare, it may be interesting to your readers to know that I have a patient under my care at the present time who suffers from it in a marked degree. My patient is gouty, and he first noticed the affection after a sharp attack of gout some seven years ago, which appears to have affected his right ear, making him deaf for some time. The sweating is profuse, and comes on at any time; in fact, is generally present, the sweat pouring off the upper part of the right temple, and, when he is lying on his back, running into the right ear. Curiously enough during the present summer he has had suppuration of the right parotid, which at the present moment is not quite healed. In both the cases mentioned the sweating was preceded by parotid abscess; in mine the sweating preceded by many years the abscess. There appears to be no loss of sensibility in the skin from which the sweating proceeds, neither is the hair over the surface affected. It would be interesting to know of any further cases, and of the combination of localized sweating and parotid abscess.

Experiments on the Preventive Inoculation of Rattlesnake Venom.

Dr. Henry Sewall gives a detailed account of his experiments upon preventive inoculation of rattlesnake poison in the *Journal of Physiology*, August, 1887. The following is an abstract of his paper:

The venom used in these experiments was obtained from three specimens of the *Masasanga*, *Crotalophorus tergeminus*, one of the smallest of the rattlesnakes. The average length of the reptiles was about two feet. In order to obtain the poison the snake was allowed to bite the side of a porcelain dish while being held round the neck by a loop fastened to the end of a stick. The number and variety of the experiments performed were narrowly limited by the small amount of venom obtained. After the first extraction of poison, only one snake gave an additional amount; nor did artificial feeding with chopped meat induce a further secretion.

It was sought to artificially excite the secretion by stimulating with an induction current the exposed poison gland and its nerves. The results, on the whole, were negative, though in one instance stimulation of the gland was followed by a slight flow of venom into the capillary tube inserted in the poison duct, and each application of the electrodes caused a greatly accelerated blood-flow from the cut muscles which had covered the gland. The total amount of venom obtained was estimated to be about six small drops, though as part of it dried after extraction an accurate measure was impossible. The six drops of venom were dissolved in about 88 drops of glycerine, as recommended by Weir Mitchell¹, so that each drop of the glycerine-venom contained .068 drop of the pure venom. The venom was clear and greenish-yellow in color and decidedly acid in reaction. In preparing for an inoculation, the requisite number of drops of glycerine-venom were allowed to fall into a porcelain capsule and diluted with distilled water to such an extent that each animal should receive 15 minims of the mixture.

Mitchell and others have found that pigeons are peculiarly sensitive to the influence of rattlesnake poison, and these birds were therefore uniformly used in the experiments. The inoculations were made under the skin of the back by means of a hypodermic syringe.

In no case did death follow injection so rapidly as described in some of the experiments of other workers on this subject; this result may have been due either to the high dilution of my poison, or to its intrinsic composition. There appeared to be two well-marked periods within which death followed after inoculation with the venom;

the shorter time was about 3 hours, and the longer 15 to 20 hours.

The first symptom of the action of the poison was invariably a weakness in the legs, inducing the pigeon to sit down or to move with a tottering gait when forced to rise. Complete paralysis of the legs follows a larger dose of the venom. The general health and appetite of the bird may remain apparently unaffected while the legs are nearly completely paralyzed. Another symptom of the poisoning is the apparently excessive lachrymal secretion. When a fatal dose of poison is given, the paralysis extends from the legs to the wings; the head rests upon the floor; the mouth is open and the respiration gasping, and, after a longer or shorter period of clonic convulsions, the pigeon dies.

Mitchell draws attention to the marked effect which the inoculation of rattlesnake venom has in rendering the blood incoagulable, in producing extensive extravasation from the blood-vessels and in hastening putrefactive decomposition with the formation of very offensive odors. None of these results could be verified, perhaps on account of the dilute condition of the poison with which this work was done.

Previous observers seem to agree that snake venom may be kept indefinitely without diminution of its virulence; but, in the absence of quantitative experiments to the contrary, I think my own results are valid as showing that rattlesnake venom preserved in glycerine undergoes a gradual deterioration in its power. On consulting the tabular statement of the experiments on prophylaxis (for which see the original), it will be seen that on Nov. 7th the fatal dose of glycerine-venom was two-fifths drop; on Dec. 2d it had risen to two-thirds drop; and on May 19th nearly one drop was injected into a pigeon without producing death. A yellow color, such as is occasioned by fat, marked the skin for a considerable area round the needle punctures. In some of the experiments the pigeons inoculated with the same amounts of venom were divided in two lots, those of one being preserved in a room kept fairly constantly heated to about 60° F., while the others were caged in an unheated room in which the temperature frequently descended to 50° F. The poison seemed to affect more seriously those pigeons preserved in the cold room.

A review of the foregoing table of experiments shows that repeated inoculations of pigeons with sub-lethal doses of rattlesnake venom produces a continually increasing re-

¹ "Researches on the Venom of the Rattlesnake." *Smithsonian Contrib. to Knowledge*, 1861.

sistance towards the injurious effects of the poison without apparent influence on the general health of the animals. On December 3d, when the fatal dose of glycerine-venom is less than $\frac{2}{3}$ drop, $4\frac{1}{2}$ drops, or about 7 times the fatal dose, were injected without the least effect into pigeon I. The efficiency of resistance against the venom gradually fails in the absence of fresh inoculation, as is witnessed in the case of pigeon I which is perceptibly weakened by the inoculation on January 6th of 3 drops of glycerine-venom, a little more than one month after $4\frac{1}{2}$ drops had been injected without effect. Also on April 29th, nearly five months after the next preceding inoculation of 2 drops of the poison, III and IV were killed by inoculation, the one with 3 and the other with 2 drops of the poison. That the prophylactic effect of the repeated inoculations is persistent over the interval of five months is shown by the example of pigeon II, which on May 6th is uninjured by a fatal dose of the poison, and thereafter rapidly recovers its powers of resistance against the ill effects of inoculation with doses of venom much in excess of the fatal amount.

BOOK REVIEWS.

Insanity: its Classification, Diagnosis and Treatment. By E. C. Spitzka, M.D., President of the New York Neurological Society, etc. 8vo, pp. 423. New York: E. B. Treat, 1887. Price, \$2.75.

One of the most interesting questions which have engaged the attention of alienists within the last few years has been the significance to be attached to the term "Monomania." In this discussion Spitzka has borne a most important part, and he may well regard with gratification the general acceptance at present of views which he contended for against the vigorous opposition of a considerable number of specialists in insanity. We congratulate him upon the appearance of the book before us, which presents the sum of his opinions on this as well as other phases of insanity in his characteristic sharp, crisp style. Spitzka's opinions are positively expressed, which is a great advantage to the reader when, as we believe is the case here, an author's opinions are sound. This book contains an admirable summary of the present knowledge in regard to insanity, and is a valuable contribution to the literature of the subject. We hope the next addition may be as creditable to the publisher as this one is to the author.

Differential Diagnosis of the Diseases of the Skin. By Condict W. Cutler, M.S., M.D., etc. $6\frac{3}{4} \times 5\frac{1}{2}$ in., pp. viii, 139. New York: G. P. Putnam's Sons, 1887. Price, \$1.25.

This little book contains in parallel columns the symptoms of diseases of the skin which are liable to be confounded one with another. As an illustration of the way in which this is done, we may cite the presentation of "Measles," the symptoms of which are confounded with those of scarlet fever, r  theln, small-pox, roseola and erythematous syphilide. The statements of the author are founded upon the teachings of well known dermatologists and are no doubt reliable. We believe the book is calculated to be helpful to those to whom the diagnosis of diseases of the skin is a puzzling matter; but it cannot take the place of good, systematic books on dermatology.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The first number of the *Revue Internationale Scientifique et populaire des Falsifications des Denr  es alimentaires* appeared September 17, 1887. It is published in Amsterdam, and edited by Dr. P. F. Van Hamel Roos, with the aid of a large number of co-editors in Europe and in North and South America. The object of this new journal—one number of which is to be issued every two months—is to diffuse information in regard to adulterations of food; what they are, how to detect them, and how to prevent or stop them. Such a worthy object must insure the sympathy of all good physicians and good citizens.

—Ginn & Company, of Boston, announce that it has been decided to establish a "Journal of Morphology," devoted principally to embryological, anatomical and histological subjects. Cordial promises of support have been received from many of the most eminent investigators in this department. The Journal will be edited by C. O. Whitman, Director of the Lake Laboratory, Milwaukee, Wis., and will be issued in two numbers a year, of 100 to 150 pages each, with from five to ten double plates. Subscription price, \$6.00 a year. Single numbers, \$3.50.

—Messrs. Longmans, Green & Co., have established a Branch House at No. 15 East Sixteenth Street, New York. Among their recent publications they announce, "*The Health of Nations.*" A Review of the Works of Edwin Chadwick, C.B., with Biographical Dissertation by B. W. Richardson, M.D., and "*The Commonwealth,*" A Series of Essays on Health and Felicity for Every-Day Readers, by Benjamin Ward Richardson, M.D., F.R.S.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D., } EDITORS.
CHARLES W. DULLES, M. D., }

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium,	6.00
Physician's Daily Pocket Record,	1.50
Reporter and Pocket Record,	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

THE NATURE OF TETANUS.

At the last International Medical Congress several papers were read, and interesting remarks were made, on the nature and treatment of tetanus. Certain of the speakers were inclined to accept the theory of the microbic origin of this disorder, and some seemed inclined to the view recently advanced by Verneuil that tetanus is naturally a disease of horses, and that it is communicated to man by association with them.

The first of these opinions has not a little evidence in its favor, although it is far from proved, and stands in apparent opposition to well-known clinical experience. Prof. Gaston, of Atlanta, took occasion to state some of the objections to the microbic theory of the nature of tetanus; and we think it worth while to make some comments of our own upon it.

The strongest arguments in favor of this theory depend upon the results of experiment. About a year ago, Rosenbach, of

Göttingen, read a paper before the Fifteenth Congress of German Surgeons, in which he gave a summary of what had been done by others before him, and added an account of some experiments of his own. Carle and Rat-tone succeeded in producing tetanus in eleven out of twelve rabbits by inoculating them with the contents of acne pustules.

Nicolaier believed that the germ of tetanus was to be found in the earth, and he produced symptoms like those of tetanus in rabbits by inoculating them with the soil of a garden. Rosenbach took material from the frozen and gangrenous foot of a man suffering with tetanus, and inoculated two Guinea-pigs, which developed symptoms of tetanus and died in about twenty-four hours. Material taken from the seat of inoculation in these animals produced similar symptoms in four new Guinea-pigs and eleven mice. Cultivations of a bacillus, which Rosenbach isolated, proved active at his hands as far as the fourth generation. These experiments are, however, not so conclusive as some have thought. In the first place, the animals experimented upon are so sensitive to experimental inoculation that we cannot safely argue from them to human beings. In the second place, the specific germ described has never, so far as we know, been found in the tissues of human beings, and in the animals experimented on it has been found in entirely inadequate numbers. Again, the clinical history of tetanus is often irreconcilable with the germ theory, cases occurring idiopathically—without any presumable supposition of inoculation—and some developing so rapidly, and terminating in so short a time, as to preclude the idea of germ development sufficient to account for the phenomena. Nicaise has reported a case caused by dashing a glass of cold water in the face of an infant; and many of our readers have no doubt seen cases of trismus nascentium in which no germ infection could be rationally imagined. Other cases occur which cannot be explained except by attributing them to the effect of cold. Such a case came under the observation of the writer not long since. Still other cases seem to be, at least in part, the result

of strong mental impressions acting upon neurotic subjects. In fact, we believe that none of the theories offered in regard to the nature of tetanus is so weak and purely hypothetical as the germ theory.

The "equine theory," as it has been called, has found little acceptance outside of France, where it first saw the light. It rests upon assumptions which will not bear the most ordinary scrutiny. It may be that one or two French surgeons have found that patients with tetanus have been associated with horses, as grooms or stable-men; but we have no idea that such association could be traced to even a small proportion of the cases occurring all over the world. Certainly, the babies affected with trismus nascentium could hardly be put in the same category with the stable-men alluded to. Dogs are very prone to tetanus; but we believe no one has ever suggested that men get it from dogs.

On looking over the whole subject, we must come to the conclusion that we have as yet no sound theory as to the nature of tetanus, and must take care to avoid a hasty acceptance of plausible hypotheses in regard to it. Meanwhile, we must patiently study the phenomena of this disorder, in the hope that some day the difficulties which surround it may be overcome, and a correct opinion be established.

COLLEGE OF PHYSICIANS AND SURGEONS.

The new edifice for the College of Physicians and Surgeons, for the erection of which the late Wm. H. Vanderbilt gave half a million of dollars, was formerly opened on September 29, with addresses by Dr. J. C. Dalton, the President; Dr. C. B. Agnew and Dr. Barnard, of the Board of Trustees. The building stands opposite the Roosevelt Hospital, and extends clear through the block from Fifty-ninth to Sixtieth street. The material is of the best Haverstraw brick. In fitting it up special attention has been paid to the practical work for which it is destined, rather than to art or ornament, and yet the edifice is one of the handsomest of its kind in the city.

NOTES AND COMMENTS.

A Case of Occlusion of the Vagina with Retention of Menstrual Fluid.

Dr. C. J. Cullingworth, of Manchester, England, reports the following case in the *Med. Chron.*, September, 1887:

The case I am about to describe is of considerable interest, as being a typical example of the simplest and most common form of vaginal atresia.

Ann A., aged 19, single, a factory worker, residing at Moses Gate, near Bolton, was sent to me by my friend, Dr. W. E. Bradley, of Farnworth, on August 17th, 1886.

She was a strong, well-built, healthy girl, with the development natural for her age. She had never menstruated, nor had she suffered any inconvenience therefrom until a few weeks ago, when she had some pain in the lower part of the abdomen. Soon after this she perceived that the abdomen was swollen. The pain recurred the following month, and she then consulted Dr. Bradley, who forthwith examined her, and, recognizing her condition, suggested that she should see me at once with a view to operation.

When she presented herself at my rooms there was a tense, smooth, elastic tumor centrally situated immediately above the pubes, with a smaller and more solid body resting on its summit. On passing a finger into the rectum, a large tense elastic swelling was felt in front, bulging the anterior wall of the bowel backward. A bimannual examination proved this swelling to be directly continuous with that in the abdomen. The patient being placed on her back, with her knees flexed and separated, nothing unusual was observable in the appearance of the vulva until the labia were separated, when the vaginal orifice was seen to be occluded by a thick membrane, resembling mucous membrane in appearance, and bulging very slightly outwards. Through this membrane an elastic mass could be felt, continuous with that perceived in the rectum and above the pubes. On more close examination the hymen was found to be of its usual shape, spread out upon the outer surface of the membrane and intimately adherent to it. It was arranged that the operation should be performed on the following day at the girl's own home.

Accordingly at 4.30 p. m., on August 18th, the patient was placed on her back at the edge of a table, in a good light, with the knees flexed and separated. In accordance with her wish, no anæsthetic was given. Seating myself before the patient, I punctured

the occluding membrane by means of a Cock's curved trocar, which had been previously immersed in a solution of carbolic acid, and lubricated with carbolic oil. On removing the trocar a dark brown fluid, of the consistence of treacle, began to flow through the canula. No pressure over the hypogastrium was employed, or any other means of hastening the evacuation of the fluid. The stream continued to flow slowly and steadily for an hour and a half, at the end of which time it began to pass in drops only. I therefore withdrew the canula, and inserted a pair of small polypus forceps, opening the blades so as to dilate the aperture sufficiently to admit the finger. The vaginal wall was much hypertrophied; its mucous membrane felt perfectly smooth: the cervix uteri was not within reach. I now again enlarged the opening by incising its posterior margin on a director. The quantity of fluid removed during the operation was altogether 32 fluid ounces.

A strip of lint, saturated with carbolic oil (1 in 10) was placed in the vagina, and a large pledget of the same was laid over the vulva. The patient was then lifted carefully into bed. No douching was used, any fluid that still remained being allowed to trickle away gradually as the patient lay in bed. Orders were given to observe the recumbent posture absolutely for two days, then to be allowed to sit up, during meals and whilst passing urine, for purposes of drainage. A small glass dilator was to be introduced as soon as there was noticed any tendency to contraction.

On August 22d, Dr. Bradley writes, "The patient has not had the slightest untoward symptom; there has been no increase in the rate of the pulse or any elevation of temperature. Discharge somewhat copious until yesterday, when it almost ceased, so that to-day I managed to dilate the opening with my finger and inserted the glass tube." The discharge retained its dark treacly character for five days; it then became yellowish, and finally consisted entirely of mucus. On August 28th the patient left her bed in the afternoon, and on September 2d she was up to breakfast, and remained up all day. I saw her on September 13th at my rooms in Manchester. She was looking and feeling very well. She still wore the glass dilator, which she was able to pass herself, retaining it by means of a napkin. From this time she was told she might discontinue its use in the day time, but must wear it at night until Dr. Bradley thought it safe for her to discard it altogether. On August 25th, 1887, it being now exactly a year since the operation, the

patient called upon me at my own request. She is perfectly well, and menstruates with a fair amount of regularity, and without any discomfort. For some months she wore the glass dilator every night; now she wears it about one night a week as a matter of precaution. On examination, the vaginal orifice is normal, the hymen remaining perfect. The shrivelled remains of the divided membrane can be seen behind the hymen, but are a source of no inconvenience. The vagina is of ordinary length; its walls are still destitute of rugæ, but are no longer hypertrophied. There is no trace of the abdominal swelling. The uterus is normal, both in size, position, and mobility.

Remarks.—The cases of which this is an example are often described as instances of imperforate hymen. The obstruction is, however, not at the hymen, but just behind it; the hymen frequently, as in this case, lying upon the obstructing membrane, and so closely adherent to it, as only to be with difficulty recognized as a separate structure.

The dangers attending the evacuation of retained menstrual fluid are well known; they are chiefly (*a*) rupture of one of the Fallopian tubes, which are often irregularly distended or sacculated by accumulations of blood in their canal; and (*b*) septicæmia. The former of these dangers is best avoided by evacuating the retained fluid slowly. It was with this object that I made a small opening at first, allowing the fluid to escape very gradually, and it was also this that influenced me in avoiding all pressure over the hypogastrium during the operation. The second danger is to be guarded against by careful antiseptic cleansing of fingers and instruments, and by the avoidance, as far as possible, of the admission of air into the vagina, both during and after the operation.

With regard to the desirability of washing out the parts after the operation with warm carbolized water, or other antiseptic solution, authorities are divided in opinion. My own observations have led me to the conclusion that in cases where no putrefactive change has taken place in the retained fluid, it is better to let it drain away of itself. This was the plan I adopted in the case above recorded, and certainly, no case could have progressed more satisfactorily. Whether the successful result was due, in any degree, to the avoidance of douching, or whether, as the advocates of douching would say, it occurred in spite of it, cannot of course be determined. One thing, however, is clear, namely, that antiseptic washing out of the vagina is not essential to uninterrupted recovery.

Uniformity in Obstetrical Nomenclature.

The committee appointed by the Section in Obstetrics of the Ninth International Medical Congress to formulate resolutions in regard to the above subject submitted the following report, which, after an animated discussion, was unanimously accepted, the only dissentient being Dr. Martin, of Berlin, who was not present, but had left a message stating that he thought the matter should not be settled by an American Congress, but should wait three years and be accepted or not by a congress meeting in the Old World.

A. It is desirable to try to attain to uniformity in obstetrical nomenclature.

B. It is possible to arrive at uniformity of expression in regard to: 1, The Pelvic Diameters; 2, The Diameters of the Fœtal Head; 3, The Presentations of the Fœtus; 4, The Positions of the Fœtus; 5, The Stages of Labor; 6, The Factors of Labor.

C. The following definitions and designations are worthy of general adoption by obstetric teachers and authors:

1. PELVIC BRIM DIAMETERS.—1. Antero-posterior: (1) Between the middle of the sacral promontory and the point in the upper border of the symphysis pubis crossed by the *linea terminalis* = *Diameter Conjugata vera*, Cv. (2) Between the middle of the promontory of the sacrum and the lower border of the symphysis pubis = *Diameter Conjugata diagonalis*, Cd.

2. Transverse: Between the most distant points in the right and left ileo-pectineal lines = *Diameter Transversa*, T.

3. First Oblique: Between right sacro-iliac synchondrosis and left pectineal eminence = *Diameter Diagonalis Dextra*, D. D.

4. Second Oblique: Between left sacro-iliac synchondrosis and right pectineal eminence = *Diameter Diagonalis Læva*, D. L.

II. FœTAL HEAD DIAMETERS.—1. From the tip of the occipital bone to the centre of the lower margin of the chin = *Diameter Occipito-Mentalis*, O. M.

2. From the occipital protuberance to the root of the nose = *Diameter Occipito-Frontalis*, O. F.

3. From the point of union of the neck and occiput to the centre of the anterior fontanelle = *Diameter sub-Occipito-Bregmatica*, s. O. B.

4. Between the two parietal protuberances = *Diameter Bi-Parietalis*, Bi-P.

5. Between the two lower extremities of the coronal suture = *Diameter Bi-Temporalis*, Bi-T.

III. PRESENTATION OF THE FœTUS.—The

presenting part is the part which is touched by the finger through the vaginal canal, or which, during labor, is bounded by the girdle of resistance.

The *occiput* is the portion of the head lying behind the posterior fontanelle.

The *sinciput* is the portion of the head lying in front of the *bregma* (or anterior fontanelle).

The *vertex* is the portion of the head lying between the fontanelles and extending laterally to the parietal protuberances.

Three groups of presentations are to be recognized, two of which have the long axis of the fœtus in correspondence with the long axis of the uterus, while in the third the long axis of the fœtus is more oblique or transverse to the uterine axis.

1. Longitudinal: (1) Cephalic, including—vertex and its modifications; face and its modifications; (2) pelvic, including—breech; feet.

2. Transverse or trunk, including shoulder, or arm and other rarer presentations.

IV. POSITIONS OF THE FœTUS.—The positions of the fœtus are best named topographically, according as the denominator looks—first, to the left or the right side, and second, anteriorly or posteriorly. When initial letters are employed it is desirable to use the initials of the Latin words.

In the case of Vertex positions we have:

Left Occipito-Anterior = *Occipito-Læva-Anterior*, O. L. A.

Left Occipito-Posterior = *Occipito-Læva-Posterior*, O. L. P.

Right Occipito-Posterior = *Occipito-Dextra-Posterior*, O. D. P.

Right Occipito-Anterior = *Occipito-Dextra-Anterior*, O. D. A.

The Face positions are:

Right Mento-Posterior = *Mento-Dextra-Posterior*, M. D. P.

Right Mento-Anterior = *Mento-Dextra-Anterior*, M. D. A.

Left Mento-Anterior = *Mento-Læva-Anterior*, M. L. A.

Left Mento-Posterior = *Mento-Læva-Posterior*, M. L. P.

The Pelvic positions are:

Left Sacro-Anterior = *Sacro-Læva-Anterior*, S. L. A.

Left Sacro-Posterior = *Sacro-Læva-Posterior*, S. L. P.

Right Sacro-Posterior = *Sacro-Dextra-Posterior*, S. D. P.

Right Sacro-Anterior = *Sacro-Dextra-Anterior*, S. D. A.

The Shoulder presentations are (left and right side of the *mother*):

Left Scapula-Anterior = *Scapula-Læva-Anterior*, Sc. L. A.

Left Scapula-Posterior = *Scapula-Læva-Posterior*, Sc. L. P.

Right Scapula-Posterior = *Scapula-Dextra-Posterior*, Sc. D. P.

Right Scapula-Anterior = *Scapula-Dextra-Anterior*, Sc. D. A.

V. THE STAGES OF LABOR.—Labor is divisible into three stages: (1) First stage—from the commencement of regular pains till complete dilatation of the os externum = *Stage of Effacement and Dilatation*. (2) Second stage—from dilatation of os externum till complete extrusion of child = *Stage of Expulsion*. (3) Third stage—from expulsion of child to complete extrusion of placenta and membranes = *Stage of the After-Birth*.

VI. THE FACTORS OF LABOR ARE—(1) The Powers. (2) The Passages. (3) The Passengers.

Alcohol in High Latitudes.

In spite of the discovery of so many new remedies and the discussion resulting therefrom, the main battle of argument is still waged about alcohol. Commission after commission has contributed its decisions, and still the question is unsettled. Recent decisive testimony upon one phase of it, however, has been given by General Greely, of Arctic exploration fame, and his recent utterances in the *Forum* are most timely.

The last half-century has witnessed a marked reduction in the amount of alcohol supplied to men engaged in exploration in the high latitudes. The experience of previous years has finally made itself felt in official utterance. In one of the recent British expeditions, Sir Alexander Armstrong, Medical Director of the Navy, expressly counselled against alcohol rations for regular distribution, and advocated in their stead the use of cocoa and tea, but the officers in charge saw fit to allow the men two ounces of rum daily and double that amount during the absence of the sun.

One-fifth of the officers and over one-half of the men suffered from scurvy.

In Greely's expedition the amount of spirits taken was calculated on the basis of

four ounces per man weekly. In the long period of exposure to which the latter party was subjected, it was indisputably shown that spirits given on the march impaired resistance to cold. Given in small quantities after the day's work was over, they distinctly stimulated the mental faculties, without any unpleasant effects. This small quantity was generally about two ounces. More than this seemed merely a waste. In the later history of the expedition, it was recorded that one-fourth of an ounce of pure alcohol, diluted with three times its weight of water, had an equally pronounced effect. It seemed to supply food and to have a decided alimentary value. These results are what have been claimed for alcohol ever since its physiological effects have been critically studied. Their integrity has often been assailed by well-meaning but misguided enthusiasts, to whom anything concerning alcohol savors only of the powers of darkness. Upon them all argument is wasted.

General Greely's observations are valuable additions to our knowledge concerning alcohol. The facts which they narrate were indeed known before, but they have now received an authentic confirmation, and that, too, under the most trying circumstances.—*Med. Record*, October 1, 1887.

An Emulsion of Cod Liver Oil.

Emlen Painter suggests the following emulsion:

R	Irish moss gelatine.....	40 grains.
	Boiling water.....	5 fl. ounces.
	Cod liver oil.....	8 “ “
	Syrup of tolu.....	2 “ “
	Alcohol.....	1 “ “
	Oil of saffraas.....	10 minims.
	Oil of wintergreen.....	10 “
	Oil of bitter almond.....	2 “

Dissolve the gelatine in the boiling water, taking pains to have it completely in solution; transfer the mucilage formed to a pint bottle; gradually add the oil in divided portions, and shake the bottle vigorously after each addition and until a perfect emulsion is formed; then incorporate the syrup, and lastly add the alcohol in which the essential oils have been previously dissolved, and shake well together.

If preferred, this emulsion may also be made in a mortar in the usual way, and it is probably better to let the mucilage become perfectly cold before proceeding further with the emulsion.—*Druggist's Journal*, September, 1887.

Ligation of the External Iliac Artery under Cocaine.

Dr. Howe presented at the meeting of the N. Y. Path. Soc. (April 13, 1887), the specimen taken from a man whose external iliac artery he had ligated. It was accompanied by the following history:

John W., aged twenty one, single, of Irish birth, and a boilermaker, entered the hospital January 18, 1887, complaining of severe pain in the right leg, and especially along the inner side of the thigh. It had begun five days before this, and was accompanied by numbness of the limb and severe pain on attempting to walk.

In September of the previous year he had suffered from an attack of typhoid fever. He had also several severe attacks of acute articular rheumatism, and for four years believed his heart to have been affected, although he had never suffered from it further than from slight dyspnoea on exertion.

There were no evidences of venereal disease, and no history of alcoholic excess.

On examination the heart was found to be acting strongly; the pulse-rate was about 90. There was a loud mitral regurgitant murmur, and also an aortic regurgitant. The lungs and the abdominal organs showed nothing abnormal. The urine was examined with negative results. Locally, nothing was found to account for the pain. The patient was in a fair general condition, although somewhat anæmic. There was a slight elevation of temperature daily.

On the 25th, the second and third toes were found to be livid, and the whole extremity was cold and somewhat swollen.

On February 1st, a slight swelling was noticed immediately below Poupart's ligament in the line of the femoral artery, and this rapidly increased in size. By the 15th, there was a swelling the size of a hen's egg, which showed pulsation and presented a well-marked bruit. Pressure could not be applied below Poupart's ligament, and was very badly tolerated above.

The circulation had improved in the leg, and there was less tendency to gangrene. The patient's general condition had grown worse, and morphine had to be freely used to secure relief from the pain. He was then transferred to the surgical side of the hospital for treatment. The aneurism still continued to increase very rapidly in size, and on February 27th, scarcely four weeks from its first appearance, the skin over it was livid and softened, and rupture of the sac seemed imminent. Without hope of permanently benefiting the patient, but simply to do away

with the danger of sudden death from rupture of the sac, he ligated the external iliac artery, first, however, injecting into the subcutaneous cellular tissue, over the artery, fifteen minims of a four per cent. solution of cocaine. This quantity of cocaine sufficed to make the operation a painless one, excepting at its termination, when the edges of the wound had to be widely separated to get at the artery.

On the third day after operation there was free oozing from the wound, which was opened and a search made for bleeding points. Slight compression was all that was necessary, however, to control it. On the sixth the temperature rose to $104\frac{1}{2}^{\circ}$, and the abdomen became swollen and painful. The ligature came away on the ninth. He grew weaker rapidly, and on the tenth he died.

The autopsy showed the heart to be hypertrophied, and the aortic and mitral valves roughened and covered with vegetations. The pericardial sac contained a large amount of fluid. The lungs were congested. The intestines were distended. In the right iliac region, near the seat of operation, there were some fibrinous adhesions. There was no effusion. Both extremities of the ligated artery showed firm clots.

The points of interest in this case are first, the rapid development of a femoral aneurism in a young, bed-ridden patient; and second, the successful performance of the operation, without pain, by the use of cocaine as a local anæsthetic.

In this connection he wished to state that he had also amputated the mammary gland for scirrhus, in St. Francis Hospital, using during the whole operation forty minims of a four per cent. solution of cocaine. The operation was completed without pain, but at its termination the patient vomited. Whether this was the result of the cocaine or from shock, he was not prepared to say. These are the first cases of the kind on record where cocaine has been used instead of ether or chloroform.

Dr. Wyeth remarked, with regard to Dr. Howe's first case, that it was very unusual for constitutional effects to be developed by the injection of twenty minims of a four per cent. solution of cocaine, and he made this remark because he was so much in favor of the use of cocaine in surgery that he would dislike to have it discarded through fear to employ it. To be sure, it was not impossible for the effect mentioned by Dr. Howe to occur as a consequence of this moderate quantity, but as he had used the drug very extensively for the purpose of producing local anæsthesia, and had seen its unpleasant

constitutional effects produced in only one case, and that where a drachm of this solution became actually forced into the tissues, he believed that the cases in which such effects would be produced were very rare.—*Med. Record*, August 13, 1887.

Unusual Symptoms from Quinine.

Dr. Tsoukales reports in *Galenos* of June 20th, 1887, the case of a man of healthy antecedents to whom he gave twenty grains of sulphate of quinine in divided doses for a fever accompanying a severe attack of laryngitis. A short time after taking the first dose the man began to complain of a feeling of formication and numbness of the scrotum and penis. This passed off in a few minutes, and was followed by an intense itching, which persisted for about three days. The dartos of the scrotum was strongly contracted: the skin being drawn into tight folds. When the itching subsided, it was succeeded in some parts by a branny desquamation, but chiefly by fissures running parallel with the median raphe from the root of the penis to the perineum. These fissures also formed on the glans from the meatus to the corona. There was at first some bleeding from the cracks and then a purulent secretion. After the itching ceased the patient complained of pretty severe pains in the testicles. The fissures were healed, after the application of drying powders, in about a week. A week later another dose of quinine was given, and was followed by the same phenomena.—*Med. Record*, Sept. 3d, 1887.

A Case of Wellnigh Fatal Hemorrhage from the Conjunctivæ.

Dr. Pomeroy reports the following case in the *Med. Rec.*, Aug. 20, 1887: B. A—, a male child, from the middle walks of life, was born of healthy parents on April 30, 1887. The physician did not arrive until after the child was born. Mother had excessive uterine hemorrhage, which reduced her to an almost pulseless condition, and the most prompt measures were required to restore her. She, however, made a rapid recovery.

On account of the mother's requiring so much attention the child's eyes were not specially attended to until the next day, at about 12 M., when two drops of a two per cent. solution of arg. nit. in water were placed upon the slightly separated eyelids. The doctor thinks that not more than one drop came in contact with the palpebral conjunctivæ: this was at once neutralized with a solution of salt and water. The drops

were applied from a spoon, and no laceration of the conjunctivæ resulted from opening the lids.

At once the most violent pain resulted, which continued for five or six hours, the child crying constantly during this time.

At about 7 or 8 P.M. a serous discharge was then noticed from the eyes, which in two or three hours became tinged with blood.

This continued as a slow oozing during the night, becoming more sanguinolent until about ten o'clock of the next day, when the doctor arrived. He found it to be now almost wholly sanguinolent. He at once used cold applications which, having no effect, were changed to hot. Neither of these succeeding, resort was had to digital compression. This arrested the hemorrhage during the contact of the fingers, but as soon as the fingers were removed bleeding recommenced. I arrived at 1 P.M. Compresses of absorbent cotton, with vaseline to prevent imbibition, were at once applied by means of a firmly applied bandage; this arrested the hemorrhage for an hour, but it again returned, first in one, and after a little in the other, when two more bandages were applied over the first. This controlled the hemorrhage until 6 P.M., when it again commenced. At 8 P.M. I again saw the patient, and found the bandage soaked with nearly or quite pure blood, clots readily forming beneath the eyelids.

Iced applications were now made with temporary success: this failing after an hour or an hour and a half, the upper lids were everted and touched with alum in substance. This did no good; the slow but persistent oozing of blood was startling to observe.

A compress was then applied very firmly, with sheet rubber applied to the eyelids, knowing that blood *could not* soak into the cotton compresses. The bandage was applied very tightly indeed, the attending obstetrician reminding me that a child's head in the inferior straits was often compressed for hours with great intensity without harm. The bleeding now ceased.

This compress remained thirty six hours; on removing it, it was found that the left had not bled a particle, but the right had lost about half a drachm.

The bandage was reapplied to the right for one day, when there was found to be no more hemorrhage. Blood-clots were found beneath each eyelid, but it was thought injudicious to remove them, and a bichloride collyrium was used.

On the next day the clots were found to have disappeared, and a saturated solution of

boric acid in water was ordered to be used twice a day.

The lids were now carefully inspected, and each upper lid showed that there had been a superficial slough. The retro tarsal folds were considerably swollen, but the corneæ were perfect. Child opened the eyes readily; no photophobia; continued wash.

At the third day it seemed as though the child might die. The pulse was very feeble; patient extremely quiet; respiration weak; showed inability to nurse, for hours at a time, and when it did so only caught the nipple feebly. It was estimated that four ounces of blood had been lost. Stimulants were used, and in two days the child rallied satisfactorily, so that in a week there was no further trouble. The parents seem fairly healthy and strong; the mother, it is true, had serious post-partum hemorrhage, but there was no tendency toward being hæmophyllic, nor is there a history of anything of the kind in the family. The child only bled from the conjunctivæ.

I found it difficult for a time to believe that the collyrium could be the cause of the trouble; not more than a single drop touched the palpebral conjunctivæ, not a particle touched the globes on account of somewhat imperfect separation of the eyelids, and the prompt neutralization of the collyrium by a solution of sod. chlorid. still further rendered the application apparently safe. Three weeks after the instillation both upper eyelids exhibited a minute cicatrix.

I have made ineffectual efforts to obtain an exact examination of the solution, to determine whether it was properly dispensed. By the chloride-of-sodium solution I thought a more dense precipitate was thrown down than in the case of a solution known to be two per cent. It evidently was not *much* stronger than intended.

"Chichipate" and Cascara Amarga.

Plant Analysis as an Applied Science is the title of a lecture delivered before the Franklin Institute of Philadelphia last winter, by Helen C. De S. Abbott, for a copy of which in its published form we are indebted to the author. Among the personal observations mentioned—and it was to them that the lecture owed its value—is one of a Honduras plant called "chichipate," from which the author has extracted a yellow dye, *chichipatin*. Specimens of *Cascara amarga* having been sent to her from Messrs. Parke, Davis & Co.'s laboratory, where it had been found to contain an alkaloid resem-

bling berberine, she came to the conclusion that the two plants were identical. "This incident is significant," she remarks, "as deciding by means of chemical analysis the identity of plants under distinct names from different regions."—*N. Y. Med. Journal*.

A New Explanation of Renal Troubles, Eclampsia and Other Pathological Phenomena of Pregnancy and Labor.

A. F. A. King (Washington) has written a long paper on this subject, and advanced a new theory of the renal affections of pregnancy. The paper does not admit of sufficient condensation to warrant its reproduction in this report by abstract; but all who are interested in the subject will do well to read the article in detail. Briefly stated, the author's theory is that "disturbances in the renal circulation and renal functions are produced chiefly by pressure of the gravid uterus upon the abdominal aorta or its branches, or upon the vena cava or its branches, or upon both or all of these, in consequence of the child and womb not maintaining during pregnancy their normal lateral obliquity above the pelvic brim." The author submits that the normal position of the uterus before the advent of labor is the lateral oblique position, and that "the normal presentation and position of the foetus in utero during pregnancy, before labor begins, is the dorso anterior position of an oblique presentation." He also declares that the normal position of the child and womb is "intrinsically the same in primiparæ as in multiparæ," and that it is abnormal for the foetal head in primiparæ to enter the pelvis before the advent of labor. Dr. King then proceeds to show that "when the normal obliquity of womb and child is maintained during pregnancy, there will be no injurious compression upon any blood vessels."

The author's theory is ingenious and is modestly presented; he admits that his views are theoretical and only hopes that they may stimulate research which will verify or disprove them. While many will not now accept his premises, those who have large clinical facilities will do well to examine them with care and give them that clinical test which alone will determine their value. —*Boston M. & S. J.*, August 25, 1887.

—Dr. Austin Meldon writes to the *Medical Press and Circular* that he has for some years been treating tetanus with a combination of hyoscyamus, belladonna and conium. Seventeen cases have been treated in all, with thirteen recoveries and four deaths.

CORRESPONDENCE.

Papoid.

EDS. MED. AND SURG. REPORTER :

Sirs :—How shall I order papoid, if I want to use it? and where? and what will it cost?

Yours respectfully, R. S. W.

[Papoid is probably the same thing as papain. It is prepared under this copyrighted name by a firm in New York, and may be obtained from any druggist in Philadelphia at \$2.00 per ounce, or about a cent per grain, in prescription. Papoid costs \$3.00 per ounce, and probably more per grain than papain. In prescribing papain, or papoid, for internal use it may be dissolved in a mixture of equal parts of glycerine and water, or in either alone, or it may be ordered in capsules or cachets. The dose for acid dyspepsia, or intestinal catarrh is from one-half to one grain for children, and from two to five grains for adults. It may be combined with an alkali, such as bicarbonate of soda. For local application, it may be dissolved in from five to ten times its weight of water, or simply rubbed up with enough water to make a paste, as recommended by Dr. Wilmoret in the REPORTER, Oct. 1, 1887, p. 441.—EDS. REPORTER.]

EDS. OF MEDICAL AND SURG. REPORTER :

Sirs :—On reading your editorial in the REPORTER for September 17th I am reminded of an accident in my own practice, which was due to carelessness on the part of the druggist. I prescribed, for a delicate young lady, a grain of calomel divided in eight powders, one to be taken every hour. The patient took three of the powders as ordered, in spite of violent pain and ineffectual efforts at vomiting. I was sent for, and soon had all I could do to rescue her from the effects of three doses of an eighth of a grain of corrosive sublimate.

The mistake occurred as follows. I wrote

R Hydrarg. chlor. mitis gr. j

Sacch. albæ.....grs. viij

M.—Div. in chart. No. viij.

Sig.—One every hour.

The druggist gave the prescription to his assistant to compound, and while he was doing this, called out to him in joke, "Are you sure you are putting corrosive sublimate in that prescription of Doctor —'s?" At this, the assistant threw away the powders of calomel he had prepared, and deliberately made up a new lot with *corrosive sublimate substituted for the calomel!*

Such a mistake as this, if it had resulted fatally, would undoubtedly have subjected the druggist to a charge of manslaughter; and I am not sure but that it ought to have driven him out of the delicate business of pharmacy. Fortunately for all concerned, the results of his and his clerk's folly were only temporary, and the matter was not made public.

I publish this, hoping it may come under the notice of other druggists.

Yours respectfully, S. T. D.

EDS. MED. AND SURG. REPORTER :

Sirs :—I was interested in your editorial, in the September 17th number of the REPORTER, on "Accidents in Prescribing." Some mistakes are inexplicable except upon the hypothesis that the party making them must be insane, or his mind engaged on something altogether foreign to what he is doing at the time. If all of the mistakes were to go into print, I imagine we would be treated to a pretty constant succession of surprises. They have always been happening, and often will occasionally. It only behooves us to be more and more careful. I know a reputable physician who gave a patient a fatal dose of corrosive sublimate for potassium bromide. The fact was not published. Why publish it?—the harm had been done—he was suffering enough.

I don't approve of your Rule 2. Fancy that you had prescribed for a patient; the medicine had been sent labeled "poison;" a part had been given; and in the meantime the patient had unfortunately died. Fancy the nurse, a widow, with dyspepsia and strong religious convictions—such an one as Fothergill so aptly describes as the ghoul of the sick room—calling the attention of the friends of the deceased to the vial with the poison label, and telling them "that's what did it." Yours respectfully,

GEO. P. BLUNDELL, M. D.

Yazoo City, Miss., Sept. 23, 1887.

[The Rule 2, referred to, is one which we have followed in practice for years with great satisfaction. When accompanied with an explanation to the patient, or his nurse, that the medicine is safe in the dose prescribed, but dangerous if too much be taken, and that the word "poison" is only to prevent a mistake in taking it, the effect is to impress all concerned with the doctor's carefulness. We have never known it to work unfortunately.—EDS. OF THE REPORTER.]

Correction.

EDS. MED. AND SURG. REPORTER :

Dear Doctors :—Will you please state that the prescription found in my paper on "Vomiting of Pregnancy," in the REPORTER of September 24, should have included "Syrup. simp. q. s. ad. f $\bar{3}$ iv," making it read :

R Potass. nitrat.,
Potass. chlorat $\bar{a}\bar{a}$ $\bar{3}$ j
Ant. et potass. tart. gr.j
Tr. ferri chlor. f $\bar{3}$ iv
Syrup. simp. q. s. ad. f $\bar{3}$ iv
M. S.— $\bar{3}$ j every four hours.

Very truly yours,

Benezette, Pa. JAMES E. FREE, M. D.

NEWS AND MISCELLANY.

Native Medical Practice in Syria.

Dr. Ira Harris, missionary in Tripoli, Syria, writes the following interesting letter to the *Albany Medical Annals*, August, 1887 :

You have no idea of the immense amount of work a medical missionary has to do in this country, of the droves of people who flock to the dispensary and with him on his tours over the country. It would require an iron man to do all the work. When I am in Tripoli, I refuse all the medical cases I can, devoting myself as much as possible to purely surgical cases, of which I have many.

In this limestone region we have many cases of stone. I agree with Dr. Vander Veer that supra pubic lithotomy will never compete favorably with lithotripsy. I prefer the lateral operation. I have removed some large stones, and have seen no serious symptoms follow. In all my stone operations I have only lost one case, and this one died because his people did not give him proper nourishment in my absence.

A few months ago I visited a large village among the Nusairiyeh. The village barber called on me. These men not only ply the art of removing the hair from their customers' chins and heads, but they remove various quantities of blood from their bodies; the more ill or weak they are, the greater the quantity that is removed. They are also dosers of castor oil and sulphate of magnesia, no matter what the disease may be.

This man seemed to be very much interested in the operation of removing stone from the bladder, and in the various instruments I used. After the operation was completed, he said he liked his way best. "What do you know about removing stone?" I asked. "Oh, a little; I have removed over two hundred in ten years," was the reply. I

was inclined to doubt this statement. The man called to a boy to bring the smallest box of stones he could find in his house. The lad soon returned with a box containing sixty-three stones, which he spread on the floor before us. The barber's face shone with pleasure at these evidences of his skill. The fruit was before us, even if the patients did not all recover from their removal. There were all kinds and sizes, uric acid and oxalate of lime calculi being the most numerous. Some of the latter were of immense size. They showed by their broken spines and battered appearance the efforts used in their extraction.

When I saw the stones, I knew I had the pleasure of meeting one of those professional "Arab stone extractors" I had read of in books. In response to a request to tell me the technique of the operation, he kindly did so. He was very familiar with the symptoms of this disease, gave me all signs, etc.

When he suspected stone, he passed his finger up the patient's rectum; sometimes his whole hand, and felt for the stone. When he was satisfied of the presence of the calculus, he would again place the patient in the usual position, having five or six men to hold the patient; no anæsthetic was given. The operator would again pass his finger up the rectum behind the stone, bringing it up against the perineum; then with a knife, curved at the upper two-thirds, he made an incision in the median line upon the stone. If the stone was small he would remove it with his finger; if large, he would pass behind the stone a hook and drag the stone away. The knife and hook were of the rudest character, made of an old file.

I asked him if he lost many patients after the operation. He replied that many died of exhaustion, but that he never lost a case of hemorrhage. Strange, when we think of the reckless way he plunged the knife into the perineum. The only thing that seemed to trouble him was the fact that the greater number of patients who recovered after the operation suffered from incontinence of urine or had a fistula. The people have had the utmost confidence in him, and were willing to suffer all the complications following his rude way of operating to be relieved of their misery.

Since the time I saw this man he has complained that I get all the stone cases, "all because the American doctor never loses a case by death, and all come home and make urine from the natural passages and at regular intervals." The principal reason for their coming to me is not so much the suc-

cessful result as it is the removing of the stone without pain. They have a supernatural reverence for an anæsthetic.

In this country one in every five has tape-worm. This is owing to the custom of eating so much raw meat and defecating in the open fields. Nothing disgusts an Arab so much as to see "Franks" use a house (water closet). They are in the habit of going up some unfrequented street, if in town; if in the country, just where they happen to be. Fancy having a dozen or two chickens and several dogs following you if you happen to step aside from the beaten path in the direction of a place where the villagers usually go when they wish to relieve nature; these are the scavengers. I call to mind seeing several chickens gorging themselves with the links of tape-worm. Ever since, I will not eat chicken unless I *know* they have not been raised in a country village. When I first came to Syria, I prescribed for these people the western doses, and failed every time. I thought perhaps the drugs were to blame. I sent for fresh drugs. I used everything I had read of, with very little success, until, in desperation, I gave larger doses. In fifty-five cases I have succeeded in removing the head of the tape-worm, and thus relieving the patients permanently of their unwelcome tenant.

I will give you the history of a case that will give my present treatment. Mrs. A. had been suffering from tape-worm for twenty-five years. She said that she had not been free from pain during that time. She ate immense quantities of food; appetite never satisfied. Has taken medicine from many doctors, only resulting in passing yards of tape-worm. I gave her Felix mas in doses I had been taught to give. She passed eighty-two feet of worm; afterwards the symptoms were worse. Three months after she began to pass the links. I gave her fresh extract of pomegranate root. She passed seventy-nine feet of worm. I wanted to give her fresh extract, but she would not consent, saying I did not know how to treat tape-worm. I made up my mind that I would kill that worm or I would make the woman dreadfully sick. I waited some time for a change. In the meantime I got some fresh ethereal ext. Felix mas—something I knew was good. I ordered the woman to eat nothing but milk for three days. On the night of the third day I gave her eight comp. cath. pills; the next morning at daylight, Felix mas $\mathfrak{z}$ iss; in half an hour a second $\mathfrak{z}$ iss; one hour after, castor oil, $\mathfrak{z}$ j. Twenty minutes after, I had the pleasure of seeing a quantity

of something that was once a tape-worm, now looking as if it had been used pretty roughly. The head was found after some search. With the removal of the head, all symptoms disappeared.

Since then, I have treated fifty-four cases, and have given in the greater number $\mathfrak{z}$ iij of the drug. There seem to be two conditions to insure success—a few days of milk diet and a brisk cathartic, followed by large doses of *fresh* male fern. I have never seen any bad results following the use of this drug given in these doses. If I should have a case that did not succeed after the above treatment, I would give a third $\mathfrak{z}$ iss sometime during the day. Of course, I would watch my patient for any ill symptom. But I do not apprehend any necessity of giving more than $\mathfrak{z}$ iij of the drug, providing the diet has been strictly followed out and the drug is *fresh*.

Two weeks ago I visited a large village, where I found many cases of granular lids and other eye diseases. They told me of an "eye-wash" used here, made as follows: Take one onion, bruise it well, then add one tablespoonful of salt; mix thoroughly, then add eight ounces of water. Sig. gtt.x in each eye daily. I asked them if much pain followed the use of this remedy. They replied: "Of course; it would be of no use if it did not give pain."

It is fearful to see the quantity of nitrate of silver (they call it the stone of hell), sulphate of zinc and sulphate of copper that these people put in their eyes. I wonder that every person who has ever had anything the matter with his eyes is not blind, when we see the eye-drops they use.

Opium-Doctoring in Smyrna.

It is said that within the last few years the adulteration of opium has been pursued at Smyrna in a far more systematic manner than formerly, and the practice threatens to grow still further. About five years ago certain opium-dealers in Smyrna, after sundry experiments in kneading together old and new opium by applying vapor heat, secretly purchased machinery in England. By the aid of this apparatus they were able to mix opium on a considerable scale, and the product thus manufactured at first found a ready sale on most European markets. At present, it is said, nearly all Smyrna dealers who are in the habit of making firm offers to the principal markets are in possession of the kneading machinery, and turn out an opium consisting partly of the new product and

partly of two or three old juice. The opium thus produced has been exported in large quantities to the United States in order to save import duty; but probably this outlet will be closed in future, for the Customs authorities at New York have recently decided that no opium containing less than 9 per cent. morphia shall be allowed to enter the United States, and that shipments which do not come up to this standard must either be destroyed or re-exported within six months. The Chinese refuse to purchase the Smyrna mixed opium, and orders from Cuba or California frequently contain the stipulation that no kneaded opium shall be shipped. Consignments forwarded to Hong Kong and Singapore have also been returned to Smyrna. In England the Smyrna mixed opium is not unknown, but is not so largely sold here as on the continent. It is stated that, though in kneading opium by means of machinery, it is quite possible to bring the mixture up to a certain definite standard of morphia, experienced opium-buyers are always able to detect the compound.—*Chemist and Druggist*, August 27, 1887.

Prohibition.

In the *New Princeton Review* for September, 1887, Gov. Colquitt, of Georgia, in "Some Plain Words on Prohibition," makes an eloquent appeal for prohibition in the land, because it "has reason, religion, refinement, good order, and peace for its advocates and champions." He cites the case of Atlanta as a refutation of all objections.

A Tribute to Physicians.

Robert Louis Stevenson dedicates his just-published volume of poems, *Underwoods*, to "a few out of the many doctors who have brought me comfort and help." He adds: "There are men, and all classes of men, that stand above the common herd: the soldier, the sailor, and the shepherd not unfrequently; the artist rarely; rarer still the clergyman; the physician almost as a rule."

The Health of Jews.

Popular credence has always conceded to the Hebrew race the possession of great wealth; and while much has been said and written upon this subject, little attention has hitherto been directed to the general healthfulness which prevails among this community. The latter subject, however, has not been entirely neglected, for we read that in the Middle Ages much

prejudice was excited against the Jews on account of their comparative immunity from epidemic diseases, and now-a-days ardent advocates of the total abstinence programme point with gratifying satisfaction to the sobriety which distinguishes the descendants of Abraham, among whom, as a race, the evil effects of alcoholic ingestion are supposed to be seldom seen. There are, of course, exceptions to every rule, but, if in this respect the Jews living in this country can be entitled to the honorable position which is accorded by the teetotal orators, we must admit that, in the midst of so much temptation, they merit some commendation for their abstinence. However, whether the fact can be attributed to their sobriety or to their exceptional prosperity, it is nevertheless somewhat surprising to learn that there can be little doubt that, as a whole, the Jews are hardly less fortunate in their physical condition than in their worldly circumstances, and that the descendants of Abraham are freer from fleshly ills than the common sons of Adam. A recent writer, at all events, has been at some pains to ascertain this fact respecting the Jews in the German Empire. He states that in Prussia from 1822 to 1840, the Jews increased by $3\frac{1}{2}$ per cent. more than the ordinary population. In the town of Fürth, where the average duration of life among Christians was twenty-six years, among Jews it was thirty-seven years, and in Frankfort he observes that the average longevity of the Jews is eleven years in excess of that of the Christians. He also adduces statistics pointing to the same fact respecting the town of Algiers. One of the most remarkable instances of Jewish immunity from epidemics occurred about two years ago. During the prevalence of the cholera in the south of France, out of the large Jewish population which dwelt in the infected districts only seven persons succumbed to the disease. The Jewish race is one of characteristics; it is characteristically wealthy; characteristically, as we must believe, healthy, and characteristically—but we need not proceed further in this comparison, since various other features of the favored race will at once present themselves to the mind. Perhaps the most unaccountable side of the Jewish human nature displays itself in the presence of disease; for Jews can scarcely, as a rule, be said to be satisfactory patients. When the malady from which the patient is suffering resists the skill of the attending physicians or surgeons the utmost alarm begins to spread through the household, and a degree of lost-headedness comes

to be established from the patient downwards, which to sober-minded Gentiles is perfectly inexplicable. Whatever the cause of this condition of things may be we can well believe in its reality, for in cases where recovery follows, and the dire catastrophe has been averted, with justice it can be said that gratitude takes the place of consternation, and the family attendant may make his mind at ease regarding his fees.—*Medical Press and Circular.*

Anxious for Students.

Dr. Frederick H. Gerrish, Secretary of the State Board of Health of Maine, read a paper before the American Academy of Medicine, September 3, upon the requirements of a preliminary education by medical colleges of the United States, an investigation of which was undertaken on behalf of the Academy. Among the devices adopted to secure the information upon which the report is based was the following:

A little girl, 8 years old, whose handwriting, though fair for her age, betrayed the immaturity of the writer, made applications in various forms and over fictitious names for admission to the different medical colleges. She confessed in each case, as she truthfully could, her lack of proficiency in natural philosophy, Latin, or some one of the natural sciences, a knowledge of which, according to the college prospectus, was required as a preliminary to admission. To their credit, the report says, one-half the replies indicated a purpose on the part of the institutions from which they came to rigidly adhere to the requirements of the advertisement and advised the applicants in various forms not to attempt the study of medicine until the proper foundation has been laid. But from the other half quite a different condition of affairs was developed. Expressions from several of the replies from this class of institutions were read and heartily laughed at by the assembled doctors. The following were a few of these expressions:

"Our examination is not difficult. No one has yet failed to pass."

"We do not propose to make entrance to our institutions a bugbear."

"Our preliminary examination is very simple."

"If you have a good common school education, as I see you have from your letter, you will experience no difficulty in entering."

"Natural philosophy is not required, except as a suggestion in the line of a liberal education."

"You need not be hindered by fear of the examination."

"The preliminary examinations are not difficult, and no deserving applicant is rejected on account of not being able to pass them. Call and see me when you are in the city, and I will fix it so you can enter."

"Never mind about the natural philosophy; that will be all right."

Dr. Gerrish's conclusions are as follows: "It appears that about one-quarter of our medical colleges make no profession of requiring any real preliminary education in their pupils; a few hint vaguely at the desirability of some knowledge, and about two-thirds announce an examination or its equivalent, as shown by a certificate. Of these the last half adhere to their pledges, and the other half evidently do not mean what they say. The actual standard is extremely low. A very few schools require a preliminary education which is somewhere near an equivalent for medical study. A considerable number exact a knowledge of the ordinary grammar school studies with a mere trifle of natural philosophy; the most will admit any male human being who can write an intelligible letter of inquiry and pay his tuition fees."

Opium Gathering.

"The opium gathering begins in January or February," said an East Indian (*New York Sun*.) "The poppy flowers have then given way to the seed pods, which are lanced in the afternoon. The thick gum, the opium, exudes from the cut made in the pod, and at daylight the entire family of a ryot are astir in the fields, scraping opium from the pods, the incisions being carefully closed again by rubbing the finger sharply up and down on the cuts, which glues them shut. If carefully treated the pods will respond liberally to six lancements. The opium is at first placed in brass vessels, and the dew that may adhere to it is drained off. Then it is kneaded like dough until it is at the proper consistency, when it is packed in new earthen jars and is ready to be carried to the weighing stations. The order to fetch in the year's crop of opium is generally given early in April, and that is the most interesting season of the year to the ryot and his family. Each farmer is notified that on a certain day he must be at the weighing station of his district for the testing and weighing. An entire village, men, women and children, join in joyous procession when this notice is received, and, laden

with the jars of opium, start for the destination. They travel only at night, as the heat of the sun is so great at that season of the year that the journey would be unendurable. All day they lounge in the groves and shady lanes, feasting and joining in various recreations. These wayside camps of the opium villages are picturesque sights to the traveler through these provinces. When a group arrives at the weighing station they are arranged in long lines before the examiner, who examines the opium of each one and marks the quantity and weight of each jar with a piece of chalk on the side of the jar. The examiners are experts, and can tell by the feeling whether a sample of opium is adulterated, but they put it to chemical tests as well. After the opium is all weighed and tested the different farmers receive the amount their yield entitles them to, less the government advances, and the gay procession takes up its march for home. The opium is forwarded to Calcutta in boxes, known as opium chests, and the insidious drug is ready to be sent on its mission of blessing to many and of misery to many more."—*West. Druggist*, August, 1887.

Items.

—Dr. Brouardel has called attention to the possibility of error in chemical examinations of human discharges, through the fact that ptomaines give color reactions that closely resemble those produced by the vegetable poisonous alkaloids.

—Dr. Gross describes his experiences abroad in detail in his book, and some of them are full of interest. Such are his meeting with Dr. Pusey, his breakfast with Sir Henry Holland, where he met Froude, the historian, and his conversation with an English lady at a dinner party in London. When he told her "that in the garden of one of my sons-in-law, near Baltimore, there were at that moment twenty-six culinary vegetables growing side by side," she threw down her fork, raised her eyes like a duck in a thunder-storm, and almost audibly said: "That is not true."—*Philadelphia Press*.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from October 2, 1887, to October 8, 1887:

Capt. Wm. R. Hall, Assistant Surgeon, from David's Island to Ft. Custer, Mont.

Capt. C. E. Price, Assistant Surgeon, from Ft. Custer to Ft. Du Chesne, U. Ter.

First Lieutenant Wm. N. Suter, Assistant Surgeon, from Washington Bks. to Ft. McKinney, Wyo.

Capt. D. Weisel, Assistant Surgeon, from Ft. McKinney to Ft. Sill, Ind. Ter.

Major S. M. Horton, Surgeon, from Ft. Riley to Ft. Adams, R. I.

Major D. Bache, Surgeon, from Ft. Adams to Ft. Riley, Kan.

Major J. P. Kimball, Surgeon, from West Point to Ft. Elliott, Tex.

Capt. R. C. Newton, Assistant Surgeon, from Ft. Elliott to Ft. David's Island, N. Y. H.

Major C. L. Hirmann, Surgeon, from Ft. Ontario to West Point, N. Y. S. O. 232, A. G. O., Oct. 5, 1887.

Capt. E. C. Caster, Assistant Surgeon, leave of absence further extended fifteen days. S. O. 231, A. G. O., Oct. 4, 1887.

First Lieutenant J. M. Cabell, Assistant Surgeon, relieved from further duty in connection with the competition of "Team of Distinguished Marksmen," at Bellevue Rifle Range, to take effect Oct. 1, and will return to his station, Ft. Omaha, Neb. S. O., 95, Dept. Platte, Sept. 27, 1887.

First Lieutenant J. M. Cabell, Assistant Surgeon, will be relieved from duty at Ft. Omaha, assigned to temporary duty with Battalion Sixth Infantry in the field.

First Lieutenant W. C. Borden, Assistant Surgeon, will be relieved by officer commanding troops, upon arrival of Assistant Surgeon Cabell, and will return to his station at Ft. Douglas, Utah. S. O. 98, Dept. Platte, Oct. 1, 1887.

Changes in the Medical Corps of the Navy for the week ending October 8, 1887:

Assistant Surgeon Wm. Martin, detached from Hospital, Norfolk, and granted sixty days' leave.

Medical Inspector N. L. Bates, detached from Naval Dispensary and to Examining and Retiring Boards.

Surgeon A. F. Price, ordered to the Naval Dispensary, Washington, D. C.

Surgeon J. R. Waggener, ordered to the Receiving Ship, "Minnesota."

Surgeon Paul Fitzsimmons, detached from "Minnesota" and to the "Morian, Oct. 15.

Assistant Surgeon Louis W. Atlee, detached from Receiving Ship "Vermont" and to the "Morian," Oct. 15.

Passed Assistant Surgeon W. H. Rush, detached Coast Survey Steamer "Blake" and to the Navy Yard, New York.

Assistant Surgeon T. A. Benyhill, detached from "Minnesota" and to the "Blake."

Surgeon M. C. Drennan, detached from Naval Academy and to await orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ended October 8, 1887:

Fairfax Irwin, Passed Assistant Surgeon, granted leave of absence for twenty-five days, Oct. 5, 1887.

John Guitéras, Passed Assistant Surgeon, granted leave of absence for seven days, Sept. 28, 1887.

Seaton Norman, Assistant Surgeon, upon expiration of leave of absence to rejoin station, New York, Oct. 4, 1887.

ORIGINAL DEPARTMENT.

SPECIAL ARTICLE.

THE CHOLERA AT THE PORT OF NEW YORK.

The arrival of the steamship "Alesia" in the port of New York a few days ago with Asiatic cholera on board, has occasioned considerable alarm on account of the possibility of the disease spreading in this country, although late in the season. Past experience with epidemics of this disease has shown that although a temperature as low as the freezing point, even for a few hours at a time, such as occurs during nights of frost, is usually sufficient to arrest the spread of the epidemic under ordinary circumstances, yet the disease has been known to pass through the winter under the intense cold of northern Russia; and there are quite numerous instances of epidemics lingering through the winter in other countries where the cold is far less intense. The possibility of the spread of an epidemic from the few cases of cholera kept at the New York quarantine station therefore offers sufficient cause for the interest which has been taken, not only by the general public in and around New York, but also by the medical profession throughout the country, particularly by those members whose official positions or lines of study naturally cause them to give particular attention to any epidemic disease which may seriously threaten the public health. It is in recognition of this fact that the following brief account of Dr. E. O.

Shakespeare's recent visit to the New York quarantine station is given to the readers of the REPORTER.

The object of Dr. Shakespeare's visit was three-fold: First, to learn whether, or not, the disease was genuine Asiatic cholera, as it had been reported to be; second, whether the comma-bacillus of Koch was to be found in the dejecta or intestinal contents; third, what measures were being enforced to prevent the spread of the disease beyond quarantine. Through the courtesy of Dr. W. H. Smith, the health officer of the port of New York, Dr. Shakespeare was permitted to visit that station, and allowed to make any observations which he desired.

The steamer "Alesia," with a French captain and crew, sailed from the port of Marseilles on the 30th of August last, laden mainly with baled wool, for the port of New York. On the 2nd of September the steamer touched at the port of Naples for the purpose of taking aboard some 550 or 600 Italian and Sicilian emigrants, who were booked as steerage passengers. The next day, the 3rd, the steamer not having taken aboard any provisions, water or merchandise at Naples, again put to sea with the intention, on the part of the captain, of stopping at the port of Palermo, on the island of Sicily, for the purpose of taking aboard some forty additional steerage passengers; but, at the earnest remonstrance of the ship's surgeon, an apparently intelligent physician of Marseilles, based upon the danger of taking cholera aboard, the disease being then very widespread throughout that island, the captain abandoned his original intention, and pro-

ceeded direct for New York. There is good reason to believe that there was no cholera in Marseilles at the time or previous to the departure of the vessel; but the American Consul at the port of Naples, Mr. Edward Camphausen, inserted a note in the clearance bill of health, stating that cholera was then prevalent in and around the City of Naples, and had been so for the preceding five weeks. Many of the emigrants taken aboard at Naples were taken from the Island of Sicily, but they had remained for some time in the city of Naples before sailing, and in view of all the circumstances, it is impossible at this time to say whether the cholera, which subsequently broke out on the steamer, was originally brought from Sicily or from the city and suburbs of Naples itself. As has been stated, the steamer left the port of Naples, bound for New York, on the 3rd of September. The first case of cholera recorded in the notes of the ship's surgeon, under that name, occurred on the 12th, that is, nine days out from Naples. Subsequently to that date new cases were constantly developing during the remainder of the voyage, and, as is now well-known, the ship reached the quarantine station in New York flying the yellow quarantine flag, and with cholera still on board.

The first subject of investigation to which Dr. Shakespeare directed his attention was the record which the ship's surgeon had kept of the health of the passengers and crew during the whole of the voyage. It was found that upon the fifth of September, two days out from Naples, a child was seized with symptoms, which, according to the recorded notes, and in view of the subsequent outbreak of cholera, may very easily be taken to have been a mild case of cholera, unrecognized by the ship's surgeon. Again, on the tenth of September, that is five days later, there is a record of another attack, this time the ship's baker himself, which gives strong ground for the belief that this patient was really suffering with decided symptoms of cholera, although the surgeon failed to consider it such, and noted the attack as "caused by fright or violent anger." The symptoms recorded in this case are mainly cerebral congestion, great oppression and difficulty in breathing, violent vomiting, some purging and cramps. Thus it appears to be extremely doubtful that the first case of cholera aboard this ship really occurred on the twelfth of September, nine days after leaving port, and consequently after a period of incubation lasting that length of time. Indeed it is highly probable, in view of all

the facts and of the usual extremely short period of incubation of cholera, that the disease made its appearance as early as the second day of the voyage, and continued its presence until New York quarantine was reached, although it was not recognized until the twelfth of September.

At the time of Dr. Shakespeare's visit to the ship the process of disinfection and fumigation was going on. The steerage, the saloon deck and the fore-castle had already been cleaned up and thoroughly washed with a solution of corrosive sublimate—one part to four thousand; and the cargo was being exposed to the action of the fumes of burning sulphur placed in a large metallic pot in the lower hold, the upper hatches of the main deck being battened down, and the hatches of the intervening decks off. In addition to this the Health officer was devising some means of subjecting the interior of the vessel to the action of super-heated steam.

The emigrants had previously been removed to Hoffman Island, a small island in the lower New York Bay, five miles from the boarding station, which latter is located in the Narrows at the entrance of New York harbor. The crew and three of the saloon passengers remained upon the steamer. There is another artificial island within a mile of Hoffman Island, devoted to the uses of a hospital. This hospital is under the immediate direction of the resident superintendent, who is not a medical man, and the patients kept there are attended to by a young man who has attended two courses of medical lectures, but has not received his diploma as a doctor of medicine. There is no resident physician upon this island, which is known as Swinbourne Island.

Hoffman Island is used as a station of observation, is about four acres in area, and has upon it three large, substantial buildings, one of these devoted to heating, cooking and washing, another building used for storage and disinfection of baggage, and the last, a large two-story building, intended for the use of people under observation. There is no resident physician stationed at this island, and the 550 or 600 immigrants kept under observation at this time are controlled and watched day and night by some five or six hired attendants of the class of laborers and watchmen.

The mode of disinfecting the baggage was as follows: There are two disinfecting rooms 15x30 feet, with one or more windows in the corners of the large store-house above mentioned. These rooms are separated from the rest of the building by a board partition,

which is nearly air tight. The baggage is unpacked, articles are separated and hung up on lines which cross the rooms in various directions. These articles are exposed to the fumes of burning sulphur, in such a way that the sulphurous acid gas comes in direct contact with the whole texture, and thus thoroughly destroys any living substances it may contain.

The 550 or 600 immigrants upon Hoffman Island are watched by the hired assistants already mentioned, and cases of diarrhœa, or if genuine cholera developed during the course of the twenty-four hours among them, are reported to the Health Officer at the time of his daily or semi-daily visits to this island. They are then removed to the hospital on Swinbourne Island, and placed under the treatment of the medical student above mentioned. The medical treatment of these patients, as well as that of those who may develop symptoms of illness on Hoffman Island, of course, is under the direction of the Health Officer, who is a distinguished, thoroughly capable and wide-awake physician.

At the time of his visit to Swinbourne Island, Dr. Shakespeare obtained cultures and made examinations, in other ways, of the stools of the patients who were suffering with the disease. The symptoms were undoubtedly those of Asiatic cholera, and in some cases of an extremely rapid type. No difficulty was found in isolating the comma-bacillus of Koch, and making pure cultures of it in the usual manner from the stools of the patients.

These observations are entirely in accord with those which Dr. Shakespeare has made concerning the same disease in Italy, Spain and India, and they confirm the opinion which he had already formed, that through the recognition of the comma-bacillus of Koch in the dejecta of suspicious cases, we have a certain and easily applicable means of diagnosing Asiatic cholera from other affections with which it might, under some circumstances, be clinically confounded. The Health Officer seemed to be thoroughly alive and appreciative to the necessity of enforcing the most efficient measures for the destruction of the cholera poison, which may be contained in the soiled clothing and bedding of the passengers and crew, or lurking around the ship. In view of the lateness of the season, the measures appear to be such as warrant the belief that the disease will not be allowed to escape beyond its present limits. With abundance of funds for the purpose of protection of

the public health, we have not the least doubt that the country would be absolutely safe at the present time from an epidemic of cholera. The only source of danger which at present seems to exist is to be charged to the niggardly spirit with which funds for the provision of proper equipment and running of the hospital and other buildings on Hoffman and Swinbourne Islands, has been made by those who are responsible.

COMMUNICATIONS.

TREATMENT OF TYPHO-MALARIAL FEVER.

BY GEO. Y. WOODWARD, M.D., OF LOUISVILLE, MISSISSIPPI.

This form of fever, which has prevailed pretty extensively in this country for the last few years, does not seem to be well understood by the profession; hence there is a great variety in its treatment, with unsatisfactory results in many cases. Although often regarded as typhoid fever, it differs very much from it, and requires a different treatment. In typho-malarial fever, as in typhoid, there is usually debility, nervousness and loss of appetite for a week or more before the disease is developed. The tongue is sometimes thin, and coated brownish, with red tip and edges; sometimes it is large and flabby, with little coating. The bowels are usually constipated, and there is pain and soreness over the liver; sometimes over the bowels also. Most of the cases this spring and summer have commenced with a "cold"—sore throat and more or less cough. The temperature ranges from 100° to 105°, and is usually lowest in the mornings. The bowels are generally harder to move than in typhoid fever, and diarrhœa is very seldom present; hence less care is necessary in using purgatives.

I treat the disease as follows: I give calomel and Dover's powder, two grains each, repeated every two hours until three doses are taken. This is followed in six or eight hours with a dose of castor oil or some other mild cathartic. I then give about 10 grains of sulphate of quinine every two or three hours until three doses are taken, each day for the first four or five days. I also use tincture of gelsemium in doses of from 10 to 18 drops every two or three hours according to the fever, and sponge the patient

with tepid or cold water two or three times a day.

If this treatment do not abate the disease, I stop the sulphate of quinine and use:

R	Carbolic acid.....	ʒj	℥j
	Glycerine.....	ʒj	
Mix and add:			
	Iodine.....	grs. xx	
	Iodide of potash.....	grs. xxx	
	Water.....	ʒj	

Mix. Dose, 10 to 12 drops in water or sweetened water three times a day.

I have great confidence in this mixture in treating typho-malarial fever, as well as typhoid fever. It should be kept up daily until the fever gives way. The temperature should be kept down by bathing and the careful use of tincture of gelsemium. Mild purgatives should be used to regulate the bowels, and it is well to use calomel and Dover's powder in small doses about once a week. Unusual symptoms must be met when they arise, as indicated. I prefer a milk diet. Pure, sweet milk, ice cold, is good. Some butter-milk, when desired, is not objectionable. In the later stages of the fever I add a raw egg to the sweet milk—say to six ounces—and mix well. The patient hardly ever detects the egg in the milk. Other diet can be used, always with care. Soups do very well, but are more likely to disagree with the patient and to increase the fever.

If there is much liver trouble, I apply a blister; if soreness over the bowels, I have them rubbed several times a day with some stimulating liniment.

The thermometer is necessary in the proper management of this fever, as the skin is often moist and cool when the fever is high. Sometimes profuse perspiration is present; hence the need of a thermometer.

When convalescence begins, care should be used not to expose the patient to a draught, especially if the weather is cool or damp; otherwise a dangerous sore throat may be induced. I have known two young ladies to lose their lives from exposure after convalescence had set in.

The above treatment properly carried out will generally cure a patient with typho-malarial fever. The tongue does not generally become dry while using the carbolic acid and iodine mixture; should it do so, spt. turpentine may be used with the mixture. If the tongue gets pale, with a white coat, 15 drops of aromatic sulphuric acid may be given two or three times a day.

SULPHATE OF MAGNESIA IN ABDOMINAL DISTENSION AND PERITONITIS AFTER LAPAROTOMY.

BY CHARLES B. PENROSE, PH.D., M.D.,

Surgeon to Out-patient Department of the Pennsylvania Hospital.

The administration of a purgative for the relief of the abdominal distension and peritonitis which sometimes follow laparotomy, was first advised by Lawson Tait. The treatment is also advocated by Greig Smith and by other surgeons abroad and in this country. There is at the same time a strong tendency among many physicians to adhere to the routine practice of administering large doses of opium as soon as any symptoms of peritonitis are manifest.

The abdominal distension which follows laparotomy is due to paralysis of the muscular coat of the intestine. In the simplest cases this distension lasts but a few days, and is caused by the diminished tonicity of the intestine muscles, from exposure, manipulation or relief from intra-abdominal pressure. In other cases, it may precede or accompany peritonitis, and the muscular paralysis is caused by the inflammation of the serous covering of the intestine.

The results of abdominal surgery show that it is not necessary to paralyze the intestinal track further by the administration of opium. The danger of moving the bowels after exposure of the peritoneum has been much exaggerated. It seems probable that the peritoneum is subjected to, at least as much irritation from the tension and movement caused by the distending gas, as it would be from any peristaltic motion of the muscles of the intestines.

A free, watery purge encourages peristalsis and the escape of gas. It depletes congested peritoneal vessels, and probably drains off, through the intestines, serum which was contained in the peritoneal cavity. The diminution in the quantity of the serum discharged from an abdominal drainage tube is often very marked after the administration of a free purge.

The choice of the purgative depends somewhat upon the nature of the case. When there is excessive vomiting it may be necessary to employ small, frequently repeated doses of calomel. In most instances, however, there is no better purgative than sulphate of magnesia. It produces large serous evacuations and no intestinal irritation.

I have used sulphate of magnesia in several cases of abdominal distension and peritonitis following laparotomy, and in no case have I found it necessary to give opium.

The following case illustrates the value of this plan of treatment :

A woman, upon whom I operated for double pyosalpinx, developed symptoms of peritonitis on the second day after the operation. She had a chill, followed by great abdominal pain and distension; her pulse was 110, her temperature 99.5°. Her knees were drawn up, and the jarring, caused by motion in the room, provoked exclamations of pain. An ounce of sulphate of magnesia was administered in one dose. This produced four large serous evacuations during the next twelve hours. The drainage tube then became dry, and all alarming symptoms disappeared.

Occasionally the intestinal paralysis is too great to be overcome so quickly. In another case operated upon for the removal of a large dermoid cyst of the ovary, peritonitis appeared upon the third day after operation. The discharge from the abdominal drainage tube became very profuse. The abdomen was much distended and tender. The pulse ranged from 120 to 140; the temperature from 97.5° to 100.5°. The respirations were over 40 per minute. The tongue was coated, and for two days there was hiccough and bilious vomiting. The venous congestion and abdominal pressure were so great as to cause large external hemorrhoids.

Large doses of sulphate of magnesia and frequent turpentine enemata were administered for several days. The enemata were retained for only a few minutes, and their rejection was followed by the escape of a small quantity of flatus. On the eighth day the bowels began to act. For 24 hours there was profuse watery diarrhoea. The discharge from the drainage tube ceased, the tympany diminished, and in a few days the hemorrhoids had disappeared. The abdominal distension decreased but slowly; and continued, to a slight extent, after the patient was able to leave her bed.

When there is simple abdominal distension gradually increasing and unaccompanied by other disturbance, small, frequently repeated doses of sulphate of magnesia produce speedy relief. The cases, however, in which the effect of sulphate of magnesia is most marked, are those in which it is administered at the onset of dangerous symptoms. When, on the second or third day after operation, or in some cases even later, alarming abdominal symptoms appear, the immediate administration of a dose of one ounce of sulphate of

magnesia will, in most cases, save the patient from further danger.

PUERPERAL MASTITIS.

BY A. E. CALKINS, S. B., M. D., BATH, MICH.

Since the discovery by Pasteur of the lactic acid ferment, all varieties of epidemic and contagious diseases have been carefully tested by the germ theory, in a more or less successful search for their positive etiology. In this way pelvic inflammations, puerperal complications, erysipelas, phlegmasia dolens and even scarlatina have been proved members of the same family, springing from a common parent, with a tendency to influence and modify each other. It is a species of correlation of diseases. The great advance made in pathology and its practical application in treatment since the writings of Sir James Y. Simpson, upon "The Analogy Existing Between Surgical and Puerperal Fevers," has never been surpassed in the history of medical science. The birth of the germ theory in 1857, with its unprecedented progress since, has demonstrated that these diseases are not simply analogous, but identical.

Mastitis occurring during the puerperal period, influenced by the same conditions and subject to the same causes, necessarily invited the scrutiny of bacteriologists and pathologists to its phenomena and causes. So very thorough has this investigation been conducted that we have a positive knowledge that certain forms of mastitis are produced by micro-organisms closely connected in relationship with those causing other puerperal inflammations.

Puerperal mastitis is confined by its definition to any inflammation of the functionally active mammary gland, occurring during and dependent on the puerperal state. When impregnation has taken place, reflex nervous excitation causes an increase in the mammary blood supply, cell and tissue organization and development becomes active; there is a physiological intumescence of the whole organ, fitting it later on, for the secretion of milk. The accumulation of this new secretion may extend and irritate the freshly formed tissues, and set up a pathological action involving one or more lobes. This stimulation will increase the quantity of milk secreted, bulging and sometimes bursting the fragile glandular vesicles, modifying their nutrition and stopping the secretion. The lining epithelial cells will be thrown off and destroyed,

exudations will be poured out, and may pass through the ruptured and weakened walls into the connective tissue. These exudations may retrograde and form abscesses, or be re-absorbed. It is very seldom that pus is formed in non-infectious mastitis. There has been no contact with the atmosphere, and there is then only the result of over-excitation, followed by over-secretion.

The most frequent appearance of cases is directly after labor, the majority within two weeks. We get a history of a sharp stinging or pricking sensation in one or both breasts, accompanied or followed by a decided chill, with marked elevation of temperature, and the presence of a very tender, painful and lumpy area in the gland. There is general malaise, with aching pains all over the body, especially located in the back and limbs, with headache and foul tongue, and indigestion. Local examination invariably exposes a fissured or abraded nipple, the key to its positive etiology. The microscope has demonstrated the cause of this form of mastitis to be a micro-organism, with many of the class characteristics of those producing all other puerperal diseases. Its clinical history fairly intimates this relationship. There is the same abruptness of onset, decided chill, malaise and rise of body heat, indicating the existence of pyæmia. The necessary requisites for septicæmia are also all present. The peculiar condition of the fluid constituents of the body after gestation has been completed furnishes one important factor. The circulation is then loaded with broken down and disorganized cells, blood corpuscles, and all the uterine residue resulting from a completed pregnancy. There remains an unsettled equilibrium and relation in the blood circulation and blood constituents. There are innumerable yet physiological alterations in respiration, assimilation and excretion, incident to the establishment of lactation. The presence of bacteria, in the lying-in apartments, clothing, etc., of the patient, has been frequently demonstrated. The lochial discharges are an unfailing storehouse of these micro-organisms, so that it is plainly evident that any wound occurring during the puerperal period is liable to infection by pus-producing organisms through the medium of the air and by direct inoculation from the lochia.

In infectious or phlegmonous inflammation of the breast, there invariably exists some fissure, contusion or wound, usually in the immediate vicinity of the nipple,

making free communication between the atmosphere and the connective tissue. This will terminate in shallow and deep-seated inflammations of all forms and kinds, as different tissues and organisms are united.

The bacteria accumulate, and, coming in contact with the secretion in the milk ducts, form colonies, stopping up the mouths of the ducts and distending them with milk. Lactic fermentation begins and their walls become congested and inflamed. Before the epithelium disintegrates, pus forms in contact with it and contaminates a more or less large portion of the gland. An interesting inquiry may be instituted as to whether infectious mastitis ever occurs from the direct communication between the gland and the septic poison in the uterus by means of the absorbents and the circulation. We have no reason to doubt its occurrence in phlegmasia dolens and general phlebitis. We get inflammation and induration of the inguinal glands in specific diseases, of the lymphatics in epithelioma, and metastasis in mumps. There are cases of mastitis that are explainable only by supposing some such absorption.

That it is a communicable disease I have no reason to question. An evidence of phlegmonous mastitis being identical with other varieties of puerperal sepsis is found in the fact that these abrasions of the nipple frequently act as the starting point in phlegmonous erysipelas.

About the only disease with which it can be confounded is a furuncle situated upon the breast, and particularly when it forms under the skin and close to the nipple. The boil matures and opens upon the surface, never into the gland tissue.

The treatment will be regulated by the cause of the complaint. If it be non-infectious in character, resulting from excessive secretion of milk, rest, support and the local application of belladonna and camphor will be beneficial. The application of cold in the form of ice-bags and evaporating mixtures meet the indication admirably. Dr. Hiram Corson considers them as almost infallible in aborting suppuration. The older treatment of drawing off the milk, either by the child or artificially, cannot be too strongly condemned. It further irritates the gland, increases its secretions, and in every way makes a bad matter worse. Lowered blood pressure decreases the secretions, and belladonna, aconite and tartar emetic are useful. Pulv. ipecac. co. quiets the pain, the ipecac. counteracting the opium as a cardiac stimulant. Pressure by means of adhesive straps or a light figure-of-eight bandage, lessens

pain, arrests secretion, favors absorption, and, when skilfully applied, gives efficient support.

If the inflammation extends to suppuration, a large poultice should be applied until "pointing" occurs, when the pus must be evacuated by free incision. The wound should then be dressed aseptically.

The management of the phlegmonous variety can be best studied under two heads. First, prophylaxis,—by protectives and antiseptics; and second, remedial,—with evacuants and antiseptics.

Prophylactic. The breasts should be daily exercised, and the epidermis of the nipple toughened by adequate manipulations and local applications, commencing from four to six weeks before the expected time of confinement. Exposing the gland to the air with gentle but firm massage, will develop its structure considerably. If the nipple is small and retracted, it should be pulled out and manipulated until it will protrude sufficiently for the child to seize and nurse.

Fissures may be guarded against by regular bathing with alcohol, bay rum, or holding in solution some astringent, as tannin or subacetate of lead. After parturition, for the first forty-eight hours, or until the maximum quantity of the secretion is reached, the child should be allowed the breast at regular intervals. Once in three hours is sufficiently frequent. During the intervals the nipples should be bathed with the astringent solution, taking express care that they are perfectly cleaned before and after nursing.

Remedial. If any abrasions have occurred, they will demand immediate attention. Two objects are to be aimed at, to destroy all resisting micro-organisms in contact with the wounded surface, and to protect the tissues thus injured from contact, so far as possible, with the atmosphere.

At the first dressing it is advisable to wash the wound with a 1-2000 solution of sublimate, and thoroughly wash the latter off in a few minutes. Then dusting of the part with the subnitrate of bismuth or the oxide of lead is required. The antiseptic need be used but once if the dry dressing be faithfully applied. Boracic acid ground with vaseline makes an elegant dressing to be applied between the nursings, and it has the advantage of acting as a perfect protective to the injured tissues, and is harmless to the child. As the secretions become more profuse, more frequent nursing of the child should be practiced, but at regular hours as near as possible, being careful not to permit

an over distension of the milk ducts by the secretion.

When phlegmonous mastitis has so far progressed as to make more or less of the gland hard, tender and painful, free incision is the only method of treatment for relief. It is not necessary then to wait for "pointing" of the abscess, but immediate opening of it is demanded. Then wash the wound thoroughly with the sublimate solution. If abscess cavities have formed, each one must be entered and disinfected. When the gland has become honeycombed with these cavities, make a large incision, and with the finger break down and remove all injured tissue, and bathe every part with the antiseptic. A drainage tube should then be inserted, and the wound dressed with antiseptic precautions, care being taken to afford suitable support for the breast.

The constitutional treatment need not vary much from what it is in other puerperal inflammations. Besides the arterial and nervous stimulants and tonics usually exhibited, the iodide of potassium with quinine and salicylate of sodium are prescribed with great success. Nourishment easily digested and assimilated should be supplied in abundance. Outdoor exercise in suitable weather, with indoor pursuits of a pleasing nature, can not be too freely urged upon those patients that have been too closely confined to city life or household pursuits.

—From official statistics it seems that there are 36,512 persons in France holding diplomas that permit them to exercise some branch of the healing art. Of this number, 2188 physicians, 1523 midwives, 762 druggists, and 548 herbalists belong to the department of the Seine, *i. e.*, Paris and its environs. The 2000 odd Paris physicians are divided into two classes, as they are throughout France—namely, those of the first class, or *docteurs en médecine*, and those of the second class, or *officiers de santé*. Both classes practice medicine, about the only difference being that the second-class physicians can not perform any important operation without the aid of a *docteur*. They are known as *médecins*, and they pass a very much easier examination than the *docteurs*. Their diploma only allows of practice in one department, and does not apply to all France, as that of the *docteurs* does. This is the degree usually given to foreign physicians who practice in this country.—*Corresp. N. Y. M. J.*, Aug. 27, 1887.

SOCIETY REPORTS.

CHICAGO MEDICAL SOCIETY.

Stated Meeting, June 6th, 1887.

The President, WM. T. BELFIELD, M. D., in the chair.

DR. FRANK BILLINGS exhibited an interesting collection of

Bacterial Cultures,

explained the mode of their culture, and gave the name and description of each bacterium. At the present time, he said, there are three comma bacilli that are well known: the comma bacillus of Asiatic cholera, discovered by Koch, the one discovered by Deneke in old cheese, and the one discovered by Finckler and Prior. Under the microscope these look so much alike that one would not dare to differentiate between them, but their growth in gelatine tubes is so characteristic that one can easily tell the difference. The cholera bacillus grows upon the plate in a peculiar granular colony, which does not make the gelatine fluid so quickly as the bacillus of Finckler and Deneke. Finckler's bacillus liquifies the gelatine from above downward. Those found in old cheese liquify gelatine in the same way, but less quickly; while the cholera bacillus grows in a characteristic funnel-shaped form. It is quite as important to know how to cultivate bacteria and detect the difference in growth, as to know how to differentiate bacteria with the microscope by their form and their reaction to the aniline dyes.

DR. LESTER CURTIS read a paper on

Calcareous Concretions in the External Ear.

His patient had a painful swelling in the external meatus of the right ear. He considered it an ordinary superficial inflammation of the meatus and directed instillation of a solution of morphine. The pain at once ceased, and in a day or two the swelling subsided, and the doctor supposed that the trouble had resolved, but a little swelling and tenderness remained. In two weeks there was a discharge of a drop of purulent fluid. He paid no more attention to the case until about a month after this, when the patient called and told him that she had that morning picked out several calcareous masses resembling lumps of old lime. On examining the ear I saw a red and indurated place about half way down the meatus, in the upper portion of the posterior wall. In the middle of this spot was a pit about as large

as the mass removed, and surrounding the pit a greater or less amount of a white granular substance which grated against the probe and was of stony hardness. I attempted to detach some of it with the sharpened end of the probe, but it was firmly adherent, and appeared to be infiltrated throughout the tissue, and I succeeded in getting away only a few small flakes. Besides this nothing unusual was detected in the ear with the exception of a slight redness of the posterior rim of the drum-head. The hearing was perfect. A slight feeling of irritation was noticed for some weeks, but gradually passed away. At present, so far as I can discover, the ear is quite normal.

DR. R. TILLEY reported a case of

Atheroma of the Left Coronary Artery, Resulting in Aneurism of the Left Ventricle.

The patient was a lawyer, 57 years of age. His previous life had been exemplary. He did not use tobacco in any form, and was temperate and methodical in all his habits. He was corpulent, although when young he was very thin. At the age of 30 he was declared to be dying of consumption. Recovery, however, seems to have occurred without medical assistance.

On the 20th of October, 1885, he was unable to leave the house and had wandering pains, not severe, over the chest extending to the left shoulder and down the left arm, sometimes reaching the wrist. He first called my attention to this, thus: "I don't know whether I want to follow a doctor's directions or not. I get occasionally flying pains over my chest and in my left shoulder, but on walking about a little I can make them disappear." As he always had a marked antipathy to medicine of any kind, and I did not expect greater benefit from anything I could suggest than that which he claimed from exercise, I told him to continue to use the method he had found successful, and report later. At this time I had no conception of the existence in his case of atheromatous coronary arteries, nor did I suspect that the wandering pains were associated with incipient angina pectoris.

About six weeks after the interview above referred to, an acute attack of difficulty of breathing, associated with severe coughing and anxiety of countenance, came on. From this time he did not leave the house except for short walks. The pulse at this time was 120, feeble but regular. Breathing very laborious. He could not lie down on his back or left side, and only for a short time on the right side. Cough was very troublesome.

No special symptoms referring to the alimentary canal were present. On percussion no perceptible enlargement of the heart or liver was detected; nor any definite abnormal sounds. The principal feature which I observed was that of *asystole*, the ventricles seemed to stop as though shutting down on a pledget of wool. I find that Constantin Paul refers to this symptom very definitely as associated with aneurism, or what he calls false aneurism, of the heart. It certainly struck me as the one striking feature of the case. There was at this time no *œdema*, no fever, no albumin in the urine.

Drs. H. A. Johnson and R. H. Babcock saw the case, and the former remained as consulting physician to the end. The various heart tonics, such as *strychnia*, *arsenic*, and *digitalis*, were used with no demonstrable effect except that when the *digitalis* was increased so as to diminish the frequency of the heart's action, the action became so tumultuous and incoördinate that it was deemed best to let it beat at the gait it found most convenient. In about a fortnight after the commencement of the acute attack, anginal pains became more prominent, and atheroma of the coronary arteries was suspected. There was no evidence, however, of any atheroma of any superficial vessels. From this date a bottle containing carbonate of ammonia and camphor became his companion, supplemented with small pellets of 1-100 of a grain of nitro-glycerine. The latter gave more satisfaction than the nitrite of amyl. The anginal pains were not at any time characteristic in severity, but the pallor of countenance and anxious expression were. Later on the feature of *asystole* was not so well marked. The feet exhibited, on several occasions, a tendency to *œdema*, but ten days before death it began to increase rapidly, and no remedies were found capable of removing it. The *œdema* extended gradually to the hips, abdomen, and chest, and about nine weeks after the acute attacks, while walking across the room, he fell dead.

The patient derived marked comfort from gentle exercise in fresh air. When the side-walks were covered with ice so that he could not possibly walk out of doors, he would wrap up and walk in a room with the windows wide open. Nitro-glycerine and carbonate of ammonia were the only remedies that gave him any appreciable relief.

At the autopsy the heart was found to be somewhat enlarged and all the valves competent. There was little or no atheroma except in the coronary arteries. One of these was almost completely occluded. Just

below this atheroma of the left coronary artery, in the wall of the left ventricle near the apex, an aneurism had developed. It was about the size of a large walnut. The wall of the heart in the thinnest part was only two millimètres thick. The aneurismal cavity was filled with blood, part of which showed signs of organization and part signs of disintegration. The clot was evidently formed at two different periods. There were no signs of chronic endocarditis, but some of slight chronic myocarditis.

In the present case, I think that the starting point was the diminished calibre of the left coronary artery, due to its atheromatous condition diminishing the supply of nutriment to the corresponding tissue, and thus producing the extreme thinness of the walls in the part supplied by the artery. The clot of blood was probably the result of the incapacity of the left ventricle to completely contract and expel its contents, and probably occurred in part at the time of his acute sickness, about nine weeks before death.

The presence of this clot of blood fully explained the characteristic sound which I clearly recognized at the first, and which I described as though the ventricle contracted on a pledget of wool.

DR. ROBERT H. BABCOCK, in opening the discussion upon Dr. Tilley's paper, said: It was my good fortune to see the patient to whom Dr. Tilley has referred this evening, and as it was a case of remarkable interest and there are several points illustrative of the peculiar symptoms due to atheroma of the coronary arteries, and also illustrative of the difficulty often of diagnosing the condition, I would like to refer to them.

The first symptom mentioned by Dr. Tilley as important was that of *angina pectoris*, and herein this case was peculiar; the pains were flitting and were relieved by gentle exercise. It was wholly characteristic, however, in that the pain extended to the left shoulder and down the left arm. That is the characteristic pain of *angina pectoris*, although there are so many deviations from it that *angina pectoris* frequently passes unrecognized by the general practitioner. There is a liability oftentimes to mistake *angina pectoris* for neuralgia of the stomach. I have under observation a case where the pain has been considered for years *gastralgia*, but it is without doubt *angina pectoris*, the arteries are atheromatous and there are characteristic cardiac murmurs which are due to the atheromatous condition of the valves. The pain of *angina* may sometimes be localized in the wrists. Dr. Sawyer once mentioned

to me a case in which the angina pectoris always manifested itself by a feeling of cord-like constriction about each wrist. There was, however, with this an attendant paleness of the countenance and anxiety, and the patient was obliged to stop in his tracks until the pain had passed. The pain in angina pectoris may extend through to the back, or up into the occiput, at other times into the right shoulder and down the right arm. It may also radiate into the abdomen and down the inside of the thighs. It is usually so severe that the patient has to stand still and wait until the pain passes by. In the case mentioned, the pain was relieved by gentle exercise, and that possibly may throw some light upon the question as to whether angina pectoris is always due to arterial spasm or not. If due to arterial spasm in all cases, it would seem as if any effort of the muscular system would increase the arterial resistance through contraction of the muscles, and thus make a greater demand upon the heart; in which case exercise ought to augment rather than relieve angina pectoris, particularly, if as Leyden is inclined to think, angina pectoris is really due to spasm of the coronary arteries, as well as to a general arterial spasm, resulting in temporary anæmia of the heart muscle. In cases where the paleness of the countenance would seem to confirm this theory, we find that remedies which produce arterial dilatation, such as the nitrite compounds, always give relief. In this case there is an apparent contradiction; not only did exercise afford relief, which would seem to indicate that contraction of the peripheral vessels had nothing to do with the production of the angina, but on the other hand, since nitro-glycerine gave relief, there must have been arterial spasm somewhere.

The diagnosis of this case was not as difficult as it might have been, owing to the peculiarity of the cardiac sounds, although none of us, I think, really expected to find coagulum in the left ventricle filling up the lower third of the cavity. I gave my diagnosis of degeneration of the left ventricle, with atheroma of the coronary arteries, because of the very peculiar character of the sound over the left ventricle, which Dr. Tilley has very aptly described. It was a toneless, muffled sound, as if the heart struck the chest wall through an intervening layer of cotton, while on passing the stethoscope from the left ventricle toward the right ventricle the first sound came out with its usual clearness and more or less of its booming quality,

and it was on that that I based my diagnosis. At the post-mortem examination, we found degeneration of both ventricles, more marked in the left than in the right. This case would probably be classified by Leyden as subacute. Leyden has treated this subject more scientifically than any other author, since generally the subject is treated in a desultory way under the various heads of chronic myocarditis, fatty degeneration, aneurism, rupture of the heart, etc.

Leyden would group together all the different expressions of the same pathological condition, that is sclerosis of coronary arteries and all conditions dependent upon that, and he considers it under one head—changes of the heart resulting from the sclerosis of the coronary arteries. He recognizes as acute cases those in which the patient is ill perhaps for a few moments or hours on days. The first symptom is often a sharp attack of angina pectoris, or an attack of great cardiac distress and oppression without positive pain, which Gairdner speaks of as *angina sine dolore*. In these cases the patient frequently first discloses that he has heart disease by falling dead in his tracks. In cases of atheroma of a small branch of the left coronary artery, usually the anterior descending branch, frequently we find a condition closely resembling the hemorrhagic infarctus, and the heart ruptures at that point; in acute cases death may be due to the rupture, although more often to failure of the heart. Subacute cases, of which this seems to be an example, run their course in a few weeks or months and we find a combination of changes from acute fatty softening to chronic fibroid change, and these patients generally suffer a good deal with angina pectoris. The chronic cases are those that last for years, sometimes fifteen or twenty, and the symptoms are those of cardiac weakness or progressive cardiac failure, and these patients may die suddenly or gradually. In these cases we generally find extensive myo-carditic changes with great thinning of the heart walls.

The treatment of these cases is of course a thing which interests us. It is very unsatisfactory; is merely palliative, and consists chiefly in the severe cases of rest, with cardiac tonics and stimulants. Of especial service in angina pectoris are the nitrite compounds, although Leyden rather protests against the use of nitrite of amyl and nitro-glycerine. He recommends the hypodermic injection of morphine, stimulants, such as ammonia and camphor, hot alcoholic drinks, and heat to extremities. The diagnosis has to be based, in most of these cases,

upon the history and symptoms of progressive or sudden cardiac failure, and if we can find evidence of atheromatous change in the peripheral vessels, the diagnosis is much easier. In auscultating these cases I have frequently found what seemed to me to be a peculiarity of the first sound. The sounds of the heart are nearly always described as free from murmurs, but since the booming quality of the first sound is undoubtedly due to the muscular element, and since the muscle of the heart is degenerated, the first sound takes on rather a short and valvular quality resembling very closely a second sound, so that frequently in these cases the two sounds appear to be two valvular sounds. Although I am not yet prepared to say that one can base a diagnosis upon such a condition as that, yet I am satisfied that in cases where there has been marked atheroma of the radial arteries, with symptoms of heart failure, I have heard just this condition of shortness and valvular quality of the first sound over the left ventricle, particularly when over the right ventricle the sound is more prolonged.

Dr. TILLEY said: I have nothing more to add except that I have known of two or three cases in which, after a hypodermic injection of morphine, in a condition of atheromatous coronary arteries, the patient has passed off very rapidly, and I would be chary of using

it, especially if I could obtain a satisfactory result from nitro-glycerine. The form of nitro-glycerine that I used were the elegant tablets of Fraser, so much more convenient than the alcoholic solution.

Dr. W. L. AXFORD presented the

Sac of an Aneurism of the Leg,

not very large or elaborate, but interesting because of its locality and the history of the case. Some time last November, a Bohemian came to the South Side Dispensary, having a little lump about as large as a walnut just above the internal malleolus. I could not get his history, as he could not talk English; all that I could make out was that it had been growing there about a year and pained him some. The skin was natural over the growth, which felt soft and fluctuated. I made up my mind that it was some kind of a cyst, and advised him to have it excised. On cutting down upon the growth I found at once that I had made a mistake, from the color of the sac, which was blue. One of my assistants said he saw a little artery spurt. I stitched up the wound and found I had excised the sac of an aneurism. It was about the size of a walnut when fresh. This case was peculiar, as there were none of the usual symptoms of aneurism; it was also peculiar in the large size of the sac compared with the size of the artery. The patient made an uninterrupted recovery.

EDITORIAL DEPARTMENT.

PERISCOPE.

Treatment of Congestive Headaches.

The following is a brief abstract of a paper by Dr. Glasgow, of St. Louis, and of the discussion upon it in the American Laryngological Association, reported in the *N. Y. Medical Journal*, September 3, 1887:

A few years ago I treated these cases with hot alkaline sprays, gently applied, and the use of hot fomentations, combined with the use of the usual constitutional remedies. This mode of treatment has not been altogether satisfactory, and during the past four years I have substituted for it the local abstraction of blood, for which I can allege unqualified success. In many cases there is experienced an immediate relief of the pain, and in all there is a sense of the loosening of the constriction. A simple bleeding may relieve the headache, or it may have to be repeated in a day, a week, or a month. I have seen but few cases which were not permanently

relieved by a bleeding repeated from two to six times.

To produce the bleeding no cut is required. The cavernous body is simply pricked, and the blood flows freely until the excessive tension has been reduced; then it ceases. The amount of blood drawn rarely exceeds one ounce; in many cases it is less than this, and in some cases a single drachm of blood removed will give the requisite relief. In cases of excessive congestion the flow will equal several ounces before it ceases, the quantity of blood being dependent upon the distension of the vessels, and this corresponds with the severity of the symptoms. From a normal membrane, or where there is no excessive vascular distension, scarcely a drop of blood will flow from a simple puncture of the membrane such as would produce a free flow in this pathological condition. In cases where the mucous membrane is thickened, a sharper puncture will be necessary to bring blood. A lance-headed probe may be best used in making the puncture, although a

sharp-pointed bistoury, or any pointed instrument, will answer. The probe has the advantage that it does not excite the apprehension of the patients, many of whom become nervous at the sight of a knife, and dread the idea of being cut.

Dr. C. C. Rice, of New York, in discussing this paper, said: The class of cases to which Dr. Glasgow has drawn attention is a very interesting one. My experience with regard to treatment is somewhat different from his, and I do not agree with him as to the pathology. I have seen a great many of these cases, as probably we all have, but they are not as a rule cases in which there is marked hypertrophy of either the anterior or posterior turbinated tissues. I have found that whatever hypertrophy did exist was over the middle turbinated bone, about three quarters of the distance back, and that it pressed against the septum. This condition is present so often that I have come to look for it in this class of cases. There has not been marked congestion or redness, but simply irritative contact, with consequent reflex pains and neuralgias. With regard to treatment, I have used the galvano-cautery instead of the knife, and I have not considered it an essential point to draw blood. My results have been good. I will cite an interesting case. A girl twenty years of age, who had suffered from most intense supra-orbital neuralgias and a sensitive condition of the nose, came to me a short time ago. For four years she had been obliged to plug her nostrils constantly with cotton so that no air could pass through them. I found nothing but an enlarged middle turbinated bone; there was no congestion. I made four or five punctures with the galvano-cautery needle in the turbinated bone, and the woman was cured. I think it is sufficient in the majority of these cases to make marked counter-irritation over the affected part.

Dr. Harrison Allen, of Philadelphia, said: I can confirm Dr. Rice's opinion. While I do not at all doubt Dr. Glasgow's diagnosis, yet it is evident this is a complex subject. It seems there is abundant evidence to show that the trouble came from the turbinated tissue, but all of my cases have been of the kind Dr. Rice has described. I have found that as a rule when the septum is deflected to the left, it is at the lower part; when deflected to the right, it is at the upper part. In the place last named, contact with the middle turbinated is likely to occur. The following case illustrates several facts in this connection. The patient had a complication of disorders. She had ocular and uterine

troubles, for which she had been treated by distinguished practitioners. Her headaches were of an exaggerated type. I resorted to repeated venesection of the turbinated tissues, giving temporary relief only. I then made an examination of the nostrils, introduced the finger, and separated the septum and turbinated tissues. There resulted very moderate bleeding. I found something which was very interesting. The lady was only thirty years of age, yet there was complete calcification of the triangular cartilage. The result was that her headache was completely cured. No recurrence took place. The procedure for overcoming the pressure effect may be carried out during the first stage of ether anæsthesia.

Treatment of Sea-Sickness.

Dr. Rebatel points out in the *Lyon Médical*, a method which he has often employed with complete success against sea-sickness. It stops the vomiting and even the nausea which nearly everybody feels on the sea. Patients say that they no longer feel their stomachs. This method consists in the employment of subcutaneous injections of atropine. Small doses are sufficient (gr. 1-50), repeated every seven or eight hours. The author has never noticed the least bad effect, except at times slight dryness of the throat. Sleep can be produced if desired, by adding a small quantity of morphine, but not enough to counterbalance the effect of the atropine. Administration by the stomach gives results that are much less certain.—*Union Médicale du Canada*, September, 1887.

Axillary Adenitis in Tuberculosis of the Lung.

Dr. Sanchez Toledo has devoted his inaugural thesis to this subject, which is absolutely new, Professor Grancher only having called attention to it in his clinic last winter.

The little girl who was the occasion of this study, having had pluerisy, came to the hospital very late in the disease with tuberculosis of the lungs and a large glandular tumor in the right axilla. Enlarged glands could also be found in the subclavicular and submaxillary region of the same side. Prof. Grancher compared with this case two others in which co-existence of tuberculosis of the lung and axillary adenitis had been noticed, and showed how it was natural to see a relation of cause and effect between the pulmonary lesion and the glandular. Therefore, said he, pulmonary tuberculosis can infect the axillary glands through the medium of the pleura, or by direct passage through lymphatics which proceed to

the axilla after traversing the thoracic wall, or through the medium of the subclavicular glands. It has, moreover, a certain importance in some cases with regard to diagnosis and prognosis. A glandular tumor might call attention to a still latent disease of the lung, the existence of which should deter the surgeon from removing the glandular tumor with the view of preventing general infection. "Henceforth," says Mr. Grancher, in closing his clinic, "every time a phthisical patient presents himself, do not fail to examine his axilla. Every time that you find an axillary tumor, do not neglect to auscult the lung."—*Concours Médical*, August 27, 1887.

Diphtheria Circumscripta.

Dr. Guennell writes as follows to the *Brit. M. J.*, August 20, 1887: I have just had under my care a case of sore-throat very similar to those described by Mr. Alfred Barrett in the *Journal* of July 23d. A boy, aged 6, was brought to me on July 7th by his mother, who said that he was "out of sorts," but he had not complained to her of anything in particular. He was anæmic, and looked ill. On examining his throat, I found the left tonsil slightly enlarged, but not very congested, and on its surface, just as Mr. Barrett describes, a circumscribed ash-colored slough about the size of a shilling, and deeply imbedded. There was an enlarged gland about the size of a pigeon's egg at the angle of the jaw. The temperature, pulse, and urine were normal, and the only symptom complained of was thirst.

I ordered iron and chlorate of potash internally, and the throat to be painted occasionally with Beaufoy's preparation of chloride of soda, and also a gargle of the latter to be used three times a day. I saw the patient daily, and for the first week there was no change whatever in the appearance of the throat, but some increase in the glands. On the tenth day of the disease, the slough showed some signs of separating, becoming detached at the edges; however, it did not come away until the twelfth day, during the act of gargling, leaving a pit in the tonsil about a third of an inch in depth. Since this time the patient has gone on uninterruptedly well, and there are as yet no symptoms of paralysis.

In looking over various medical works on the subject, I have been unable to find any mention of diphtheria assuming this particular form. From the fact that several of the cases referred to by Mr. Barrett have developed symptoms of paralysis, there can be

little doubt that these cases are of a diphtheritic nature.

Simple Ulcer of the Œsophagus With Stricture.

M. Debove had noted in 1883 and 1885 the existence of stricture of the œsophagus in persons unaffected with cancer, syphilis or tumors. He supposed this stricture to be due to cicatrization of simple ulcers of the œsophagus. An autopsy has given him the chance to prove the correctness of his hypothesis. A patient whom Debove had presented in 1885 to the *Société des hôpitaux* died in his service of a perforation of the stomach caused by a simple ulcer. There was also found in the œsophagus, three-quarters of an inch from the cardiac orifice, an annular raised cicatrix, which evidently corresponded to the stricture which Debove had successfully dilated two years before.—*Concours Médical*, August 20th, 1887.

Case of Foreign Body with Calculous Formation in the Female Urethra.

The *Medical Press and Circular*, August 17, 1887, reports the following case from the *Hôpital Bichat*, where the patient was under the care of Dr. Lacorbière: Adela B., aged 18, was stated to have been gradually losing health and strength. Formerly in the best of health, well formed, and of pleasing appearance, she had become pale and depressed in spirits, sombre and taciturn, and was very emaciated. Not finding anything in the viscera to account for this state of things, the investigation was directed to the reproductive organs, but the patient evinced the greatest objection to any examination. Her scruples were overcome, when the parts were seen to be bathed in a large quantity of thick greenish yellow discharge, with a most offensive odor. Metritis, or at any rate, severe vaginitis was suspected, but beyond the vulva, the organs were perfectly healthy. The orifice of the urethra, however, was unusually large and gaping, and a closer examination showed that the extremely offensive discharge came from it. On dilating the urethra still further, a large foreign body of some sort could be detected, and after long and painful manipulation, a pencil case was withdrawn, covered throughout with a yellow concretion composed of triple phosphate. It was three inches long, and an inch and a-half thick, and weighed several ounces. After its removal the patient rapidly regained weight, and improved materially in health. No explanation could be obtained of its introduction.

A Plant which Destroys our Tasting Capacity for Sweet and Bitter.

The *Wien. Med. Blät.* says that lately a drug, which possesses the property of rendering our sense of taste unsusceptible to sweet and bitter, has aroused the interest of the London medical circles, as it is hoped that by its aid our as yet limited knowledge of the physiology of the sense of taste may be extended, and that it may prove a valuable addition to materia medica. The drug, which reached the manager of the King's gardens at Kew, through the Governor of Madras, Sir Montagu, Grant Duff, was examined by Professor Thisleton Dyer, etc., and the statements made above corroborated. David Cooper delivered a lecture on the subject lately, at Ootacamund, from which the following is stated: "The drug is obtained from *Gymnema Sylvestre* (R. Br.), an asclepiadaceous plant, which inhabits the peninsula Deccan, Assam, and the coast of Coromandel; it also occurs on the continent of Africa. It is represented as a strong, woody, climbing plant, with long, thin branches. The leaves are from $1\frac{1}{2}$ to 3 inches long, 1 to 2 inches broad, entire, elliptical to egg shaped, and occasionally cordate at the base, covered with woolly hairs; the upper surface is dark green. The plant is alluded to in the Indian Pharmacopœia. The powdered bark has long been employed by the Hindoos as a remedy for snake-bite. For this purpose the decoction is applied externally. But the most remarkable property was discovered by Captain Edgeworth, who found that after chewing the leaves the tongue lost its capacity of distinguishing the taste of sugar or anything sweet. Powdered sugar had no taste whatever, feeling like so much sand in the mouth. This effect lasted for 24 hours. It is remarkable that the sense of taste for sour, acrid, burning or salt substances is not impaired. When under the effect of this drug, sulphate of quinine tastes like lime. The lecturer found that the peculiar effect did not last 24 hours, but passed off in less than two hours. The chemical analysis showed the drug to contain two resins, of which one is soluble in alcohol; the other, which is present in greater quantity, insoluble. Through suitable treatment, an organic acid was separated, which bears some resemblance to chrysophanic acid. This acid, gymnemic acid, possesses the property of the drug, and constitutes, combined with an undetermined base, about 6 per cent. of the leaves.—*Phar. Record*, Aug. 1st, 1887.

Treatment of Gummatus Infiltrations.

Cardone recommends injections of corrosive sublimate into the bases of the infiltrations. He has treated in this way three patients with tertiary syphilis, with very good results. A girl, thirteen years old, who had a gumma at the root of the tongue, received three injections of corrosive sublimate in three days, when the infiltration shrank and in a few days entirely disappeared. In another patient, a gumma on the point of the nose, for which iodide of potash had been long unsuccessfully given, disappeared after four injections. In a case of multiple gummata, a large gumma disappeared in a short time after six deep-seated injections, while the others, which were not treated in this way, broke down and formed large ulcers.—*La Riforma med.*—*Allgemeine med. Central-Zeitung*, September 3, 1887.

Injectons of Quinine in Gonorrhœa.

Dr. Ledetsch states that he has been able to cure some chronic cases of gonorrhœa in a few days by using the following injection:

R. Quin. bisulph.....	gr. xv
Glycerini.....	fʒvii
Aquæ destil.....	fʒiiss

M.—To be used at first three times a day, then twice a day, and subsequently only once a day.

Except a slight burning, this solution has no unpleasant results.—*Prager med. Wochenschr.*, No. 32, 1887.

Chloride of Zinc in Gonorrhœal Vaginitis.

Fritsch recommends chloride of zinc as a remedy that has given him surprisingly good results. He prescribes chloride of zinc and water in equal parts, and adds of this 100 per cent. chloride of zinc solution five drachms to one and three-fourths pints of water. This injection, at a temperature of about 100° F., is given to the patient when she is lying down, twice daily, even during menstruation. Generally after ten injections the discharge subsides. Of course it returns in cases in which the cervix, endometrium and tubes are affected. Then the cavity of the uterus is cauterized with a strong solution of chloride of zinc and an iodoform tampon applied. Without claiming to have completely cured gonorrhœa, this method gave him such good results that he felt it to be his duty to recommend it to his associates.—*Allgemeine med. Central-Zeitung*, August 6th, 1887.

A Large Nasal Stone.

Dr. Nolte reports to the *Allgemeine med. Central-Zeitung*, August 20, 1887, the following case:

At the beginning of August of this year, a woman forty years old came to him suffering from great fetor of the breath, and saying that she had a sore mouth. An examination disclosed a foreign body projecting into the mouth from the junction of the hard with the soft palate. From its hardness, and from the sound it gave when touched, a stone was suspected. This, from its weight and rough surface had gradually forced its way from the posterior nares through the hard palate. The patient had been aware of a peculiar, indescribable feeling for two years.

A slight incision was sufficient to remove the stone, which, on chemical examination, was found to consist of phosphate of lime, carbonate of lime, ammonia, magnesian phosphate; iron, potash and sodium in traces, and dried nasal mucus.

A Case of Suppurative Pylephlebitis Arising as an Acute Affection from the Mucous Membrane of the Stomach.

S. Laache reports the following case to the *Central. f. Klin. Med.*, No. 47, 1886:

A young student, twenty-four years old, who had previously enjoyed good health, was taken sick after swallowing some ice water, with chills, bilious vomiting, diarrhoea and fever. He had a moderate amount of jaundice, and repeated epistaxis. The liver was enlarged, the region of the gall-bladder tender, the spleen of normal size, and the urine contained bile pigment. Copious vomiting was continuous, finally becoming very black, and consisting of a sour-smelling fluid. The patient succumbed after an illness of about fourteen days.

At the autopsy, a thrombus in a state of softening, was found occupying the portal vein, and in the liver, numerous abscesses of different sizes. The epithelium of the mucous membrane of the stomach was peeled off, especially along the greater curvature. A thrombus completely plugged the gastropiploic vein. In the lower part of the ileum was a spot resembling the altered mucous membrane of the stomach, but no thrombi were found in the neighboring veins.

In the thrombi and in the abscesses of the liver, numerous very small diplococci, and slender, tolerably long bacilli, were discovered. By inoculation of pure cultures of

these bacteria in rabbits, small abscesses were produced.

It must be considered probable, that in the present case an infection had occurred through the abraded mucous membrane of the stomach, and that the loss of substance in the latter had been effected by the ice water.—*Centralblatt f. d. med. Wissensch.*, September 3, 1887.

Aneurism and Atheroma of the Aorta in Childhood.

Sanné, in the course of a paper in *Rev. Mens. des Malad. de L'enf.*, February, 1887, says: That diseases of the large vessels, particularly aneurism, belong to the very rarest occurrences of childhood. But that immunity is not absolute, is proved by several contributions to the subject, of which the author cites four. In the first case a child, otherwise well developed, was still-born in a breech position, and at the autopsy Phœnoménou found an aneurism of the abdominal aorta (*Vid: Arch. f. Gyn.*, 1882). In the second case (*Bull. de la Soc. Méd. des hôp. de Paris*, 1863, p. 499), Roger contributes the history of a boy, ten years old, in which all the clinical symptoms pointed to the presence of an aneurism of the arch of the aorta. The later fate of the patient is not given. The third case is one observed by Sanné himself. He had diagnosed dilatation of the aorta and insufficiency of the semi-lunar valves, in a boy thirteen and-a-half years old. At the autopsy there was found considerable widening of the ascending arch of the aorta, and on the inner surface of the artery, changes indicative of endarteritis deformans; while on the convex side of the descending aorta, at its upper part, was an aneurism the size of a hazel-nut. The inner side of the sac was lined with calcareous plates; the aortic valves were thickened and likewise infiltrated with lime. The fourth case was reported by Moutard-Martin (*Bull. de la Société anatomique*, 1875, p. 775), and illustrates the earliest stage of the formation of aneurism. A boy, two years old, died with symptoms of endo and pericarditis. At the autopsy, besides the recent diseases, there were found superficial, yellowish white elevations upon the inner surface of the intima at the origin of the aorta, as they occur in the earlier stages of endarteritis.

From these reports it is evident that aneurisms of the aorta are found in children at all ages, and even during intra-uterine life. Moreover, neither anatomical nor clinical

differences are to be observed in the phenomena as they occur in infancy and in adult life. The point of origin, also, is the same, and so is the cause, namely, an endarteritis. The presence or absence of syphilis does not seem to have been stated.—*Centralblatt f. d. Med. Wissensch.*, September 3, 1887.

The Methods of Treatment of Prostatitis, with Especial Reference to Hypertrophy of the Prostate.

In this book, which has been recently published at Leipsic, Dr. Leopold Fischer, after a short account of the different forms of prostatitis, gives a thoughtful summary of all the useful methods of treatment. In the acute form, he rejects the treatment by local abstraction of blood recommended by Thompson and Pauli, as in the long run useless; and decides for the local application of cold, in the form of poultices, ice-bags or washings. For the after-treatment, in order to avoid subsequent hypertrophy, he recommends, besides a dietetic regimen, the use of a douche, as especially successful, even in chronic prostatic hypertrophy. For this purpose, the apparatus devised by Von Nussbaum may be used. This consists in a contrivance by means of which a jet or spray of water can be thrown upon the perineum as the patient sits upon a commode. This douche should be continued some time, and used several times a day, the temperature of the water being from 77° – 95° F. With reference to the much-used dilatation of the urethra, the author thinks that, if practiced gently and for a short time, it is of slight benefit, but practiced roughly and for a long time it is decidedly dangerous. If there should be marked retention of urine with catheterismus, the suprapubic puncture of the bladder should be preferred to all other methods, and Nélaton's catheter introduced and allowed to stay in.—*Deutsche Medizinal-Zeitung*, September 5, 1887.

BOOK REVIEWS.

Surgery: its Theory and Practice. By William Johnson Walsham, F.R.C.S., Assistant Surgeon to St. Bartholomew's Hospital, etc. With 236 illustrations. 8vo., pp. x, 655. Philadelphia: P. Blakiston, Son & Co., 1887. Price, \$3.00.

This work opens with two interesting sections on surgical pathology, which are com-

plete enough to include that rare and imperfectly understood condition called "Raynaud's Disease," and which very fairly represent the present state of knowledge in regard to the subject. We regret to observe the simple faith with which the author repeats the common opinions of the laity in regard to hydrophobia—for example, that the discharge of viscid saliva and hallucinations are "characteristic" signs of this disorder, and his recommendation that Pasteur's inoculations for anticipated hydrophobia, and ought not to be neglected. He inclines also to the belief that tetanus is of bacterial origin, and in other respects seems to have accepted views which are not only still unproved, but improbable.

In general, the work of the author is very good. The typography of the book is excellent and the illustrations well adapted to their object, not a few of them being quite old acquaintances.

Handbook of Gynæcological Operations. By Alban H. G. Doran, F.R.C.S., Surgeon to Out-patients, Samaritan Free Hospital for Women and Children, London, etc. With illustrations. 8vo., pp. xii, 485. Philadelphia: P. Blakiston, Son & Co., 1887. Price, \$4.50.

This book is devoted to surgical operations upon the genito-urinary organs of women, and omits consideration of purely therapeutic or obstetrical measures. In the department of which it treats it is a master-piece, being sensible, thorough, clear and admirably written. The illustrations, of which there are very many, are of the highest order of excellence and quite in keeping with the quality of the text. We do not hesitate to recommend it strongly to our readers.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—*B. Westermann & Co.* announce the early publication of Dr. Robert Koch's full report of his journey to Egypt and India five years ago, to investigate the cholera for the German Government. His oldest assistant, Dr. Gafky, has undertaken the preparation of the report. The work will contain many illustrations, among them about thirty plates. The price will be about \$8.80.

—*Lea Brothers & Co.* announce that after the 1st of January the *American Journal of the Medical Sciences* will appear as a monthly instead of as a quarterly.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

NERVOUS PALPITATION CURED BY CLIMBING STAIRS.

Dr. Theodore Clemens, of Frankford-on-the-Main, describes in the *All. Med. Central-Zeitung*, Sept. 10, 1887, an interesting case, in which a well-to-do man, 46 years old, came to him for electrical treatment on account of distress and irregularity in the action of his heart. Clemens, guided by the teachings of Stokes and of Cœrtel, decided to make him do the thing he most dreaded, namely: climb up several flights of stairs. Much as the patient feared the result of this experiment, he made it when accompanied by his physician. The effect was most happy. The patient's pulse, which had intermitted at each tenth or twelfth beat, wavered only twice, and but slightly, in a hundred beats after he had mounted three flights of stairs twice. He now decided to make similar efforts regularly every day, and in three months he was a well man.

This method—systematic exercise for the cure of certain forms of heart disease—is abundantly deserving of consideration. Its effects ought, of course, to be carefully studied, and it cannot be pursued if it produces—as it may—aggravation of the disorder in any particular case. But there are doubtless many cases which are treated in vain with rest, and tonics, and cardiac stimulants, which would be much improved if exercise were substituted for these measures. Such hearts need to be strengthened by work, and are only weakened by being spared from it.

THE COMMUNICABILITY OF TUBERCULOSIS.

In some respects the advocates of the specific properties of the tubercle bacillus seem to be proving too much. If one could credit all that is claimed for it, the wonder would be that the human race has not long since disappeared from the face of the earth. In his recent lecture at the opening of the current term of the Jefferson Medical College, Dr. Da Costa called attention to this point: "When I see," he said, "in popular journals descriptions of the minute organisms in the water we drink, attached to the food we eat; when I hear the ingenious researches commented on that show some of the worst of them, as of the bacillus of tubercle, floating in the air of places of amusement; when in a literary monthly review of great repute I meet with an able article on the 'Creatures we Breathe,' and find that an enthusiastic observer, seated in a railway carriage, notes on the closed window of a compartment containing ten persons, upwards of three thousand organisms falling on the square foot in one minute; I wonder what fright and terror is to be induced by all this, or what will come from its constant contemplation."

To this may now be added the terror of flies. Drs. Spillman and Haushalter have recently reported to the Academy of Science, of Paris (see the last number of the REPORTER, p. 517), that they have been studying the possibility of the communication of phthisis by flies. They have noted the pertinacity with which flies cling to the cups used for

the sputa of consumptives, and have caught and investigated some of them. Such flies, they found, soon died, and in their abdomen and excrement they discovered many tubercle bacilli. After death these flies dry up and fall into dust which may spread the germs of tuberculosis everywhere. More than this, before they die such flies may deposit these germs in food or drink, by defecation, and so disperse the contagion.

This idea is far from pleasant at the best, and it would be horrible if it were not for the fact that there is no reason to believe it is well founded. Observation does not confirm any such frightful theory; and those who advocate it are—as we have remarked above—trying to prove too much. If their suppositions were correct, who would escape consumption? To explain the immunity from tuberculosis of so large a proportion of the human race by the assertion that they do not present a soil suitable for the growth and multiplication of the tubercle bacillus is to beg the question, and to forget the many cases in which inoculation of healthy subjects is said to have taken place in much less likely ways than are suggested by this fly-theory.

For the present we think it not unwise to accept the evidence of clinical experience in this matter, rather than the hypotheses founded on laboratory experiments, and to believe that neither places of amusement, nor railway carriages, nor flies need have special terrors for one of sound mind and fairly sound body.

DISINFECTION.

The occurrence at one time of cholera at the port of New York, of an unusual number of cases of typhoid fever in one district in Philadelphia, and of yellow-fever at Tampa, Florida, attracts attention to the subject of the means of preventing the spreading of these disorders. Among these means none is of greater importance than disinfection. This subject has just been under consideration by the Sixth International Congress for Hygiene and Demography, held in Vienna. At this meeting, Dr. Löffler, of Berlin, made

an elaborate report on the subject of disinfection. He recommended the most scrupulous cleanliness of the patients, their animate and inanimate surroundings, of the sick-rooms and their contents; frequent and thorough renewal of the air of the room in which the sick remain; and the removal and rendering innocuous of dangerous objects. Washing in carbolized water occupies an important part in his recommendations, and steaming of clothing. The discharges of patients with infectious diseases should be received at once in vessels one-quarter full of a five per cent. solution of carbolic acid. Closets should not be used by such patients at all; but, if they are used unavoidably, the seats, as well as the pipes, should be cleaned at once with large quantities of a like solution of carbolic acid. Neither food nor drink should be kept in the sick-room, and no person should share the food used by the patient. Bad odors should be corrected by removing their cause and by ventilation. Attempts to correct them with matter having a more powerful odor can only do harm by concealing them.

Dr. Löffler recommends the most elaborate cleansing and disinfection of furniture of all sorts, including carpets and curtains, as well as all towels and articles of clothing which have been used about a patient with an infectious disease. All cheap things he would have burned, if they cannot be thoroughly disinfected. No patient should ever be transported in a vehicle—by land or water—which is used by the public; nor should he go about except after a most thorough washing with warm water and soap, and in perfectly clean clothing.

The bodies of those who have died of cholera, small-pox, diphtheria, or typhoid fever, he thinks, should be closed up in a coffin as soon as the fact of death is discovered, without washing, and wrapped in a linen cloth soaked in a five per cent. solution of carbolic acid.

These suggestions harmonize with the general opinion of hygienists in regard to the necessity for the most painstaking efforts to prevent the spread of contagious and infec-

tious diseases. Personal experience may lead one or another medical men to doubt the necessity for certain of the details which Löffler thinks important; but in the present state of our knowledge it is best to spare no trouble, and even to do what may not be easy or pleasant in order to prevent the spreading of diseases which sometimes makes such fearful ravages. Whenever they make their appearance the good of the community is at stake, and personal opinions or wishes must give way to what the most careful students of public health think desirable.

It is to be hoped that our country may long be spared from any widespread epidemic; but this seems now to be attainable only by a wise observation of such preventive measures as we have cited above.

NOTES AND COMMENTS.

Report of a Case of Biliary Calculi With Absence of Gall-Bladder.

Dr. Tinsley Brown, M. D., Hamilton, Mo., reports the following case in the transactions of the Medical Association of Missouri, 1887:

I was called on May 19th, 1882, to see Mr. G. G., aged forty-two, who was suffering from an attack of gall-stone impaction. The attack was made manifest by severe pain, chill and persistent vomiting, and followed by extreme jaundice. The pain was relieved by the inhalation of chloroform and hypodermic injections of morphine. The patient was confined to his bed for a week, and did not fully recover for six or eight weeks. There was a history of a previous attack about six years before. His father died at an advanced age from biliary colic and some sort of obstruction of the bowels. His whole family was of a bilious temperament. After the pain was relieved, his after-treatment was by laxatives and alkalies, the principal remedy being phosphate of soda. The patient remained in a fair state of health for three years and a half, when he again began to have attacks of biliary colic. By washing the discharge from the bowels after one of these attacks, I found pieces of biliary calculi. All medical treatment failed to keep off his attacks for any length of time. Over-work, or going past meal-time without eating, would bring on his paroxysms. In January of this year he started to New York

on some business, going to Chicago first with some stock. He was taken sick on the way, and was confined to bed a great portion of his time while away from home, which was about three weeks. At one time he vomited material which had a fecal odor.

In one week after returning home, he was taken violently ill, with severe pain and uncontrollable vomiting. This was followed by a temperature of 103°. I could at no time detect the gall-bladder. The area of hepatic dullness was normal, and the bowels were constipated. He, at all times when sick with this trouble, had had more or less trouble in passing his urine, perhaps from the use of morphine. Morphine and chloroform relieved the pain, but he still vomited.

In fourteen hours he had a violent chill, requiring one or two persons to hold him in bed. After this, there was much fever; pulse 130, and irregular. In twelve hours he was apparently pulseless, and vomiting continually. On one or two occasions the material vomited emitted a fecal odor. In forty-eight hours his pulse had become better, and vomiting less. We then entertained great hope of his recovery, but his favorable symptoms soon failed, and he died on the eighth day of his illness.

Post-mortem fourteen hours after death.—Much emaciation, skin and adipose tissue extremely jaundiced. The liver was found to be of normal size. Only slight signs of any recent peritonitis in the region of the common bile duct. Stomach contained some mucus, but was not inflamed; no stricture of the pylorus, but a slight stricture of the duodenum existed at the entrance of the bile duct; signs of old inflammation around the common bile duct, which was sacculated somewhat like a bubble blown on a glass tube, to the extent of one-half inch, or more. The gall-bladder was entirely absent, there being no trace of it, save the sacculated place in the bile duct. The common bile duct contained four calculi, weighing respectively 22, 23, 25 and 29 grains. There was complete occlusion of the duct at its orifice, caused by impaction of one of the calculi. The gall-bladder probably had been destroyed a number of years before, if it ever had existed, as there were no signs of it.

Surgical Instruction to Railroad Conductors.

As railroads multiply and their equipment is perfected and their service made more methodical, more and more attention is paid to the care of injured persons. All railroads now have regular division surgeons and many have surgeons-in-chief. In cases of

accident between stations considerable time frequently elapses before a surgeon's services can be secured. To prevent serious consequences from the exposure of the patient's wounds, or loss of blood, many railroad companies provide for every train a box containing surgical dressings and simple appliances with printed directions to be followed in case of emergency till the arrival of the surgeon.

In the majority of instances these means will be found, we believe, of but trifling advantage in the absence of persons skilled, to some extent, in meeting such emergencies. To fulfill this requirement also, attempts have been made to furnish instruction to trainmen by means of an annual lecture, so that they might be competent to supply temporary relief to the injured. Such means will be altogether inefficient to render a man who is otherwise without surgical skill or training, capable to check hemorrhage, antiseptically occlude a wound or splint a broken bone.

These are the most important duties which would devolve on the *pro tempore* surgeons, and they *cannot be taught by lectures alone*, especially to an indiscriminate and volunteer audience. Probably the most practicable plan would be to have the necessary (and only the necessary) instruction given to all conductors and to have this course of instruction laid down in a manual, which should be for the double purpose of defining the duties of the conductor, in cases of personal injury, till the arrival of the surgeon, and of refreshing the memory of the former in case of need. The indiscriminate use of apparently harmless appliances have often followed by disaster, especially the application of the field tourniquet and elastic bandage, both of which in the hands of the unskilled are capable of causing irreparable damage. A brief but painstaking course of personal instruction by railroad surgeons to train conductors in emergency practice, teaching them not only how to do good, but what is more important, how to avoid doing harm, would be a valuable addition to railroad service; but to be efficient it must have been the sanction of the management, and become part of the duty both of surgeons and train conductors.—*Pittsburgh Med. Review*, August 30, 1887.

Immediate Relief for Lumbago.

Dr. Burggraave recommends painting the painful parts with the following :

An Error in Diagnosis.

Dr. F. Bradnack tells the following amusing story: It is not often that even a layman commits so curious an error in diagnosis as the one I am about to relate. A young man of twenty consulted me, complaining that he was suffering from "the itch." Upon questioning him as to how he contracted it he replied that some weeks before he had slept in the same bed with a man who had had the itch for some time. After this history I physically examined him—not only his hands, but his entire body. At the conclusion of my examination, he inquired: "Well, doctor, I suppose this disease *could* be taken by sleeping with a man, could it not?" Whereupon I replied: "The disease which you have could, in my opinion, only be taken by sleeping with a woman!" At this reply he at first appeared greatly astonished, but after some hesitation confessed that about two months before he had, on one unlucky night, made his first entrance into a house of ill-fame.

What I found in examining him was a well-pronounced Hunterian chancre, with marked induration of the inguinal glands on both sides, together with a squamous syphilide not only on the hands, but *nearly all over* the body. This (due to the fact that it at times itched slightly) he had concluded was "the itch." Until very recently he had not noticed either the chancre or the indurated inguinal glands.

He had consulted a quack, who, after charging him nothing for treatment, but \$5.00 apiece for two bottles of "medicine" (?), frankly confessed that "it was hard to say what was the matter with him."

This patient is now upon a vigorous anti-syphilitic treatment, and may, meantime, for a year or two, console himself with the poetic and philosophic reflection that "to err is human"—not only in the field of morals, but likewise in the even more difficult field of medical diagnosis.—*The Med. Press (N. Y.)*, September, 1887.

Distillery Swill as a Food for Milch-Cows.

Mr. Charles Cabanne writes as follows in *Science* of August 5, 1887:

Some eighteen years ago I owned a dairy, and run on one thousand acres of land eight hundred cows. I had one stable that held 672 cows; it was kept clean, and was well ventilated. For eighteen months I fed distillery-swill. From my experience in feeding swill to milch-cows, I should say that it produces tuberculosis. In addition to swill,

I fed grass and hay, and during the summer months "soiled." At the expiration of eighteen months I stopped feeding swill, and the number of cows that had to be disposed of because they had consumption was reduced to so few, that I do not now remember that there were any. It is my opinion that if cows are closely confined and fed on swill and hay exclusively, tuberculosis will develop in nine cows out of every ten inside of a year. The nutritive quality of swill food depends upon the amount of water put upon the grains after fermentation. I have never had any practical experience in feeding sweet distillery swill; but if fed in moderate quantities, not too hot and sweet, and with hay and other dry and very nutritious food, I can see no reason why it should be harmful. Parties who produce swill-milk for sale in large cities find swill to be the cheapest food for the production of milk, and consequently use it to excess. I have never seen swill fed sweet in more than one city dairy, and I have been in fifty.

The Usefulness of Terebene in Diseases of the Lungs.

Dr. D. M. Cammann, of New York, has been using terebene largely in diseases of the lungs. He sums up the results he has obtained from its use, as follows:

An analysis of the histories of eighteen cases shows that eight were emphysema, six bronchitis, three phthisis, and one asthma and bronchitis. Two cases of bronchitis, one of which had lasted for a few days, and the other for a month, were cured. Three cases of chronic bronchitis showed great improvement. One case showed no improvement after taking ten drops of terebene every four hours for five days. In this case the treatment was subsequently changed several times without any improvement occurring in the patient's condition. Seven of the cases of emphysema improved, and most of them to a marked degree. One case was unimproved after taking the medicine for two months. The three cases of phthisis and the case of asthma all improved. The time that the cases were treated varied from a few days to five months. The average length of treatment was fifty-five days. The terebene was given either dropped on sugar or in a mucilaginous mixture, in doses of from ten to fifteen minims, three or four times daily, and occasionally more frequently. In nearly every case the terebene was given without any other drug. Of these eighteen cases only two, or one in nine, were

unimproved. In the other cases the dyspnoea was diminished, and usually to a marked degree. In fact, dyspnoea was the symptom upon which terebene seemed to have the most uniform and favorable results. The expectoration was thinner and lessened in quantity. In eight out of sixteen cases the patients said that the urine was increased; in the other eight cases they had noticed no change. In two cases vomiting occurred, but it was after eating or coughing, and the patients themselves did not attribute it to the medicine. In two cases hæmoptysis ceased a short time after taking the terebene. I regret that it has been possible for me to use it in only two cases of hemorrhage, as the result was so favorable as to warrant its further trial.

Terebene in some of its effects resembles turpentine, but is less irritating. In one case a patient took by mistake a teaspoonful every four hours for a week without any unfavorable result (Murrell). In none of my cases were the bowels affected. In those in which the urine was increased, no signs of extreme irritation followed, even when the drug was used for several months.

In addition to the cases already mentioned I have used terebene in forty or more cases in which histories have not been kept, but in which the results were equally favorable.

The cases reported in this paper are not, perhaps, a sufficient number from which to draw general conclusions, but taken in connection with those already reported it may be said that we have in terebene a valuable drug. It is useful in acute cases, and in chronic cases of emphysema it seems especially beneficial in relieving the dyspnoea.—*Medical Record*, Oct. 8, 1887.

Removal of Needles from the Heart.

The *Centra. f. Chirurgie* contains the following account of a case of Stetzner's, which was communicated to the German Surgical Society:

A student, after a spree, sought to commit suicide by driving a sewing needle into his heart. Twelve hours after the introduction of the needle the first serious symptoms made their appearance. He then had pain in the cardiac region, difficulty in breathing, and a loud pericardial murmur at the apex. After thirty-six hours the symptoms became so very serious that an operation for the removal of the foreign body was determined upon. No trace of the needle being found either under the skin or in the intercostal space, a piece of the fifth rib was resected, thus

opening up the left pleural cavity; then the pericardium was opened up, and about a teaspoonful of cloudy pericardial fluid ran out, and now the needle could be felt lying diagonally in the right ventricle. They succeeded in driving its head out through the anterior wall of the heart, and then fixing it in this position with the finger-nail. The irregular and violent beating of the heart made it very difficult to catch the foreign body with the forceps, and, in attempting it, it again slipped into the ventricle, but this time assuming a vertical instead of a diagonal position, rendering it impossible to make any further attempt at its removal; and besides this, an iodoform tampon, used to block up the hole into the pleural cavity, was drawn into the cavity by a very deep inspiratory effort. The tampon could not be found again. The wound was thoroughly tamponed, and the patient recovered in four weeks, although in the meantime he had suffered from a severe pneumo-thorax, with copious exudation. At present the patient enjoys good health, and feels no effects from his escapade. There is neither heart murmur nor abnormal pulse, nor any trace whatever of the pleural exudation. Where the needle now is, is, of course, mere matter of speculation; it may be in the heart, or it may have gone on into the mediastinum.

Dr. Iver Hardt has collected together, out of medical literature, twenty-two cases of needle in the heart, of which nineteen were found accidentally on making autopsies. In three cases the needles had been driven into the heart accidentally, and penetrated such a short distance that they were easily extracted.

No case similar to the present, in which the heart has been laid bare by splitting the pericardium, is mentioned in medical literature.

In the discussion upon the paper, Hahn, of Berlin, showed the half of a knitting needle which V. Bergmann had removed from the heart of a girl eleven years of age. It had been driven into her breast by a blow from a slipper. The patient suffered immediately from asphyxia, and was removed to the hospital. Under the left third rib, between the parasternal and mammillary lines, a black point could be seen, which was felt to be the end of the needle. There was a blowing, systolic murmur at the apex. As the needle was slowly withdrawn, it was seen to have a distinctly pendulum movement. Immediately after the extraction, the previously very rapid pulse sank to ninety per minute. The needle was withdrawn

very slowly, in order to give time for a clot to form in the punctured wound, and thus avoid hemorrhage into the pericardial sack, which, in some cases of punctured wound of the heart, has been the cause of death. Von Bergmann said that he thought there could be no doubt in this case of the puncture of the heart muscle by the needle, because the murmur changed in character while the needle was being withdrawn, and, when completely removed, the murmur ceased entirely. —*Pacific Med. & Surg. Journal*, September, 1887.

The Toxic Effects of Iodoform, Cutaneous and Systemic.

Dr. R. W. Taylor, Surgeon to the Charity Hospital, New York city, read a paper on this subject before the American Dermatological Association, at its eleventh annual meeting. The following is a summary of his conclusions:

A. Its use as indicated: 1. On fresh wounds.

2. On diseased surfaces—gangrenous, chancreoid, phagedenic, syphilitic, tuberculous—and on those slow to take on healthy granulation.

3. On the surface of necrosed bone.

B. Its use is contra-indicated: 1. On freshly cut bone.

2. On granulating surfaces.

3. In cases in which it is known or is found to produce toxic effects.

C. Modes of use: 1. It should be dusted on the surface lightly and sparingly.

2. In wound-cavities or in the natural cavities as small a quantity as possible should be employed; in the former it is preferable to use it in the form of gauze.

3. It should never be rubbed in with the finger.

4. Its application should be renewed as infrequently as possible.

5. Such aids to absorption as tightly fitting bandages and impermeable dressings should not be used.

6. Its use should be discontinued as soon as healthy granulations appear.

7. It should not be used coincidentally with any other antiseptics, carbolic acid especially (Mosetig-Moorhof).

8. It should be used with great caution in the young and the old; in anæmic and neurotic persons, and those suffering from weak heart or Bright's disease; also in very fat and flabby subjects.

9. Should toxic symptoms appear, the iodoform dressing must be promptly and thoroughly removed.

D. The occurrence of anomalous forms of persistent or recurrent eczema in persons who handle or in any way come in contact with the drug, or who use it as an ointment or in suppositories in the vagina or rectum, should cause the physician to suspect the agent as the possible cause.

E. It is most important that the practitioner should exercise a watchful care over all patients for whom he prescribes this agent, and should he observe morbid symptoms, however mild, pointing to the brain, heart, or lungs, or a tendency to loss of appetite or emaciation, he should cause the discontinuance of its use at once.

F. The treatment of the skin manifestations is similar in all respects to that of the simple eruptions of the same varieties. Systemic poisoning should be treated symptomatically, since we have no specific.—*N. Y. Med. Journal*, Oct. 1, 1887.

Apomorphia in Respiratory Diseases.

Dr. Reynold W. Wilcox, Instructor in Clinical Medicine at the New York Post-Graduate Medical School, Physician to the Demilt Dispensary, has the following communication in the *St. Louis Med. and Surgical Journal*, October, 1887:

In 1884, I began to use apomorphia in diseases of the respiratory organs. As my clinic at the Demilt Dispensary is a general medical one of nearly two thousand new patients each year, I have had abundant opportunity to watch the action of the drug by itself and in contrast with that of similar drugs.

Physiological experiments show that apomorphia produces no depression; if injected into the veins or given hypodermically it produces vomiting as freely after as before section of the pneumogastric; it increases the secretion from the respiratory mucous membrane, producing a thin watery mucus; it diminishes somewhat the vascularity of the bronchial mucous membrane; it stimulates the respiratory center, thus increasing the number of respirations. When old solutions of a markedly green color, or large quantities are given, we get great prostration, as shown by rise of pulse and fall of temperature, depression of the respiratory center, causing slow and shallow respiration. In Carville's case three-tenths of a grain caused collapse in an adult. Therapeutically, I have used apomorphia chiefly in acute bronchitis. In those cases with considerable frontal headache, hot, dry skin, sore throat, marked prostration, rapid pulse, high temperature,

stuffy feeling in chest and soreness in epigastrium, dry teasing cough; when physical examination shows harsh respiration, sonorous and sibilant râles with few coarse and fine mucous râles, are its effects most marked. Here, if one thirty-second to a forty-eighth of a grain be given every two or three hours (for the dose must be frequent, since the effect does not last a long time) one finds the headache relieved, the sore throat disappear, pulse and temperature fall, the cough markedly diminish in frequency and a copious watery expectoration, easily raised, coughed up; the respiration becomes softer, the dry râles disappear and many moist râles are heard. The first daily dose of the apomorphia mixture is taken upon awakening in the morning; resting quietly in bed for a few minutes, a glass of warm milk is taken; in a short time a full breath is followed by a series of coughs by which the night's accumulation of mucus is dislodged and expectorated. Generally there is very little coughing during the day.

The prescription, which may be varied according to each case, is:

R Apomorphinae.....gr. ss ad j
Potassii bromidi.....ʒss
Tincturæ sanguinariae.....ʒj
Syrupi tolutani q. s. ad.....fʒiv

M. et ft. sol.

S.—Teaspoonful every two or three hours in a wineglass of water.

The sanguinaria is added for the benefit of the apothecary, showing him that it is a cough mixture; otherwise he would alarm the patient by telling him that it was an emetic,—a circumstance that has happened more than once.

This prescription, modified according to circumstances, can be used in pneumonia, phthisis, chronic bronchitis and spasmodic laryngitis. It is said that this drug is also useful as a spray in relieving the dry throat of phthisis. Failures will occur in the use of apomorphia, as with any other drug, but I have found it to be due to the use of old specimens or of those solutions which have become decomposed and show quite green.

—Dr. E. D. Mapother reports in the *Medical Press and Circular*, September 28, 1887, a case of elephantiasis of the leg, in a woman eighty years old, which he thinks was due to the fact that she has been obliged, for the past seven years, to occupy the sitting posture, on account of rheumatic stiffening of the hip and knee joints.

CORRESPONDENCE.

Some Results of a Long Experience.

EDS. MED. AND SURG. REPORTER :

Sirs :—In compliance with your request for the chatty communications of physicians, I send you a few points drawn from my experience, which may be useful to some of your readers:

Cure for Rattlesnake Bite.—The Hon. George Vandyke, Mayor of the city of New York, during the late war told me that wet pulverized indigo was a sure and certain cure for the bite of this reptile. I mentioned this to a lady about to start to Florida in February last, who had occasion to use it. Their colored man was bitten above the ankle. He tied a bandage tightly above the ankle, and kept on with his work. When he returned in the afternoon the foot and leg, to the bandage, were swollen dreadfully. Indigo was applied as a poultice, and the man recovered without other treatment for twenty-four hours.

Venesection in Pneumonia.—Long and continued sickness prevented my supporting Dr. Corson at the time of his advocacy of blood-letting in the treatment of acute pneumonia with my experience, confirming the value of that practice. I do not recollect an instance of failure in a large practice in pneumonia, pleurisy or peritonitis, when venesection was employed early—there being early convalescence in all cases. I have no doubt that some congested brains, which were noticed in their premonitory symptoms, would have been relieved and life comfortably prolonged had venesection been resorted to at that early stage, or had a few teaspoonful doses of chloroform been given.

Ringworm disappears rapidly with inunction, night and morning, of an ointment of tobacco, 20 grains to the ounce.

Tetanus I think can be readily cured with strychnine, given every three hours until the dose which produces a little twitching in the arms is exhibited, then to be kept up every six hours. I was interested with a friend in eight successive cases which I published, in his name, as he suggested the remedy. The late Dr. Valentine Mott, after seeing with me a case which ended in death, said: That if ever he was called again to a case of tetanus he would use strychnine, on the principle that its general effect on all of the muscles would control the partial effect on the masseter muscles, as it did this in every case.

The history of one of my cases was as follows: My colored washer-woman, 50 years

old, had opisthotonos and tonic contraction of the diaphragm. I bled her till her jaw dropped—a large wash-basin full—when I thought her dead. But blood was running, and that satisfied me. In a minute the jaw fell. I bandaged the arm and gave tartar emetic in solution, beginning with $\frac{1}{8}$ grain and increasing $\frac{1}{8}$ every two hours until she took four grains at one dose without nausea. She recovered and lived twenty years longer.

The eight cases referred to above were published in the *N. Y. Journal of Medicine*, November and January, 1846 and 1847. The maximum dose of strychnine I used was $\frac{1}{10}$ grain in solution every two hours, until involuntary twitching of the muscles of the extremities took place, when the masseters would relax.

I would not have reported this in your journal, but that I see no regular treatment adopted and repeated deaths reported, and never the use of this remedy.

Yours truly,

EDW. VANDERPOEL.

228 E. 68th Street, New York.

Treatment of Epistaxis.

EDS. MED. AND SURG. REPORTER :

Sirs :—After some trying experiences with troublesome cases of nose-bleed, I took a hint from the practice of a veterinary surgeon which has proved more satisfactory at my hands than plugging the anterior and posterior nares. As he treated a horse, so I treated my patient.

I took a lump of cotton, tied a thread around it, and passed it with a probe back into the nostril, holding the thread in my hand. I pushed it up so far beyond the bleeding point that the blood ran out of the front of nose, and then drew it down with the string until it covered the bleeding spot. Then the bleeding was controlled. I have used this in several cases, and it has met my needs. I give it for what it is worth, and in the hope that it may help some physician when in doubt what to do.

Yours truly, H. N. BURR.

Williamson, N. Y.

Wholesome Influence of Rocky Mountain Air.

EDS. MED. AND SURG. REPORTER :

Sirs :—Seeing the selected article, "The Rocky Mountains for Recreation," in your number for September 3d, I thought my experience in the Rockies might prove of passing interest to those of the profession

suffering from nervous prostration. I had, in 1883, an attack of chills, which in spite of antimalarial treatment, became so chronic as to last four months. When I got well of chills, I kept taking cold every time I was exposed, which, in turn, developed a chronic bronchitis. I consulted my friends near me, and getting no relief, I went to New Orleans and consulted Professor Elliot, who pronounced my trouble consumption. The cough became eventually somewhat asthmatic, and I decided to try the mountains. I went first to El Paso, Texas, and then to Socorro, New Mexico. From Socorro I went to Magdalena, New Mexico, and from Magdalena

I went west in a wagon for one hundred and thirty miles. At Magdalena, I weighed one hundred and twenty-six pounds. I spent about six weeks in the mountains, or drifting from one chain to another, hunting. I slept well, and although I had an occasional spell of asthmatic coughing, I constantly improved. My appetite, which was not good when I reached the mountains, and had been variable a long while before that, began improving after a week or so, to such an extent that I could eat anything any other man could eat. I never ate so ravenously before, and could eat at one sitting what would have made two or three full meals for me at home; and strange as it may appear, I never felt as if I had eaten too much, but would feel wonderfully good after each meal. When I returned to Magdalena I weighed one hundred and forty-six pounds, and felt better than I ever felt before. My mountain experience in becoming accustomed to the rarefied air—in climbing after a time, what was at first the most inaccessible hills—in rising at break of day and shouldering my rifle and walking miles, trudging through snow, in search of deer, without suffering in any way except for something to eat, is beyond my powers of description.

Suffice it to say my cough kept all the while improving while there, and the improvement has so far been so permanent that I have been to all intents and purposes well man ever since my return.

Yours truly, J. E. STINSON, M.D.
Montague, Texas, Sept. 12, 1887.

Persistent Priapism.

EDS. MED. AND SURG. REPORTER:

Sirs:—I wish to write about a case, and like H. C. G., I am entirely willing to leave the disposal of my communication entirely with you. My case may not be strange to others, but in an experience of thirty-six years I have not seen anything of the kind.

I had a patient, 31 years old, die a few days ago from enlargement of the spleen. It was enormously hypertrophied, resting upon the pelvis and filling and distending almost the whole abdomen. The patient continued to go about town to within ten hours of his death, which was due to coma. The singular circumstance connected with the case was persistent and painful priapism for the last week of his life. After death, and up to the time of his burial, there was no relaxation of this condition. The corpus spongiosum and glans was seemingly filled by a solid coagulum. The patient's disease commenced a year ago, and painful erections often troubled him for a few hours at a time, but did become continuous until the time spoken.

Yours truly, A. ADY, M.D.
Muscatine, Iowa, Oct. 7, 1887.

Fluid Extract of Ergot for Incontinence of Urine in Children.

EDS. MED. AND SURG. REPORTER:

Sirs:—I have been using for many years the fluid extract of ergot in the treatment of incontinence of urine in infants and children; and I almost regard it as a specific for the disease. I prefer to give it simply, and not to treat separately any condition of the patients that may require therapeutical aid to correct those states of physical debility which either predispose to incontinence of urine or aggravate its presence. I give to an infant from one to three years old, 5 to 10 drops; and to a patient from three to ten years, 10 to 20 drops every three hours. Few children object to its taste, and it should be continued uninterruptedly for two or three weeks, and resumed if the disease should return, in which case the doses ought to be gradually increased.

Yours truly,
J. B. JOHNSON, M.D.
Washington, D. C.

Pilocarpus in Dropsy.

EDS. MED. AND SURG. REPORTER:

Sirs:—A very obstinate case of general dropsy of several months' standing, which had resisted the famous apocynum cannabinum alone, and other reputed remedies, yielded readily to the following simple treatment:

R. Fld. ext. of pilocarpus pennatifolius. .f3j
Fld. ext. of apocynum cannabinum. .f3iij
Elixir of ginger (or simple elixir) q.s. ad. f3iij

M.—S. One teaspoonful in water three or four times a day.

May I suggest to your readers to try it, and to report the results in the columns of the REPORTER?

B. FRANK HUMPHREYS, M.D.
Hawkins, Tex., Sept. 22, 1887.

NEWS AND MISCELLANY.

Sanitary Reform in Dress.

After speaking of the failure in the past of preaching and sumptuary laws to obtain reform in dress, the *British Medical Journal*, September 17, 1887, proceeds to account for the failure of modern sanitary attacks by saying:

One of the chief factors in this entire failure is the vanity and sycophancy of civilized beings, for which dress reformers make no sufficient allowance. The most frequent cause of the invention of ugly and insanitary costumes has been the attempts made to conceal blemishes or deformities existing in persons of exalted rank, and the new fashions have spread because they were at once imitated by courtiers who thus tacitly flattered the original wearers of them. It was to hide the short stature of Louis XIV that high heels and towering perruques were introduced. The Virgin Queen patronized immense ruffs because her neck was not handsome. Short hair became fashionable in France when an accident to the King's head during a snow-ball fight necessitated the removal of his flowing locks. Full-bottomed wigs were invented by a French barber named Duvillier to conceal the fact that one shoulder of the Dauphin was higher than the other. Charles VII of France wore long coats to hide his ill-made legs. Henry Plantagenet, Duke of Anjou, had his shoes made with long points to screen from observation an excrescence on one foot. Crinoline was introduced by the Empress Eugénie to render her appearance when *enceinte* less noticeable.

Another reason of this failure to reform dress is a want of recognition of some laws which seem to govern both the growth of fashion and the taste of women. Fashions are almost always the result of a definite growth and natural development, and are scarcely ever the outcome of sudden inspirations of tailors or dressmakers. Those garments we attack for inelegance or uselessness can show a historical reason for every apparently meaningless peculiarity, or can give a story of forgotten use for ornaments which are really atrophied survivals from vanished needs.

Every part of the despised dress coat, for example, has a reason for its peculiarity of shape. The apparently foolish nick or slit at the junction of the collar and facings on each side dates from the time when men rode a great deal, and the coat collar must be frequently turned up and the chest buttoned

closely over to meet the severity of sudden storms. A division was made on each side of the collar to permit this to be done, and the present useless slit is the survival of this very needful predecessor.

Not even the buttons which adorn the small of one's back are mere vain ornament. In about the year 1700 it began to be the custom to gather in at the waist the sack-like coat of the period. This was done by two buttons sewn on over the hips, which were attached to loops set on at the edge of the coat. Then, as waists became a permanent fashion, the loops were disused, and the buttons, instead of being discarded, were simply moved a little further back; here they attained to a new usefulness in supporting the sword-belt. Now that sword-belts are no longer worn, these two buttons seem merely a meaningless excrescence.

The very shape of the dress-coat, which has been so much and so often ridiculed, is not an arbitrary fashion, but a natural development. Starting from the ample square-skirted coat of the close of the seventeenth century, itself a development, we next find the same coat with the corners of the skirt buttoned together for convenience of riding; then the same garment with the lap corners cut off instead of buttoned up—the swallow tail of the early years of the present century; finally by a very slight further degeneration the modern dress-coat was produced. Such is a specimen of the history of the gradual evolution of most articles of clothing, an evolution which is one explanation of the inability of sanitary reformers to produce violent evolutions in dress.

Another cause of their failure is that they take a standpoint of simple utility, and ignore the instinctive and inherited desire of the one sex to attract the other by a becoming costume. It is indeed a moot point whether the original adoption of clothing by barbaric nations was not the result merely of the desire of both sexes to attract. "The pangs of hunger and revenge once satisfied," said Carlyle, "the next care of the aboriginal savages was not comfort, but decoration. Warmth he found in the toils of the chase or amid dried leaves in his hollow shed or natural grotto; but for decoration he must have clothes." The same story is told by the discovered remains of palæolithic man. Still in this case may be found the ruddle or rouge with which his wife painted her naked body, and the necklaces, made from the teeth of fierce beasts, wherewith she adorned her hairy neck. Except such simple ornaments as these, clothing was unknown to the early

cave-dweller. Naked as his mother bore him, he chased the gigantic animals of those undegenerate days through the trackless forest, or disputed with them the possession of those caves which were the alternate lair of man and beast. You may still see this early savage in some of the excellent bone-pictures he has left, semi-upright, covered with hair, innocent of clothing, creeping up with noiseless motion to attack with his stone-tipped spear the bison, the wild horse, or the elephant.

In latter days the daughters of a nomadic race sought to render themselves attractive by adopting the trappings of the camels which were their care. As they led their charges to the water by their nose rings, the little bells the camels wore made a melodious jingle in the stillness of the desert. And in forgotten imitation of these ancient servants the stately daughters of Jerusalem came tinkling down the road, with their silver ankle-bells—the maidens of Hindostan yet wear from their nostrils a glorified and jewelled nose-ring—the sons of the East use a sandal in which the attentive observer can still trace the tablet of undressed hide used by the camel-driver for the feet of his valuable beast.

In every age this use of dress as an ornament to attract the other sex has rendered the censure of reformers on its extravagances unavailing. When, for instance, a mania for classicism afflicted the patriots of the French Revolution, the ladies of France adopted the dresses of Greece and Rome, or what they imagined to be such, with fatal eagerness, and with undraped bodies and sandalled feet braved the severity of a Parisian winter. Their light attire exposed them to diseases of the chest; nay, to death itself, but they heeded not. The gold rings shining on their feet could not protect them from the cold of winter, yet they remained faithful to gauze-clad nudity.¹ It was vain to remonstrate with them on their insufficient clothing; with French readiness they would reply with an epigram—

Le diamant seul doit parer
Des attraita que blesse la laine.

In the same way no arguments of its utility or sanity are likely to induce an elderly lady to adopt the curtailed garments recommended by Dr. Jessop, if the result should be to render her an object of ridicule to man when compared with a sister dressed in the trailing garments of modern fashion.

Much may be done, much has been accom-

plished in the direction of sanitary clothing, but it has been by gradual and judicious reform of material, and unseen alteration of undergarments, at the suggestion of medical men, not by sudden and violent changes of fashion and interference with prejudice. Many ladies now actually wear the woven woolen vests and the flannel knickerbocker drawers recommended by Dr. Jessop. Suspenders attached to the stays replace the injurious garter, and clothed necks and shoulders have replaced, at least in the day-time, the low-necked dresses of our grandmothers.

Much remains to be done in this matter, but it must be attempted with a complete appreciation of the difficulties of the position, and with a competent knowledge of feminine laws of thought. Flowing garments, for instance, will in all probability never be forsaken, because of the superior dignity they confer on the female figure. Indeed, in our opinion, the best hope of discarding the hateful stays rests in a gradual return to the beautiful costume of Greece, for it is almost certain that while waists are accentuated, stays will be worn, but the change must take place in the natural direction of gradual development directed by competent and judicious leaders of fashion, not in that of violent and inconsiderate revolutions. Until we are sufficiently educated to accept the wise aphorism of Edward I. as our guide, a complete reform of dress is very hopeless. It was that great king who said: "It is impossible to add to or diminish real worth by outward apparel; the only magnificence we must seek is the magnificence of noble and heroic deeds."

The Manufacture of Cachets and Wafers.

The recent death of Limousin, the inventor of the wafer capsules (cachets, capsulæ amylacææ) suggests the idea of again drawing attention to the utility of this form of medication.

In recent times, the development of the wafer-capsule industry, if it may be so called, has been especially promoted by Mr. Adolph Vomacka, of Prague.

To a certain extent, the choice of this form of medication depends somewhat upon the rate with which its existence or availability is kept before the memory of the prescriber. It only needs a slight impetus, from time to time, to cause a preference in favor of the wafer-capsule over some of the forms of medication, though it is by no means intended to assert that this is in all cases the best form. We believe, however, that it is, for instance,

¹ A fashion they carried so far as to discard chemises for one whole week.

preferable to gelatin capsules in the case of quinine.

Formerly, the wafer-capsules were pressed from the large square wafers (for which Nuremberg has long been celebrated); at the present time, however, they are baked specially. The cost of fitting up a factory is very small, and the arrangements required are simple, requiring but little room and only cheap labor. The most expensive item of the whole are the forms. These are made of two hinged pieces, the material being either steel or brass. One of the plates contains the concave, the other the convex pattern of the wafers.

These forms rest upon one or more specially constructed ovens heated either by gas or wood-charcoal. As soon as the opened forms, resting on the hot oven, have acquired the proper temperature, which is easily recognized by allowing a drop of water to fall upon them, a certain quantity of a mass prepared from wheat-starch is spread upon one of the plates and the other plate gradually folded over it. The latter, through its own weight, expands the mass so that it forms a perfectly uniform layer. The excess of the mass, which is squeezed out at the side, is simply scratched off. The forms are then opened, and the completely baked sheet taken out. This sheet contains as many half wafer capsules as there are patterns. When freshly taken from the form, these sheets are very brittle; but, after being laid aside a few days, they absorb enough moisture from the air to permit being cut or trimmed. The next operation then is the cutting or punching out of the round wafers. For this purpose there are used either simple punches, or punching machines worked by treadles, by means of which each separate wafer is cut out. These are then counted and put up in packages. A well trained girl is able to bake, in one day, 20,000 such wafers, and it requires the service of only two girls to punch these.

The mass of which the wafers are composed consists of the purest wheat-starch, mixed with water. The best fuel is either gas or wood-charcoal. There being only a few requisites, it will be easy to calculate the cost of a day's turn out.

The whole art and mystery of the manufacture centres in the forms, which must be absolutely true and perfect. If the forms are not exactly true, the wafers will be uneven. The least defect of the forms will be prominently visible upon the product.

The preparation of flat wafers, such as are used for making sealing wafers, sacramental wafers, wafer bottoms for ginger-cake, etc.,

is much more simple than that of the medicinal wafers. The former are baked in similar metallic forms, which are, however, entirely smooth inside. The thickness of the wafers depends, of course, upon the distance intervening between the plates when they are closed.—*American Druggist*, August, 1887.

Clever Detection of a Criminal by a Doctor.

A rather novel point in forensic medicine has arisen in connection with the murder at the Rue Montaigne, Paris, the victims of which were a celebrated *démimondaine* who, along with her maid and maid-servant, was found murdered in their apartments under circumstances of great cruelty. Their throats had been cut after a severe struggle, and their bedding and the walls of the apartments in their vicinity were copiously bespattered with blood. The unfortunate chief victim was the possessor of jewellery and other valuables to the extent of some thousand pounds, presumably the motive of the murder. These, however, were in an iron safe, and as the murderer, who was evidently single handed, could neither open this nor carry it away, he had to leave without the wages of his crime. The key was subsequently found concealed in a wardrobe. A man named Pranzini, a follower of the victims, was arrested upon suspicion, but the closest examination of his clothes, both those which he had worn on the evening of the crime and those found at his residence, showed no trace of blood. This was relied upon as a strong point in the defence, but Dr. Brouardel, the *Médecin-légiste* engaged in the matter, recalled the fact that in the next apartment was found a toilet-stand upon which was a large basin-full of ensanguined water, as if some person stained with blood had washed therein. As none of the three victims had presented the appearance of having done this, Dr. Brouardel conceived the idea that the murderer had, on entering the apartments, undressed himself, had committed the crime in a state of nudity, had then carefully washed himself of its traces, and had finally, all being completed, resumed his clothes, of course free from all sanguineous stains. Dr. Brouardel now demanded from the *juge d'instruction* an authorization to examine Pranzini totally undressed, and on this being accomplished found a long tearing scratch (*estafilade*) extending down the front of his right thigh. Interrogated upon this, the prisoner said that he had been attacked by a severe itching in the part and had torn himself in relieving it. Being invited to

repeat the gesture he did so, scratching himself from the knee towards the body, when the medical expert showed that the tear had been produced by nails, or at all events some sharp body, acting from above downwards in the direction of the knee, as was shown by the pointed fragment of epidermis projecting upwards from the lower end of the wound. The expert's hypothesis is that when the assailant approached one of his victims, with the weapon in his right hand and with his right side next her, she inflicted the injury with her nails. Questions of blood-stains on clothing have frequently formed important evidence in murder trials; but the present is probably the first instance of an ingenious plan having been adopted to escape clothing stains, and of its being defeated by an accident developed by the acuteness of the medical expert. Pranzini was convicted, without extenuating circumstances, and was sentenced to death by the guillotine.—*Dublin Journal of Med. Science*, August, 1887.

University of Pennsylvania.

At the monthly meeting of the Board of Trustees of the University of Pennsylvania, on Monday, October 3d, Dr. Samuel G. Dixon was elected Professor of Hygiene in the Auxiliary Faculty of Medicine, in place of the late Dr. N. Archer Randolph; and Dr. A. H. P. Leuf was elected Assistant Director of Physical Education.

Medical Instinct.

Animals get rid of their parasites by using dust, mud, clay, etc. Those suffering from fever restrict their diet, keep quiet, seek dark, airy places, drink water, and sometimes plunge into it. When a dog has lost his appetite, it eats that species of grass known as dog's grass, which acts as an emetic and purgative. Cats also eat grass. Sheep and cows, when ill, also seek out certain herbs. An animal suffering from chronic rheumatism always keeps, as far as possible, in the sun. The warrior ants have regularly-organized ambulances. Latrelle cut the antennæ of an ant, and other ants came and covered the wounded part with a transparent fluid secreted in their little mouths.

If a chimpanzee is wounded, it stops the bleeding by placing its hand on the wound, and dressing it with leaves or grass. When an animal has a wounded leg or arm hanging on, it completes the amputation with its teeth. A dog, on being stung on the muzzle by a viper, was observed to plunge its head repeatedly for several days in running water. The animal eventually recovered.

A sporting dog was run over by a carriage. During three weeks in winter it remained lying in a brook, where its food was taken to it. The animal recovered. A terrier hurt its right eye. It remained under a counter, avoided heat and light, although it habitually kept close to the fire. It adopted a general treatment, rest and abstinence from food. The local treatment consisted in licking the upper surface of the paw, which it applied to the wounded eye; again licking the paw when it became dry.

Animals suffering from rheumatic fever treat themselves by the continued application of cold water, which M. Delauney considers to be more certain than any of the other methods. In view of these interesting facts we are, he thinks, forced to admit that hygiene and therapeutics, as produced by animals, may, in the interest of psychology, be studied with advantage. Many physicians have been observers of animals, their diseases, and the methods adopted by them in their instinct to cure themselves, and have appropriated the knowledge so brought under their observation in their practice.—*Am. Druggist*, Aug., 1887.

Official Analysis of Beer.

The Commissioner of Internal Revenue said recently that he intends to make analytical tests of various kinds of beer sold throughout the country. The chemist of the Bureau is now getting ready to make these tests. The breweries will not be called upon for samples, but they will be bought from retail dealers in different parts of the country and sent to Washington. These tests will be made public in the interest of the people, and from the method to be followed in obtaining the samples, the brewers will not be able to render the tests nugatory by preparation.

An Argument for Vegetarians.

The heavy work of the world is not done by men who eat meat. The Roman soldiers who built such wonderful roads, and carried a weight of armor and luggage that would crush the average farm hand, lived on coarse brown bread and sour wine. They were temperate in diet, and regular in exercise. The Spanish peasant works every day and dances half the night, yet eats only his black bread, onion and watermelon. The Smyrna porter eats only a little fruit and some olives, yet he walks off with his load of a hundred pounds. The coolie, fed on rice, is more active, and can endure more than the negro fed on fat meat.

Some Quack Remedies.

Dr. Davenport, the analyst of the Massachusetts State Board of Health, states that of twenty advertised cures for the opium habit, all but one contained opium. He examined a large number of "temperance drinks," and found all to contain alcohol, and one as high as 44.3 per cent. The majority contained over 20 per cent. A preparation analyzing 41.6 per cent. was claimed by a manufacturer "to be purely a vegetable extract."

A New Port Physician.

Governor Beaver has appointed Dr. William H. Randle, of Jenkintown, physician at the port of Philadelphia, in place of Dr. Henry Leffman, whose commission expired October 1st.

Dr. Randle is a graduate of Jefferson Medical College, and is about 35 years of age. He has never held any public office. He was appointed by President Hayes to the Medical Commission which visited Memphis in 1878, during the yellow fever epidemic. The office yields about \$2800 yearly.

Pills in Shells.

A correspondent sends us the following: After reading the item on page 63 of the June number, "Didn't want the pills in shells," I was reminded of a case I had some few months ago. The customer was an oldish lady who had worked herself all out on a farm, situated about a mile out, and she is one of the "fussy" kind. She came into my store just after I returned from dinner, with a prescription as follows:

R Salicine.....gr.xxiv
Pv. cinchona rub.....gr.xij
M.—Put into capsules No. 24.
Sig.—One before meals.

I prepared the medicine according to orders. The lady paid and went home. About five o'clock she came in all out of "wind," and asked where Dr. — was. I informed her that he had gone out of town and wouldn't be back for several hours. "Oh, dear, what shall I do? I must see him at once!" I asked her what the trouble was, if any one was hurt? "Why," said she, "I swallowed one of those little glass boxes you put my medicine up in, and I am afraid it will kill me, and what shall I do? The doctor said he would have it fixed so I wouldn't taste it, and I thought it was pills, and so I took one and, after I swallowed it, I picked up another one, and as soon as I pinched it a little in my fingers it all flew to pieces, and then I found out

it was glass. Now, why didn't you tell me to turn the medicine out of those glass boxes before taking it? But you didn't, and as I can't see very well, I have swallowed the glass and all, and you don't know how my stomach feels; it will surely kill me. Oh, what shall I do, and can't you give me something? Oh, dear, how my stomach burns and aches! You ought to be put in jail for giving people medicine in little glass boxes and calling them pills. Did you make a mistake, or did you try to kill me? Oh, dear, give me something quick, or I shall faint." I finally got her quiet, after hearing such talk as this for half an hour, and then I was able to explain what those little glass boxes were for, and what they were made of, but finally had to dissolve one to satisfy the old lady that there was no glass about them at all, and that she would not die, and that there was no harm done, etc. She replied that those were the funniest things she ever saw, and upon that she went home, feeling better. Since that time I have explained to every old lady that wanted capsules what capsules were made of, etc., before letting them go out.—*American Druggist*, August, 1887.

Yellow Fever or Dengue.

Dr. Wall, President of the Tampa (Fla.) Board of Health, telegraphed to the Marine Hospital Service on October 1st that the disease prevalent there is unquestionably yellow fever, despite a popular belief to the contrary, and that the contagion has spread to every part of the city.

The President of the Florida State Health Protective Association has telegraphed that citizens and physicians of Tampa are not satisfied that the disease is actually yellow fever, and are anxious that Dr. John Guitéras should be ordered to Tampa to determine the question.

Surgeon-General Hamilton has ordered Dr. Guitéras to Tampa as requested, and has taken steps to provide a temporary hospital and to furnish abundant supplies of disinfectants.

A Case of Purpura with Circinate Lesions.

In the October number of the *Journal of Cutaneous and Genito-Urinary Diseases*, Dr. H. W. Stelwagon reports a case of purpura with circinate lesions, which is illustrated by a very good cut. But one similar case has been recorded up to the present time—a case reported by Drs. Dühring and Van Harlingen in the *REPORTER*, August 3, 1878.

A Drug Clerk Punished.

James A. Stewart, of Wichita, Kan., was sentenced on Sept. 22d to seventeen years and four months imprisonment in the county jail and fined \$20,800, with costs of prosecution, for the violation of the Prohibition law. Stewart was a clerk in the West End drug store, and pleaded guilty to an indictment containing 2080 counts. The punishment imposed on Stewart is the heaviest ever given in the State for violation of the liquor laws.

Cinchona-Growing in Réunion.

Some time ago we reported that efforts were being made to propagate the cinchona tree in some of the French colonies, and that it was confidently assumed that these experiments would be so successful as to render French buyers independent of the London market in a few years' time.

Mr. C. L. St. John, British Consul in the French colony of Réunion, gives some interesting details of the cultivation of cinchona in that island. He states that for some years past the planting of cinchona has absorbed much attention in Réunion; and, although the plantations have hitherto assumed no very extensive development, the results obtained are sufficiently satisfactory.

At Réunion the plantations are made in forests, at a height of about 4000 feet. At this altitude, where there exist no high trees, but merely brushwood, parallel alleys from five to six feet wide are made, as far as practicable in spots sheltered from the winds. These alleys are separated by a range of brushwood, 10 feet thick on each side, which serve to protect the young cinchona plants against the violent winds so common in Réunion. Holes are then dug, at a distance of 15 feet apart, 20 inches in diameter, and the same in depth. They are then filled with the earth that has been dug up, and to which some mould is added. This mixture forms, at the surface of the soil, a convexity, into the middle of which the young cinchona plant is placed; and the alley, after a few showers of rain, is soon brought to a level.

In a soil thus prepared the young plant experiences no difficulty in its growth; but when it has attained a height of 1 foot 6 inches, care must be taken to cut the roots of the adjoining brushwood, which may have found their way into the space reserved for the cinchona, in order that the plant may meet with no impediment in the course of its development.

At the end of seven or eight years, the

plants have a diameter of $3\frac{1}{2}$ inches, and are ready to be worked.

The following is the manner in which the bark is prepared: Towards the month of October—that is to say, when the sap resumes its ascensive movement, and the bark is more easily detached—the plants are cut at about 2 inches from the ground. The bark is then taken off and put in the sun to dry. From the stump that remains there soon spring a great number of young shoots, which, when they have in their turn attained a certain size, should be lopped off, only leaving the number of sprigs which the stump is able to feed conveniently. These sprigs have a rapid growth, and, at the end of another period of six or eight years, a new crop is ready.

In this way the cultivation of this produce, once planted, can be continued almost indefinitely, and at little expense. The consul thinks that it is evident that the means employed in Réunion for the cultivation of the cinchona are very practical, and far more economical than those in vogue in Java.

Although the Réunion plantations are as yet only on a limited scale, the results are such as to induce their extension. Hitherto, experiments have only been made by the local government on the Crown lands, and by a few wealthy planters. Lately, the Government sold a certain quantity, which brought a little more than 2 francs per lb. in the market.

The manager of the Crédit Foncier Company has also expressed great satisfaction at the results he has obtained, and he will shortly sell over 200 lbs. of cinchona planted in 1879. This year he expects to have a new crop from trees planted in 1880; and so on.

It may be stated that the stumps of the plants that were cut in October last are already covered with young shoots.—*Chem. and Druggist*, Aug. 20, 1887.

—Dr. W. T. Councilman, of Johns Hopkins University, will address the Philadelphia Pathological Society at the Semi-annual Conversational Meeting, Thursday, October 27, on "Further Investigation on the Malarial Germ of Laveran."

Members of the College of Physicians, County Medical Society and Obstetrical Society, are invited to be present.

—In a communication to the *Société de Biologie*, M. Chouppé reports success in the treatment of diarrhoea with antipyrine, in doses of fifteen grains.

Items.

—Dr. Sommer, an Hungarian physician, obtained the consent of the mayor and president of the Board of Health of New York to conduct experiments with the virus of hydrophobia upon the dogs collected by the dog-gatherers and taken to the pond. The Society for the Prevention of Cruelty to Animals have, however, interfered, and require the doctor to obtain the authority of some medical college or university in the State before they will permit him to conduct his investigations. We should think that an application, properly made, to any of the medical institutions of the city, would be followed by the granting of the requisite authority.—*Science*.

—We learn that summonses have been issued against twenty druggists in Chicago for violating the city ordinance governing the sale of liquor. One of these, Mr. Secord, has already taken out a saloon license of \$500. Interesting developments are looked for, as the collector intends to enforce the ordinance, which he interprets also as prohibiting altogether the sale of "bottle goods," such as "Duffy's" and "Belle of Bourbon," without a saloon license. We have repeatedly warned druggists of impending prosecutions, and those who may be proved guilty of violations are entitled to no sympathy. The registration of sales has been much neglected of late; the legal penalty will sooner or later follow.—*The West. Druggist*, August, 1887.

—Muddy water is made clear in the following manner: Dip a filtering-paper in a solution of ferric chloride (43 per cent.), and another paper in a saturated solution of sodium carbonate, and dry. Place a piece of the ferric chloride paper in the muddy water, then a piece of the sodium carbonate paper; a precipitate of ferric carbonate is formed which clarifies the water. The water thus treated can be filtered through a funnel whose neck is filled with a piece of sponge. It will be as clear as crystal, and can be used as drinking water.—*Chem. and Drug.*, July 30, 1887.

—A writer in *Harper's Bazaar* makes a pretty close diagnosis for a layman, as to what ails the modern girl, at least a good many of her. It is well deserving of record as an *indicatio causalis* in the disease which is so often the despair of the doctor. "The modern girl hardly knows what she wants, whether it is the higher education, an æsthetic wardrobe, love or fame. She plays tennis and progressive euchre, and flirts and does Kensington work and reads Herbert

Spencer, and very often writes; she dabbles in music and talks theosophy, and if there are more things in heaven and earth than are dreamed of in her philosophy one questions what they can be. Withal, she is as restless as the wind. She does not love the quiet of home; she lives on excitement; she goes to Europe, to the springs, the mountains, the theatres, the receptions, if she can get there, or to the modiste; she can always fall back upon clothes as a diversion, and, when everything else fails, she has nervous prostration and a trained nurse. In fact, the chief trouble with the modern girl, be she rich or poor, is that she either does too much, keeps her nerves on the strain, and by and by goes to the other extreme, and does literally nothing but consume drugs, talk of her ills, and consult the Christian scientists; or she has no real interests, fritters away her time in shallow pursuits, becomes pessimistic and dyspeptic, dissatisfied with herself and all the world; cries and questions if life is worth living, and feels especially blue on holidays. The remedy for all this is, perhaps, an object in life; those who are well and unselfishly occupied do not question if life is worth living; they know it is; and whether they are busy in the shoe factory, behind a counter, at the fireside, in the kitchen or the dining-room, so long as they are busy and not shirking or reaching forward for something more congenial, and neglecting present duty, their minds are at rest and uninvaded by despondency. One of the best remedies for depression of spirits is the effort to bestow happiness; it has been known to prove effectual when all other methods have failed; when novels and new gowns and cod-liver oil and bovine and bromide; when admiration and flattery, are no more serviceable than an abracadabra or any heathen spell. Melancholy or other ills of this nature are the direct result of a too strong egotism, and an absorbing interest in others is a safe and agreeable medicine, and is usually the last thing a modern girl tries."—*Boston M. and S. Journ.*, Aug. 11th, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Oct. 9, 1887, to Oct. 15, 1887:

Lieutenant Colonel Chas. F. Alexander, Surgeon, relieved from duty as Attending Surgeon and Examiner of Recruits at St. Louis, Mo., and ordered for duty at Ft. Meade, Dak. S.O. 235, A.G.O., Oct. 8, 1887.

Capt. F. A. Cunningham, Assistant Surgeon, died Oct. 12, 1887, at Ft. Lewis, Col.

SOME PRACTICAL POINTS IN CONNECTION WITH CATARRHAL FEVER.

BY SOLOMON SOLIS COHEN, A.M., M.D., OF
PHILADELPHIA.

To the classic paradox of the prognosis of catarrhal fever, "the most fatal and the least fatal of all diseases," may be added a similar characterization of its diagnosis—at once, the easiest and the most difficult. The picture of a typical attack of influenza is so striking, that to mistake it were almost impossible. But typical attacks are by no means as frequent, save in periods of widespread epidemics, as the irregular, ill-defined, and misleading manifestations, which occur without attracting prominent professional or popular attention; epidemically, it is true, but at those periods of changeable and uncertain weather, when "catching cold" is the ready explanation of a coryza or of a bronchitis. The cold is treated with household remedies, or somebody's patented cough-mixture, or not treated at all. Very often, recovery ensues in the natural course of events. Quite frequently, however, especially in strumous children or adolescents, an insidious catarrhal pneumonia is developed, with all its evil consequences.

When these cases of subacute or chronic broncho-pneumonitis come under observation, their origin is usually so remote as to be obscured, nor is the question any longer of practical therapeutic importance. But when

the case comes under the physician's hands at an early period of its progress, it is of considerable moment to the patient's future, to recognize that we are dealing with a systemic process requiring supporting treatment, and not a mere local catarrh. Cases of pronounced pneumonitic character, whether lobar or lobular, need not here be discussed, either diagnostically or therapeutically, save to express the opinion that quinine should not be omitted in their treatment. It is the cases of apparent simple bronchitis that may mislead the diagnosis. Here, then, the amount of respiratory distress, out of all proportion to the physical signs discernible upon percussion and auscultation, the persistent cough, the excessive sense of constriction in the chest, the numerous unpleasant sensations referred to various portions of the respiratory passages, yet for which no adequate objective explanation can be found; the chilliness, the irregular fever, the rheumatic pains in back and limbs, the unaccountable depression, the exquisitely painful headache, the cutaneous hyperæsthesia, often the precedent history of a coryza,¹ sometimes coincident conjunctivitis, occasionally supra or infra-orbital neuralgia,—many or all of these phenomena being easily elicited upon close observation or questioning—will inform the careful physician that he has more than an ordinary cold to deal with.

But it is when the catarrhal symptoms referable to nose, throat, or chest, are slight

¹ While the ordinary case of catarrhal fever, not rising to the importance of a well-marked influenza, presents the successive symptoms of coryza, bronchitis, diarrhœa—the order is not rarely reversed, diarrhœa being the first symptom and coryza the last.

or unnoticed, that the greatest liability to error in diagnosis will occur. A case recently seen will furnish a more concrete picture of this class, than would a more general description.

Typhoid fever is prevalent in a certain section of the city. A young man, residing in this neighborhood, overworked, rather anæmic,—just in condition to furnish a good subject for typhoid poisoning,—complains of excessive lassitude and weariness for a few days past; he has an intense headache, and considerable pain in the back and limbs; he has had epistaxis; his tongue is covered with a white fur except at the tip, which is red; he has a slight cough; the night previous he had chilly sensations off and on for several hours, since which he has felt rather feverish. He has a temperature (morning) of 101.5° , a pulse of 100 respirations 28. He has not had diarrhœa, there is no tympany, no gurgling, no rose-spots. There is an area of dulness at the left base of the chest, about three fingers' breadth in extent. A friction-sound is perceptible at the upper border of this area, and below the friction-sound the lung-sounds are somewhat muffled. Scattered over both lungs are irregular areas of large and small moist râles, with somewhat bronchial breathing here and there. Pleurisy and bronchitis are not unusual accompaniments of typhoid fever—it may be too early for rose-spots, the temperature is not too low for a mild case, the absence of diarrhœa counts nothing against the diagnosis—it is evident that caution is necessary in coming to a conclusion.

Yet the tongue is not a characteristic typhoid tongue; the physiognomy is not that of typhoid; there is no enlargement of the spleen; the weakness of circulation, the depression, the headache, are greater than we would expect in a case of typhoid fever so mild in other respects; there is no typhoid odor to the breath; trifles, intangible some of them, indescribable many of them, are conjoined with a history, elicited on close inquiry, of a cold in the head preceding the epistaxis, the latter having been due to violent efforts in blowing the nose to rid it of accumulated secretions; with the confession of occasional distress in breathing, and the evident fact of bronchial catarrh and its pleural analogue; at least making the question of catarrhal fever an open one. The occurrence of profuse diarrhœa, the following day—which might be typhoidal, though the discharges are watery without being the characteristic pea-soup stools, and have not the odor of the discharges of enteric fever—is coinci-

dent with a fall of temperature to the norm. The pulse sinks to seventy-two. Improvement in the constitutional symptoms soon follows. The temperature rises again to 100° , but remains elevated for only twelve hours. The diarrhœa is readily controlled. The bronchial and pleural troubles disappear gradually in due time, and the patient is perfectly well in a week.

A provisional diagnosis of typhoid fever would not have been blameworthy in the first few days of such a case, yet more than the mere doubt was not entertained in this particular instance, for the reasons given; probably because the writer's attention has by the accident of early experience been strongly drawn towards this particular group of cases of catarrhal fever.

There are many cases in which the intestinal symptoms are early and more pronounced, in which the course of the illness is more prolonged, in which often, a malarial complication is present, giving a still more close resemblance to typhoid fever in other respects, and the writer believes that these cases are a not infrequent source of erroneous diagnosis. He has, however, seen cases of genuine enteric fever, in which the diagnosis has eventually not been at all doubtful, in which he has been convinced that catarrhal fever immediately preceded the development of typhoid fever, or that the two have overlapped, giving rise to some liability to confusion in the early days of the latter affection. If, therefore, there exists the slightest doubt in the mind of the attendant, it is certainly the part of wisdom to put the patient upon liquid diet, and institute the necessary safeguards against the spread of infection.

The drugs which in the writer's experience are most useful in the treatment of catarrhal fever are quinine, salicylic acid, ammonium and the terebinthinates. Cinchonidine salicylate is a favorite preparation, prescribed in capsules containing five grains each, from fifteen to thirty grains *per diem* being administered, according to circumstances. Terebene, ammonium chloride, ammonium carbonate, ammonium salicylate, or aromatic spirits of ammonia, is given for the bronchial or pulmonary conditions; the choice depending upon the extent of lesion, the condition of the circulation, the presence or absence of rheumatic diathesis. Turpentine stupes are applied to the chest, when necessary, or an embrocation, the familiar Stokes' or St. John Long's liniment, is employed. This measure is resorted to more especially in

children, and if supervention of capillary bronchitis is feared, active counter irritation is instituted. Diarrhoea is controlled by opium, and if there be, in children especially, an amount of cough or pain sufficient to disturb rest, or to demand treatment on its own account, opium is employed in preference to all other sedatives or anodynes. A supporting diet, with a fair amount of alcohol, increased to point of tolerance, in cases of great depression, and especially in the very old or very young, is an important element in the management of the case. Pleuritis and other complications are to be managed on general principles.

219 S. 17th Street.

CARBOLIC ACID IN RADICAL CURE OF HYDROCELE.

BY D. H. STRICKLAND, M.D., ERIE, PA.

About four months ago there came to my office a young unmarried man, aged 26 years, complaining of some scrotal trouble, which he said he had first noticed about four years previous, and of late it had become so large as to cause him pain and great inconvenience in locomotion. An examination revealed an enlarged condition of the left side of the scrotum caused by a chronically enlarged left testicle (the result of former gonorrhœal orchitis), and a hydrocele. The patient's business matters at that time would not admit of an attempt at radical cure, and hence temporary relief was afforded by drawing off a full half-pint of straw colored fluid with trocar and canula.

I did not see him again for six days, when he again entered my office, complaining of the old trouble, saying that it was as large as ever. I was inclined to doubt this statement, so short a time having elapsed since the former operation. But an examination verified the truthfulness of his statement. I then informed him that the proper thing to do was to attempt a radical cure, to which he readily consented, after I had explained to him the nature of the procedure. The following day I visited him in his room, again using my trocar and canula, drawing off fully as much fluid as before, after which I injected about two drachms of a 10 per cent. solution of carbolie acid, the most of which I allowed to remain in the sac. He remained in bed the most of the time for one week on low diet. An active inflammatory action followed, which was sufficient to obliterate the sac and cause a perfect cure, without any untoward symptoms, and at this writing, some

five months after the operation, no evidence of former trouble exists.

EXTRA-UTERINE PREGNANCY—REMOVAL OF THE FŒTAL BONES THROUGH THE RECTUM AFTER NINE YEARS.

BY L. M. GATES, M.D., SCRANTON, PA.

About 9 A. M., August 2d, 1887, I was called to Mrs. N., aged 41, suffering with severe pain in the rectum, following defecation. She informed me that she had passed some fresh blood with the stool which otherwise was as usual, and that she had formerly been troubled with piles. Thinking that it was an attack of painful hæmorrhoids I gave a suppository of opium and iodoform. At noon I was again summoned as pain seemed worse, and she had a feeling as though something wanted to pass, but could not. On introducing my finger into the rectum it came in contact with a hard, sharp edged, rounded body feeling something like an egg-shell, which was with difficulty extracted, and proved to be the squamous portion of the temporal bone of a fœtus. Thinking there might be more of the same where that came from, I introduced my finger again and found as far up as I could reach a hole in the anterior wall of the rectum filled with fœtal bones. Finding attempts at extraction very painful, I gave an opiate and put the patient to bed until help and anæsthetics could be obtained.

Cocaine was then tried first in a four per cent. solution, but it was useless, as it did not relax the parts nor relieve the pain. Ether was then given, which did both, and I removed the entire skeleton of a fœtus by the fingers, aided with forceps. These bones were apparently encysted in Douglas' pouch, as the tumor could be distinctly felt posterior to the uterus, pushing forward the os uteri which felt normal except for fixation. After removal, the cavity was washed out with a 1 to 1000 permanganate solution, and I ordered a suppository of ext. opium gr. j, and iodoform gr. ij, if required for pain. The next morning pulse and temperature were normal, but in the evening the pulse was 120 and temperature 103°. The rectum was again washed out with 1-1000 solution pot. permang., and quiniæ gr. ij, and antipyrine gr. iij given every four hours.

Aug. 4th, temperature 102°, pulse, 120. She had a passage of matter from the bowels and some pain. The bowels were slightly tender and tympanitic. Used injection of permanga-

nate solution, which gave considerable pain. From this time the pulse and temperature gradually improved until the 8th, when both were normal. On account of the pain they produced the injections had to be given up after the 6th. On the 7th she had a natural passage, and on the 8th two normal stools without either pus or blood. On the 10th she was sitting up, and on the 16th was out of doors, feeling well but weak, and has since been in better health than for years past, being free from a chronic diarrhoea with which she had suffered for three years.

It is pleasant to call attention to the extremely short time it took for the sac to close down and heal up. The previous history of the case is also interesting and instructive.

The patient is the mother of one child, 22 years old, and has had no miscarriages. Nine years ago she presented some of the symptoms of pregnancy, enlargement of the abdomen, irregular and scanty menstruation, but not entire suppression. During the summer she had frequent attacks of cramps and sinking spells, with persistent pain in the abdomen, so that she was obliged to keep her bed for about three months. She had also what she called ulcers break on the womb and bearing down pain and pressing against the back and through the hips. A woman physician professed to put the womb up in place, and treated her for some time, relieving these symptoms. On consultation between this physician and one of the oldest in the place, they pronounced her pregnant at seven months, while another said she was not. At about time for delivery she experienced pain for an entire day, with some hemorrhage, but as the pains passed off towards night, no physician was called. From this time she was regular, and gradually diminished in size until in three months her enlargement was not noticeable. Then for six years she enjoyed fair health.

About three years ago she was sick for nearly a year with what her attendant at first called malarial fever, and then intermittent fever, followed up by inflammation of the bowels, with continuous severe pain and tympanitis for two months. This was followed by discharges of matter through the bowels, and what she called "ulcers on the womb." Since then she has had poor health, dyspepsia, chronic diarrhoea and frequent attacks of cramp in the stomach.

In the light of her recent delivery, her malaria and intermittent fever was probably the result of blood-poisoning from suppuration of the sac, which finally caused inflammation of the pelvic peritoneum, with sub-

sequent rupture into the rectum by which the soft parts of the fœtus were gradually discharged through the small opening, causing chronic diarrhoea. As the sack contracted, the bones finally ulcerated through into the rectum and nature, aided at the close by art, succeeded after nine years in ridding itself of the foreign body.

126 Washington Avenue.

ON THE PROLONGED EXPIRATION OF INCIPIENT PHTHISIS.

BY THOS. J. MAYS, M. D., PHILADELPHIA.

Professor (adjunct) of Diseases of Chest in Philadelphia Polyclinic.

More than fifty years ago Dr. James Jackson, Jr., of Boston, first called attention to the fact that a prolonged expiration constitutes one of the most prominent features in the first stage of pulmonary consumption. This has been repeatedly confirmed by other observers, and since I regard it as one of the most interesting physical signs in the study of chest diseases, both in regard to its import and to its mechanism, it has occurred to me to devote a few thoughts to its study, and thereby, perchance, add something which may aid in elucidating its important character.

The primary morbid condition in pulmonary consumption is consolidation, and prolonged expiration frequently marks the very first step in the series of successive pathological changes which lead from healthy lung to confirmed infiltration. If it thus stands alone, *i. e.*, if it is unaccompanied by diminished percussion resonance, or by any other abnormal physical sign, its diagnostic significance, and a determination of its true nature are of vital importance. In listening to a prolonged expiration, the first thought which rivets the attention of the observer is as to the reason why the sound of expiration should be louder, or of a higher pitch than that of inspiration. For if, as is correctly assumed, it is produced by the solidification and expansion of the pulmonary tissue and a thickening of the walls of the adjacent bronchial tube, which cause a certain degree of resistance to the egress of air, why should not the air during inspiration meet with the same resistance in going through the same tube and produce the same pitch as that which is heard during expiration? It becomes still more incomprehensible when we seek to explain it in accordance with the current teaching of physiology, that inspiration is an active,

and expiration a passive process, for if other things are equal, an active process should exert more power than a passive one; therefore the air in passing the same resistance or obstruction should at least produce a sound of greater intensity when propelled by an active than by a passive force. It is needless to state that the very reverse holds true, both in the normal and in the diseased lung.

On inquiry it will be found, however, that the respiratory organs during expiration display more energy than is generally assumed; in fact, that there is as much activity about expiration as there is about inspiration, as is demonstrated by the following anatomical and physiological considerations. The trachea and bronchi are abundantly supplied with transverse and longitudinal muscular fibres, and the experiments¹ of Prof. Chas. S. Roy and Dr. Graham Brown prove that these muscular structures subserve an important purpose in the economy of respiration. These gentlemen have shown that, "in the curarized dog, stimulation of one uncut vagus with an induced current causes contraction of the bronchi of both lungs, the contractions (with some exceptions) being usually powerful; that stimulation of the peripheral end of one cut vagus always causes a much more powerful contraction of the bronchi of both lungs than when the uncut nerve is stimulated with the same strength of induced current. We found further that stimulation of the central end of one cut vagus—the other being intact—usually causes contraction, but never so powerfully as when the peripheral end of the cut nerve is stimulated; that frequently, and especially in non curarized animals narcotized with ether, stimulation of the central end of one cut vagus, the other being intact, causes a powerful expansion of the bronchi; that the extent of the changes in calibre so produced vary greatly. On stimulation of the peripheral end of the cut nerve the bronchi often appear to close almost completely, and contractions equal to one-half or one third of the previous diameter are frequently met with; and that the expansions met with under certain conditions are as marked in extent as the contractions."

These experimental data therefore not only show that the power of expiration is largely assisted by the powerful contraction of the muscular fibres of the bronchial walls, but further, that these structures possess a mechanism whereby the process of inspiration is materially enhanced. And when we

consider these facts in connection with the manometric observations² which have been taken during respiration, especially during forced respiration, both in animals and in man, which show that the pressure of expiration is nearly twice as great as that of inspiration, it becomes quite evident that expiration must be of a higher pitch, or of greater intensity because more force is exerted, and less time is employed, in emptying than in inflating the respiratory organs. This then being established, the mechanism of a prolonged expiration and of a bronchial respiration comes fully into view. If the air during respiration encounters an obstruction in a bronchial tube, due either to a tumefaction of the wall of the tube, or to a compression of its lumen through surrounding infiltration, we can easily see that the pitch of expiration must always be relatively higher than that of inspiration. Of course it must not be forgotten that both the sounds of inspiration and of expiration are conducted to the surface of the chest with greater facility in partial or complete solidification of the pulmonary tissues than they are through normal lung structure.

If then a prolonged expiration is an indication of pulmonary infiltration, however slight, around a bronchial tube, and is produced on the same principle as that on which bronchial respiration is produced—and, indeed, it may be said to be a forerunner of the latter, whose gravity is clearly acknowledged by every one—it is needless to say much on the profound importance of truly recognizing a prolonged expiration as a diagnostic sign in the early stage of pulmonary consumption. For if bronchial respiration is of serious significance, prolonged expiration points more eloquently in the same direction, because it frequently exists earlier.

1829 Spruce Street.

—WHERE HE GOT THEM.—A gentleman entered a phrenologist's office in Boston and asked to have his head examined. After a moment's inspection the professor started back exclaiming: "Good heavens! you have the most unaccountable combination of attributes I ever discovered in a human being. Were your parents eccentric!" "No, sir," replied the all-round character, meekly, "but my wife is. You needn't pay any attention to the larger bumps, sir."—*Burlington Free Press*.

THE CONJUGAL QUESTION.

BY MADANA F. DE HART, M.D., JERSEY CITY,
NEW JERSEY.

The article from your correspondent, Janet E. Rees, is full of interest, first on account of its importance, and second, because it comes from a woman. As she suggests, women physicians receive a kind of testimony which has not been freely given to men, or if given, for some reason has not received the attention it deserves.

Finding themselves unequal to the demands made upon them, women modestly conclude that they are abnormal, and not until after years of suffering do they venture to think even, that possibly these demands have been unreasonable and contrary to nature.

When their health has failed they have taken tonics, stimulants and anodynes; they have submitted to local treatment of all kinds; have been scarified, leeches and cauterized; worn pessaries of all conceivable shapes and sizes, and as a last resort have consented to have the uterus and ovaries removed as the only way to obtain peace. Such cases are becoming so frequent that it is the duty of all to inquire into the causes which produce these results, and if possible prevent diseases which are so difficult to cure. Cazeaux quotes M. Coste as saying that there are natural and entirely spontaneous epochs for the maturation and discharge of ova, and there are others which may be styled artificial, because it is possible to produce them by artificial means, chief among which he mentions the solicitations of the male.

All text books agree in saying that one of the many benefits arising from pregnancy is that the ovaries have rest. Do the ovaries often have rest during pregnancy and lactation, or are they constantly stimulated to an unnatural activity by the cause referred to? and may not this stimulation of the ovaries be one cause of the persistent nausea and vomiting of pregnancy, as well as of abortions? and is it not reasonable to suppose that the menses appear during lactation earlier on this account?

D. T. G. Thomas, in his *Diseases of Women*, gives sexual indulgence among the causes of acute metritis, chronic cervical metritis and endo-metritis, and gives pain during coition among the symptoms of each disease mentioned. He says, in speaking of chronic cervical metritis, "sexual intercourse during the existence of this disease must necessarily be productive of evil, and should

be interdicted. There is only one method, as a general rule, by which this can be accomplished, and that is by the separating of husband and wife. If this is impracticable, let an injunction of excessive caution be substituted for total abstinence, which will be most certainly disobeyed."

In his article on chronic corporeal metritis, he quotes Dr. Tilt as saying: "It is useless to disguise the fact, connection has a downright poisonous influence on the generative organs of some women;" and then says: "I cannot believe that the Almighty has ordained a function as essential to the perpetuation of our species, which has a downright poisonous influence on the generative organs of a healthy woman."

Doubtless, the most delicate woman could bear without injury intercourse intended for this purpose, as it would not be required of her either when she was sick, pregnant or nursing, or after the menopause, when the ovaries, uterus or vagina had returned nearly to the condition seen before menstruation was established.

It is to be hoped that this subject may be thoroughly investigated by careful observers, anxious to find out the truth, as it may throw some light on many of the obscure nervous diseases of women.

DILATATION OF THE PUPIL WITH
ATROPIA IN OPIUM POISONING.

BY T. WALLACE SIMON, M.D., OF
PHILADELPHIA.

In the early part of this year I was called to see a case of severe cold, so-called, attended with violent neuralgia of the fifth nerve. The case had the day before been under the treatment of a medical friend, an oculist, who had had occasion to dilate the pupil. I found the pupil very widely dilated, so that it was impossible to use the eye, and the light was very painful.

In the treatment of the case I administered in the first dose, with other remedies, one-quarter of a grain of sulphate of morphia. After several hours it seemed to have no effect whatever, and the pain still remaining almost unbearable, I gave a hypodermic injection of one-third of a grain of morphia sulphate in the arm. After four hours there was still scarcely any alleviation of the pain, and I repeated the same injection.

I am positive from a thorough knowledge of the case, that my patient was not addicted to the use of morphia or any other anodyne,

and the remarkable tolerance of the drug shown by him somewhat puzzled me; and the only way that I was able to account for it was on the supposition that it was due to the antagonistic effect of the atropia used for the purpose of dilating his pupil.

The great tolerance of morphia in this case recurred to my mind sometime later while reading of some cases of opium poisoning, and it occurred to me that it would possibly be a very proper procedure to rapidly dilate the pupil with atropia in cases of opium poisoning, as a more direct and rapid method of antagonizing the action of the morphia upon the brain centres.

If the narcotic effects of opium act so powerfully upon the basic centres of the brain, and through the third nerve contracts the pupil, would not a rapid dilatation of the pupil by the antagonistic effect of atropia, force a reversal of the action of the opiate backward along the course of the nerves of the eye, directly to their deep origin in the floor of the fourth ventricle where the opiate expends its force, and there antagonize the effects of the drug in the basic centres of the brain, where alone doubtless its effect endangers life?

This seemed to me a very reasonable supposition, and when not long since I was called to a case of accidental opium poisoning I put this theory to a practical test.

The case was not a very severe one, most of the opiate being removed from the stomach by an emetic before complete absorption of the laudanum had taken place. And though the usual remedies and procedures required in such cases were resorted to, the recovery and reaction from stupor to wakefulness was so rapid after dilatation of the pupil with a strong solution of atropia sulphate, that I feel justified in the belief that it was due in great measure to the latter; and the backward action, so to speak, of the atropia along the course of the nervous circle, beginning with the branches of the infra-trochlear nerve supplying the conjunctiva, thence through the nasal branch of the ophthalmic (of which the infra-trochlear is a branch), through the ophthalmic division of the fifth to the Casserian ganglion, thence to the deep origin of the sensory root of the fifth; which, according to Clark, lies in the gray tubercles of Rolando at the lower part of the floor of the fourth ventricle, and there probably by inter-communicating fibres with the deep origin of the third nerve (branches of which supply the circular or sphincter muscular fibres of the iris and contract the pupil), serve to antagonize the narcotic effect

of the opium upon it, which has caused the contraction of the pupil.

I have not had another case since in which I could repeat and verify this treatment, but believing it a valuable point in the treatment of such cases, I submit it to the profession for their verdict, hoping it may prove of value, and that they may be able to corroborate my experience on this point of treatment.

412 S. Broad Street.

PREGNANCY COMPLICATED WITH HYDROPERITONEUM.

BY WILLIAM B. DEWEES, OF SALINA, KAN.

On Friday, September 23, 1887, I was summoned to meet in consultation Dr. Sanders, of Niles, Kansas, at the house of Mr. George Gallion, twelve miles north-east of this city—Salina, Kansas—whose wife was not expected to live. Arriving at the house at 4 P.M., Dr. Sanders gave the following history of the case:

Mrs. Gallion is thirty-eight years old, mother of eight children, of good family history, and always enjoyed good health prior to the present ailment. The first week in February, 1887, she missed her catamenia for the first time in several years. Seven weeks later she flowed for four days, the flow being in time, quantity, and color identical with her normal menses. Six weeks after this, she flowed again, but this time the flow lasted only three days, and was much less in quantity and color than at her normal periods. Since then she has had no show. Save these two flowings, her condition since February, 1887, has been similar to that in her previous eight gestations, until about three weeks ago, when she noticed a slight constant pain, extending from the linea alba about three inches below the ensiform cartilage along the lower border of the chest, on the right side, to a point under the right scapula. This pain slowly and steadily increased until a week later, when Dr. Sanders was called for the first time. She was partially relieved by anodynes; but it now was noticed by both the patient and Dr. Sanders, that her abdomen was rapidly enlarging to enormous proportions, while, in addition to her suffering from the pain above described, she was compelled to assume the sitting posture, so great was the pressure on the diaphragm. This was her condition when I was called.

We found the patient in a sitting posture in bed, with short and impaired respiration, with dilating nostrils, a semi-jaundiced appearance of skin and conjunctivæ, some-

what sunken features, an anxious look in her eyes, and slightly cyanosed lips. She had a full pulse, and an enormously enlarged abdomen, everywhere very tender to the touch, so much so that it was with great difficulty and with considerable suffering on the part of the patient, that an examination was effected.

The diagnosis of *pregnancy*, complicated with *hydroperitoneum*, was agreed upon. The treatment to be pursued was of vital import, her condition was a precarious one, the fluid collecting so rapidly that active measures must be taken. Twenty grains of calomel were given immediately, followed by one-sixth grain of *Clutterbuck's* elaterium hourly, until four pills were taken. The bowels now began to operate, and about a gallon of fluid was discharged per rectum during the night. At about two o'clock A.M. she was taken with labor pains, Dr. Sanders was sent for, but before he reached the house, a healthy fully developed child was born—finger and toe nails, eye lashes, etc. being as fully formed as any child of full term I ever saw. She was a great surprise to all, as it was expected, from the history of the case, that she would go until the first week of November.

Being thus greatly relieved from distension and pressure, the mother continued doing remarkably well, but in three days after it became manifest that the fluid was again rapidly increasing, and on the fifth day after her delivery her condition had really grown even worse than the day preceding labor. I was again hastily summoned, to come prepared with the necessary instruments for tapping her.

When I reached the patient, it was apparent that paracentesis abdominis was the only means of prolonging, and probably, of saving her life. A sheet was at once placed around her body, over the abdomen, crossing on the back, and one end of it was taken by Dr. Sanders and the other by my associate, Dr. F. B. Browne, who made firm traction so as to keep up the unilateral support. After catheterizing the bladder, I now took the trocar and canula, and selecting a point in the linea alba about three inches above the symphysis pubis, pushed it through the abdominal walls. Removing the trocar, a full stream of water flowed through the canula, until over four gallons were removed. An adhesive plaster over the aperture, after removal of the canula, completed the operation. The patient at once gave evidence of a hopeful future, and has at this date, one week after the operation, made a happy recovery, while the child is prospering equally well.

HOSPITAL NOTES.

MALARIAL NEURALGIA.

Reported by M. HOWARD FUSSELL, M.D., Assistant Physician to Medical Dispensary of the University of Pennsylvania.

Two cases of malarial neuralgia have recently come under notice in this dispensary which seem worthy of a place in the columns of the REPORTER, especially as both cases were treated previously without benefit.

Case I.—Annie G., thirty-eight years old, married, had for two weeks been suffering with severe pain, limited to the region supplied by the left supra-orbital nerve. There was tenderness over the supra-orbital notch and along the main branches of the nerve. Every day since the pain began she has had a chill followed by fever and sweat. Pain begins at 9 A. M., and continues until 3 P. M. Chill occurs after the pain begins, and sweating occurs before pain ceases. Thirty-six grains of sulphate of quinine were administered in the afternoon of the day of her first visit. The next day but one the patient returned thoroughly cinchonized, but free from pain, chill and fever. She was put on gradually decreasing doses of quinine and increasing doses of arsenic, as a result of which the pain never returned.

Case II.—Barbara S., forty-seven years old, married, for several weeks had severe pain in the region of the right supra-orbital nerve. In addition there was tenderness along the nerve and over the supra-orbital notch. This pain was always present, but occasionally there were severe exacerbations, which began with a chill and were followed by fever and sweat.

This condition had lasted for so long a time that the patient was almost worn out with her severe sufferings. She was put upon three grains of quinine every three hours, together with increasing doses of arsenic. In a week she returned much better. During the latter time she had been cinchonized, and at the time of her visit was free from pain. The dose of quinine was doubled and arsenic continued. In another week she returned almost entirely free from pain. The quinine was gradually decreased and arsenic continued, the treatment resulting in cure at the end of the month.

The nature of both these cases had evidently not been recognized before, probably from the fact that pain was the only symptom complained of. The history of chill and fever was elicited only on careful questioning.

The writer has heard Prof. H. C. Wood announce to his class at the clinic in the University Hospital that nine cases out of ten of unilateral supra-orbital neuralgia are of malarial origin and can be controlled by quinine. The administration of full doses of quinine, twenty to thirty grains daily, in such cases as the above, have usually, in the writer's experience, led to the happiest results, such as have just been detailed.

SOCIETY REPORTS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, September 1st, 1887.

The President, THOS. M. DRYSDALE, M.D., in the chair.

Placenta Prævia Centralis.

DR. ROBT. H. HAMILL presented the specimens and related the history of the case. I was called August 13th, to see Mrs. W., aged 40 years, mother of three children, and now in the seventh month of gestation. During the first and second months she had a slight "show," on three or four different occasions. She then saw nothing until the middle of the sixth month, when she had quite a "gush of blood" during the night, without any pain whatever. She did not consult a physician at this time, as she attributed the hemorrhage to having worked somewhat harder than usual during the preceding day.

Four weeks afterward, which was in the seventh month, she had a repetition of the hemorrhage, losing a much larger quantity. She became quite alarmed, and sent for me. The hemorrhage had entirely ceased before my arrival. I made a vaginal examination and found the external os patulous and the internal rigid. A slight discharge of blood continuing, I requested Dr. B. C. Hirst to see the case with me, to consider the question of inducing labor. We found the patient having a copious flow of blood. The os was slightly dilated and was completely covered by the placenta. The woman had no pain, but was becoming faint from loss of blood. We decided to bring on labor at once. The patient was etherized and the os dilated and three fingers passed through the substance of the placenta. I found the foetus lying across the transverse axis of the brim of the pelvis. I succeeded in bringing down one foot and proceeded to deliver. There was no difficulty until the

head became engaged, and it was with the greatest effort that we were able to extract it. The child was still-born owing to the length of time we were in extracting the head. We then delivered the placenta with ease. The uterus at once became firm and hard.

The points of interest in this case were to me first, the central implantation of the placenta; second, the fact that the hemorrhage began so early in pregnancy; third, the difficulty in delivering the head, which I think was due to the placenta so filling up the pelvis that the diameters were so reduced as to materially retard the delivery of the head.

DR. LONGAKER remarked that the most favorable statistics show from forty to forty-five per cent. of children saved. Hemorrhage early in the pregnancy usually indicates a central implantation of the placenta, and labor should be induced early in such cases. Immediate delivery by traction on the leg is to be condemned. The breech is a perfect tampon, and after one leg is brought through the placenta the case may be left to nature. The hand should not be passed into the uterus, but the placenta should be perforated by one or two fingers and bi-polar version effected. If traction on the leg and rapid delivery be effected, a bad presentation of the head at the superior strait will result, and the cervix will not be sufficiently dilated by the body to allow the head to pass quickly and the child becomes asphyxiated. The average result of rapid delivery is unfavorable. The maternal mortality is from ten to forty per cent.

DR. HAMILL did not think the delivery in his case too rapid. Traction on the leg was made because nature was exhausted and was not able to deliver the child without assistance.

Acute Pneumonia in Utero.

DR. B. C. HIRST exhibited the specimens, and remarked that pneumonia during intra-uterine life is rare, but it has been observed. Dr. Stischen, of Australia (*Brit. Medical Journal*, 1886, ii., p. 860), has reported a case, and Dr. Sigl, of Germany (*Arch. f. Gynäk.*, bd. xv., S. 384), has collected three others. Sigl's explanation is undoubtedly the correct one for this occurrence. If the foetal blood is not properly aerated, the respiratory centre in the brain is stimulated to action by the excess of carbonic acid gas in the blood, and the foetus makes inspiratory efforts, drawing into its lungs amniotic fluid, containing in these cases possibly meconium, and a catarrhal pneumonia is the result,

ending usually in the death of the foetus, either in utero or shortly after birth. These cases are to be distinguished from those in which the foetus draws into its lungs amniotic fluid, mucus and blood during labor. The specimen which I exhibit to the society has the following history: These lungs were taken from an infant which died twenty-two hours after birth, having been cyanosed from the first. The mother had had a large lumbar abscess for the past year, and when she came under my observation in the Philadelphia Hospital, in the sixth month of pregnancy, exhibited all the signs of general septicæmia. She gave birth to her child at the seventh month of gestation. The post-mortem examination of the infant showed no other cause for death except the pneumonia involving both lungs, which must have arisen in utero, as the labor was easy and rapid, and there was no reason to believe that the child made inspiratory efforts during its expulsion. The microscopic slides, which are exhibited, confirm the diagnosis. They show well-marked catarrhal pneumonia.

DR. HIRST also exhibited an

Ectro-Melic Monster.

This foetus, expelled in the fifth month, presents, if one adheres strictly to the classification of Geoff. St. Helaire, only a deformity by numerical diminution, consisting in the absence of the left femur and four toes of the left foot. Its appearance, however, is certainly monstrous, and I have ventured to classify it among the Ectro melic Monsters (ectro-melic, *i. e.*, aborted limb).

DR. J. C. DaCOSTA narrated a case of

Rapid Development of a Fibro-Sarcoma of the Uterus.

The patient came under his care three years ago for catarrhal metritis, the uterus being sharply retro-flexed and the posterior wall being bulged as if an interstitial fibroid were present. These conditions were all cured by the use of sponge tents. About the middle of last May she was attacked with a profuse metrorrhagia, lasting ten or twelve days; fungous vegetations were removed by means of the curette. The June period occurred normally on the 22d, but a recurrence of the bulging in the posterior wall was noticed. She went to the sea-shore, but returned on July 22d, worn out, thin, and with white, anæmic lips. She had had a sanious discharge from the vagina for the last twelve days. Her condition had been diagnosed at the shore as "fibroid and ulcerated cervix." The os was as large as a

five-cent nickel. The cervix was filled with a pulaceous mass which was extruded by the free use of ergot. On July 25th, Dr. DaCOSTA removed, from the body of the uterus, a tumor three inches long by two inches thick—a fibro-sarcoma which had grown inside of thirty days. The patient recovered rapidly.

DR. DRYSDALE thought this very rapid. These tumors were likely to recur.

DR. JOSEPH PRICE exhibited a specimen of

Abscess of Both Ovaries.

In his experience it has been a common condition. He has operated in four such cases within three months. This case had escaped unoperated upon from Birmingham. Pus was present in both tubes. The operation was a complete enucleation without ligature.

DR. PRICE exhibited a "cotton rope" or wick, which he used in the drainage tube. It becomes filled with blood, serum, etc., and is replaced with a clean one, two or three times a day. It keeps the openings clear and favors discharge of fluids.

PHILADELPHIA PATHOLOGICAL SOCIETY.

Stated Meeting, September 22d, 1887.

The President, DR. J. C. WILSON, in the chair.

Thrombosis of the Portal Vein.

DR. W. OSLER presented a specimen of thrombosis of the portal vein, and remarked that chronic obstruction to the blood flow in the branches of the vena porta within the liver, such as occurs in cirrhosis, is probably the most common cause of this rare condition. We not infrequently meet with atheroma in the portal vein and its branches in cirrhosis, one factor in the production of which, as in the pulmonary artery in mitral stenosis, is the heightened blood pressure; to this change the thrombus formation is closely related. At first, and possibly for a long time, mural, it gradually becomes obliterating, and if the collateral circulation is established the patient may live some time, as in a case which I reported in 1882 (*Journ. of Anatomy and Physiology*), in which the vein was represented by a firm fibrous cord. The specimen here shown was taken from a Swede, aged about 45 years, who was admitted to the University Hospital on May 7th, with ascites; as he could not speak English, it was difficult to obtain a history, but we ascertained that he had been

in failing health for some time and latterly his abdomen had become swollen. The swelling did not appear to have come on suddenly. The liver dulness was reduced, the superficial abdominal veins were moderately distinct, and the case was regarded as one of ordinary cirrhosis. He was tapped five times between May 20th and July 14th, and from twelve to fifteen pints of serous fluid removed on every occasion. He was able to be up and about after each tapping, but he gradually became emaciated, weak, finally comatose, and he died July 20th. There were no hemorrhages, and it may be stated that the abdominal veins were at no time more distended than is common in atrophic cirrhosis. The conditions found post-mortem were as follows: fibrous adhesion in peritoneum; atrophic cirrhosis of liver; with thickened capsule; old firm thrombus in vena porta, extending into splenic and mesenteric veins; thickening and patchy calcification of the walls of the portal vessels; great enlargement and induration of the spleen; kidneys indurated; no special changes in thoracic organs. A careful dissection of the abdominal veins was not made, but I am told by Dr. Miall, who made the autopsy, that the peritoneum was very dark and the veins behind the liver very large. The collateral channels were no doubt largely the anastomoses which exist between the peritoneal, mesenteric and lumbar veins and the gastric, diaphragmatic and œsophageal vessels. As in the case of fibroid obliteration referred to, a perfect collateral circulation may be established in occlusion of the portal vein, and the patient may live for months or years. In this instance the thrombus was evidently old, as in places there were calcareous changes. The branches in the liver were filled with soft clots. The gall bladder was full of normal bile. In two other cases of cirrhosis I have met with thrombi in the portal vein, in both instances with thickening and atheromatous changes in the vessel walls, but the thrombi have not undergone such degenerative changes as in this specimen.

Chronic Hypertrophic Cirrhosis of the Stomach.

DR. H. F. FORMAD presented a specimen of chronic hypertrophic cirrhosis of the stomach with gastric ulcer, and colloid change of the mucous membrane. A sailor, aged 38 years, a German, was admitted to the Naval Hospital ten months ago with the symptoms of dyspepsia and occasional vomiting. There had been absolutely no pain at any time and no vomiting of blood. Three months before death he began to have

serious difficulty with swallowing, with œsophageal regurgitation, and though a stricture was sought for none was found. Very curiously for a few days immediately preceding death he swallowed well. Death resulted from starvation. At the autopsy the abdominal cavity was found to contain 52 ounces of straw colored fluid, and showed evidences of old peritoneal inflammation, especially at the upper part, where the organs were massed together into one mass. The stomach was quite contracted, having a capacity of 4 to 5 ounces. Its walls were $\frac{1}{2}$ to 1 inch thick, the thickness greatest at the cardia, and gradually decreasing till within 2 inches of the pylorus, when the wall abruptly assumed its normal condition. The first impression given was that it was a case of cancer, but closer examination showed it to be simply great thickening of the wall with polypoid elevations of the mucous membrane and secondary colloid change. The ulcer was situated in the posterior wall near the cardia; its bottom being formed by scar tissue in the spleen and the peritoneal coat of the transverse colon. Communication with the abdominal cavity had been prevented by firm adhesions. The omentum contained a number of colloid granules as large as peas. The abdominal lymph glands appeared to be amyloid. The case was remarkable, first, in the complication of hypertrophy with gastric ulcer, a condition which the reporter had never before seen; second, in that the hypertrophy should commence at the cardia instead of at the pylorus.

DR. FORMAD also exhibited a specimen from a case of

Stab Wound of the Abdomen.

Laparotomy had been performed, and a wound of the intestine found, which was subdued. The man died suddenly sixty hours after the operation. At the autopsy there was only a very slight amount of peritonitis found, and the wound in the intestine had firmly united. The abdominal condition not being sufficient to account for death, the brain was examined, and a very distinct embolus in the floor of the fourth ventricle found. The stomach had not been touched, but on its peritoneal surface were some slight tears, and opposite them, in the mucous membrane, but not corresponding exactly with them, were several distinct, small linear ulcers, which appeared like ulcers due to some injury. They did not look at all like ordinary ulcers, but still had evidently formed ante-mortem. There was an old hemorrhagic impact of the kidney.

DR. OSLER had been particularly interested in the specimen, and had hoped that possibly it might prove to be related to the formation of gastric ulcer in the way pointed out by Dr. Baumgarten, and to which he wished to call attention, namely, that the movement of the stomach against the costal edges produces distinct localized thickenings, and that in corresponding points of the mucous membrane ulcers form.

DR. FORMAD also presented a specimen from a case of

Gunshot Wound of the Heart.

The ball had entered the chest between the fourth and fifth ribs on the left side, passed through the left ventricle, and was found imbedded in the spinal column. Death was instantaneous. The principal point of interest lay in the fact that the ball had traversed the cavity of the left ventricle near its base, without injuring the chordae tendinæ or the leaflets of the mitral valve.

DR. WESCOTT presented a

Mediastinal Tumor,

removed from a man aged 28, who had entered the University Hospital a week ago. He was a brakesman, with good family history and personal habits, and no venereal history. He had been in good health and at his work till last July, when dyspnœa developed, and he quit work. About the same time he noticed a tumor in his neck. There was no pain nor difficulty of swallowing. On admission he was in a condition of

orthopnœa. Over the left side of the chest there was complete dulness, extending to the right edge of the sternum, with absence of respiratory murmur. The apex beat of the heart could not be seen or felt. The tumor of the neck involved the superficial lymph glands, and could be traced behind the sterno-cleido-mastoid muscle, and down into the chest. There was no inequality of the pupils, and no œdema. At the autopsy, on opening the chest nothing but a large fleshy mass and the edge of the right lung could be seen. The mass penetrated the chest wall, between the first and second ribs, and became continuous with the tumor in the neck. It was closely attached to the bodies of the dorsal vertebræ from the first to the fourth, filled all the upper part of the left chest, and completely enveloped the great vessels. The œsophagus was pushed to one side, but not compressed. The left lung was completely collapsed, and contained numerous secondary nodules. The heart was pushed down and back, but was normal. The mesenteric glands were enlarged. A section of the tumor showed largely fibrous tissue. The reporter asked whether in the case of such a large mass the absence of pressure symptoms was not remarkable.

DR. J. B. WALKER said that in the absence of pressure symptoms such a large tumor was in his experience unique, generally very much smaller ones giving rise to marked symptoms.

W. E. HUGHES, M. D.,
Recorder.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Concealed Testicles, with Malignant Disease of One.

Dr. Jamieson reports the following case in the *China Med. Missionary Journal*, March, 1887: 'The following case is imperfect inasmuch as it lacks post-mortem confirmation of the diagnosis; but apart from the question of disease, the retention of both testicles in the abdomen is a condition sufficiently rare to merit record. Hunter saw only one case "in the human subject where both testicles "continued in the abdomen. . . . We "are led to conclude that they were perfectly formed, as the person had all the power and passions of a man" (*Works*, Ed. Palmer, iv. 17). Marshall (*Hints to Young Medical Officers in the Army*, p. 207), among nearly

11,000 recruits, also met with but one instance in which neither testicle had descended. In the *Transactions of the Maryland Medical and Chirurgical Faculty*, for 1884, there is an admirable table of 89 cases of retained testicle compiled by Dr. R. W. Johnson from the medical literature of the last three centuries. Unfortunately, there is no certain indication of the number of observations of complete cryptorchidism. In 8 cases no testicles could be found post-mortem; in 18 both testicles were in the inguinal canals; in 8, one was in the canal while the other was undiscoverable. Ten cases are specified as having had children, and one case of double retention was the offspring of a monorchid. "Some are found effeminate, others manly; some hairy, others beardless; some with other deformities, others deficient in this one respect."

Curling (*Diseases of the Testis*, pp. 334, 479) refers to the frequency of malignant degeneration of testicles retained in the groins. Those who are interested in the literature of the subject will find in the *Bulletins de la Société de Chirurgie de Paris* (Séance du 10 décembre 1879) a paper by Monod on 42 cases of inguinal castration for "sarcocèle" (sarcoma?). The same series, along with 8 other cases in which castration was performed for non-malignant affections of the retained gland, forms the subject of an extremely valuable and exhaustive paper by MM. Monod and Terrillon in the *Archives générales de Médecine*, 1880, i. 129, 297. This paper may now be regarded as classical. Its general conclusions are (1) that castration is advisable to relieve the severe suffering frequently arising from undetermined causes in undescended testicles; and (2) that where an undescended testicle is removed on account of cancerous degeneration, if the operation be not itself fatal, the disease inevitably recurs with rapidity.

It will readily be understood therefore that, while proposing castration in the case now to be related, I did not press the operation.

Ho, aged 51, native of China, first seen 16th July, 1886. Unmarried. Leads a very laborious life which involves much traveling, alternating with sitting in a constrained position for several hours at a time. Traveling by boat, barrow or sedan fatigues him considerably, but he is never sensible of absolute exhaustion except after his spells of sitting. Has always been subject to epistaxis and has frequently spat blood at the same time that his nose bled. His health has in general terms been delicate, but he continued reasonably well up to the end of April, 1886. At this date, without any a signifiable cause, the lower part of the abdomen began to swell and become hard, and retention of urine occasionally occurred. There were never any chills or fits of sweating, and he denies having ever suffered from malarial fever. The swelling has never been very sensitive to pressure: but it has given rise to uneasiness sufficient to interfere with sleep, and within the past fortnight, this uneasiness has developed into constant agonizing pain. Quantity of urine much diminished, and the act of micturition is performed at long intervals, 2½ hours or more. The urine leaves no deposit, but is dark, not blood-stained. There is a slight burning sensation in the urethra immediately after passing water. The stream sometimes stops suddenly as if a tap were turned. No pain in glans penis or down thighs. No history of intermittent lumbar

pain. No thirst. Complete anorexia. Has wasted much since appearance of symptoms, but is still a well built, fairly muscular man. Does not cough. Bowels habitually constipated.

The urine was acid, deep yellow, containing no blood or casts. Flocculent deposit of mucus with bladder epithelium. Had a peculiar earthy odor. Contained no sugar. No deposit with heat and nitric acid; slight deposit with citric acid and ferrocyanide of potassium. S. G. 1029. Average daily excretion 240 c.c.

The tongue was somewhat glazed; pulse, 84; regular, compressible; no hardening of arterial wall. Heart and lungs healthy, but respiration feeble, and slight dyspnoea induced by suddenly lying down. Slight upward increase of hepatic dulness, from displacement. From umbilicus to pubes the abdomen is occupied by an absolutely smooth, ovoid tumor upon which the muscles glide freely. It is hard, gives no sensation of fluctuation, is perfectly symmetrical, very slightly sensitive to pressure, almost fixed, but susceptible of restricted lateral movements. It curiously resembles a pregnant uterus of about the sixth month. On deep exploration a prolongation can be felt on the left, to the side of the pelvis just below the anterior inferior spine. Nothing corresponding to this prolongation can be found on the right side. The lower border corresponds to the posterior surface of the horizontal rami of the pubes. The tumor has displaced the intestines backwards. It is dull on percussion, though there is some conduction from tympanitic bowel in either lateral region of the abdomen.

The urethra easily admits a No. 22 (French) short beaked sound, which, however, cannot be manoeuvred in the bladder. Gentle exploratory movements are not painful, and, so far as can be judged by touch, the vesical mucous membrane is healthy. The point of the sound can be turned over slightly towards the left side of the bladder, but not at all to the right. No calculus was felt. Rectal examination negative; base of bladder and prostate normal. A few drops of blood-tinged urine followed the withdrawal of the sound, but there was no aggravation of any of the symptoms after the exploration.

While examining the rectum I noticed that the scrotum was represented by a mere roughening of the anterior portion of the perineum, and that there was no trace of testicles. Nor was anything resembling a testicle discoverable in the right inguinal region.

There was no scar on the undeveloped scrotum. The patient presents none of the characters of a eunuch. He has a good moustache, and there is as much hair as usual for a Chinaman on the pubes. The penis is well developed. His voice is not cracked; his skin emits no peculiar odor; he confesses to sensual feelings and has had occasional pollutions, but I have special reasons for knowing that he has always been absolutely chaste.

Those who have had much medical practice among the Chinese well know that a native has always some story ready, generally false, to account for every peculiarity observed during a physical examination of his person. I was not therefore surprised to learn that at the age of 6, in consequence of some combined internal and external treatment for a disease about which he could give no information except that it was of great severity, his testicles and scrotum dried up and disappeared.

He was ordered milk and Vichy water, and 1 gramme of chloral hydrate every four hours. Sleep and appetite returned for a few days, but as he soon tired of the milk diet, and the chloral speedily lost its effect, the patient abandoned all faith in foreign treatment and placed himself in the hands of a succession of native practitioners. Each guaranteed cure, and administered quantities of medicine, dieting him carefully, but in the most fantastic fashion. One of his attendants, for example, made him live for ten days exclusively on ducks. I received news of him from time to time, but never saw him after his repudiation of foreign treatment. His medication appears to have been mainly sedative, in spite of which he suffered horribly and was almost sleepless. There was comparatively little change until the beginning of December, when the tumor suddenly began to enlarge with great rapidity, so that within three weeks it occupied the entire abdomen and encroached largely on the thorax. At the same time there was a notable diminution of pain, but dyspnoea became urgent and sleep impossible. The patient died exhausted on the 28th December. No post-mortem was allowed.

The Prophylactic Advantages of the Early and Continued Inunction of Carbolic Oil in Scarlet Fever.

Dr. John Brown, Medical Officer of Health of the Borough of Bacup, writes as follows: Scarlet fever and small-pox are the two diseases, *par excellence*, in which early isolation, as a rule, effectually stamps out the

disease. Isolation, however, is not adequately provided for by the sanitary authorities. Even where hospitals are provided there exists a great prejudice against them, and they are rarely made use of, unless compulsory measures are enforced. Isolation in the home is rarely possible among the working classes, therefore any treatment which can be carried out in the home which promises to prevent the spread of scarlet fever must be a great boon. Experience has proved that scarlet fever generally attacks every inmate in the home who is susceptible to the contagium, or who has not been protected by a previous attack. The contagium is spread chiefly by the peeling of the epidermis. Any treatment which can destroy the germs and prevent the dissemination of the skin, must prove a valuable prophylactic. The treatment which I have carried out for a period of nine months partially, if not effectually, fulfils these two things. The success has been very satisfactory, although the treatment has not been rigidly carried out in all its details; this applies particularly to the operative class, who have not the time to do all that they would. *Treatment.*—As soon as the rash is out, apply carbolic oil all over the body, except the face, over which apply olive oil. Let this be done twice a day, with a warm bath every night. Continue this treatment until the fourth to the sixth week, when we may hopefully expect to have prevented the spread of the disease. The carbolic oil contains 5 per cent. of carbolic acid. It is important to have the pure medicinal carbolic acid and the best olive oil. The patient should not be exposed during the process; the temperature of the room should be 65°; the hand must be warm. In a severe epidemic of scarlet fever, the Town Council adopted my recommendation, and provided carbolic oil for free distribution. In twenty-five consecutive cases taken from my note-book, there was not one death, no case of renal dropsy, nor any sequelæ of any importance. There were five cases between 1 and 5 years, fifteen between 6 and 12 years, and one adult. The *rationale* of the treatment may be summed up as follows: Carbolic acid is an antiparasitic, and probably destroys the vitality of the germs; it also acts as a sedative to the skin by its anæsthetic action on the sensory nerves, and thus conduces to the comfort of the patient. Pure olive oil arrests the dissemination of the skin, which is removed by the daily warm bath. It probably assists in the earlier desquamation of the skin, and also prevents the susceptibility to chill during the convales-

cent stage by forming a thin covering for the skin, and thus warding off the tendency to renal dropsy; it conduces to sleep by allaying the irritable itching of the skin, and gives a sense of coolness which many patients highly appreciate, especially in the early period. The oil prevents the free access of air to the skin, and may thus attenuate the virulence of the contagium. If properly carried out there are no dangers in the treatment. In no case has it produced any unpleasant symptoms. The carbolic acid has not been absorbed so as to affect the urine. Last December I was informed that Dr. Taylor, of London, wrote a little book over twenty years ago, in which he advocated the injunction of suet and lard in the acute stage of scarlet fever. Not having seen the pamphlet, I am unacquainted with its details.—*Brit. Med. Journ.*, Aug. 13, 1887.

Ligature of the Common Carotid in a Case of Scarlatina Complicated with Diphtheria—Recovery.

Selenkow reports in the *St. Petersburg mediz. Wochenschrift* the case of a girl nine years old, who was taken sick with a severe attack of scarlet fever, and three days afterwards with anginal diphtheria. On the sixth day, marked swelling of the cervical lymph glands occurred. On the eighth day an incision was made into the swelling, which fluctuated superficially, and drainage given. Three days afterwards, profuse arterial hemorrhage occurred, which was finally controlled by compresses upon the carotid. Pronounced anæmia and collapse resulted. The common carotid was tied in the cavity of the abscess at the level of the second ring of the trachea, and the cavity itself emptied, and then packed with tampons. Five days subsequently there occurred delirium, twitchings of the muscles of the face and body on the left side, and dysphagia and paresis of the whole left side of the body. Six months afterwards the following symptoms continued: Paresis of the extensors of the left hand (radial nerve), and of the peronei (peroneal nerve) of the left lower limb; slight dilatation of the left ventricle; symptoms of deficient nutrition of the cerebral cortex.

Cases similar to the above are rare. Selenkow discusses the question whether the paralysis depended upon the tying of the artery or upon the diphtheria. Against its dependence upon the ligature he places (1) the late period of its occurrence—five days after the operation; (2) the gradual passage of paresis into paralysis; (3) its too long

duration. Against its dependence upon diphtheria, are (1) absence of any paralysis of the throat muscles; (2) the long duration of complete paralysis of the lower extremities; (3) its marked unilateral appearance. The author, in conclusion, says:

Hemiplegia and disturbances of speech result from degenerative processes of the great cerebral ganglia as a consequence of one-sided ischæmia in general oligæmia. The paralysis of the radial and peroneal that remained is of a diphtheritic nature. The incipient delirium is certainly not to be referred to intoxication with iodoform, but was the result of œdema of the brain upon the ligated side.—*Deutsche Medicinal-Zeitung*, September, 1887.

The Dangers of Antipyrin Given in Pregnancy.

O. Cléron (*Journal de Médecine de Paris*, No. 5, 1887) states that he gave antipyrin, in doses of fifteen grains at intervals of five hours, to a woman who was eight months pregnant, and was suffering from typhoid fever. After this woman had taken thirty grains, her temperature fell from 108.5° F. to 95.9°. Convulsions immediately occurred, with impeded speech, deafness, and finally loss of consciousness. After much labor this condition was overcome by the use of the strongest stimulants. In another case a similar condition was brought about after giving six grains of antipyrin at intervals of three hours.—*Allgemeine med. Central-Zeitung*, August 27, 1887.

Differential Diagnosis of the Tuberculous Meningitis of Childhood.

Simon says (*La Semaine Médicale*) that the difference of symptoms in cases of tuberculous meningitis is partly dependent upon the greater or less extent of inflammation, upon the locality of the latter, and upon the occurrence of accidental affections, such as dropsy of the cerebral ventricles. He distinguishes three forms, the creeping, the intermittent and the typhoid. The course of the disease is influenced by complications with tuberculosis of the lungs, peritoneum and bones, and by the age of the child; the disease pursuing a more rapid course in a child over ten than in one under ten years of age. As to the differential diagnosis, much difficulty is encountered in distinguishing between tuberculous meningitis and typhoid fever, and, a very important point, between the former and pneumonia; for the latter disease is characterized by a

very sudden beginning and an immediate high rise of temperature.

Most cases of so-called cured meningitis, Simon regards as mistakes in diagnosis for cerebral congestions complicated with acute hydrocephalus—an affection undescribed, but undoubtedly existing; occurring especially as the result of catching cold, and after eruptive fevers, indigestions, gastric disturbances, and even after simple sore throat. This affection at the beginning is deceptively like tuberculous meningitis. Moreover, severe intermittent fever may likewise simulate meningitis; but here the action of quinine renders the diagnosis certain. Cerebral sclerosis, before the stage of paralysis, is also apt to become confused with meningitis.

Violent long continuing headache is also found in rapidly growing children between four and seven years of age, especially if overworked in school; but a suitable dietetic regimen will soon cause these headaches to disappear, and will prevent errors in diagnosis. Children of parents who have migraine, gout or rheumatism, frequently suffer from persistent headache, which finally appears as an otitis, and as hysteria, though not to such a degree that an error in diagnosis cannot be avoided by the exercise of some care.—*Deutsche Medizinisch-Zeitung*, September 1, 1887.

Milk Supply and Scarlet Fever.

An important relationship between the milk supply of large towns and the dissemination of scarlet fever was established by Dr. Anderson, medical officer of health, Dundee, at a meeting of the Dundee Police Commission held last week. He read a letter, which he had sent to the clerk of the local authority, stating that an outbreak of scarlet fever took place recently at a dairy farm close to Dundee, and from which milk was sent into the town. The sanitary inspector for the district (the parish of Tealing) was informed, and he suggested some trifling attentions to be given in the storage of the milk, but the scarlet fever patient was not removed, and the milk continued to be delivered in Dundee. The medical officer of health thought it a great hardship that the public health of Dundee should suffer from the gross laxity with which rural local authorities enforced the regulations for the protection of milk. He further added that the attention of these authorities should be specially drawn to this matter. Scarlet fever prevails very extensively in Dundee at pre-

sent, and this was not to be wondered at when such a state of matters existed. Recently he discovered that for three weeks the milk of forty cows had been coming into Dundee twice daily from a farm in which fever existed, and he reminded the Commission that, as more than half of the milk supply came from places outside the burgh, it is necessary that very particular precautions should be taken, and that the local authorities should be informed and asked to enforce the powers which they possessed. He contended that there should be a more careful and vigilant inspection of milk in country districts, and he held that it ought to be distinctly known by all engaged in the milk trade that for the future the excuse of ignorance would not be sufficient. It was the duty of every one to know the rules applying to his or her particular trade, and he desired to warn all milk dealers that if there were any more cases of gross negligence or carelessness they would be dealt with in an exemplary manner. The meeting agreed to send copies of Dr. Anderson's letter to the Board of Supervision, and to the local authority for the parish of Tealing.—*Brit. Med. Journal*, August 27, 1887.

BOOK REVIEWS.

Manual of Clinical Diagnosis. By Dr. Otto Seifert, Privat-Docent in Würzburg, and Dr. Fredrick Müller, Assistent der II Med. Klinik in Berlin. New edition revised and corrected by Dr. Fredrick Müller. Translated, with permission of the author, by William Buckingham Canfield, A.M., M.D. (Berlin), etc. With sixty illustrations. 8vo, pp. xii, 173. New York and London: G. P. Putnam's Sons, 1887.

Nothing is pleasanter to the critic, notwithstanding the unenviable reputation which he is apt to bear, than to be able to praise a book warmly and sincerely. This pleasure the book now under consideration affords us. It discusses, in a clear, orderly and exhaustive manner, the various phases of clinical diagnosis under the following headings: The Blood in Health and Disease; the Temperature; the Organs of Respiration; the Circulatory System; the Digestive and Abdominal Organs; the Urinary Apparatus; Transudation and Exudation; Parasites—Animal and Vegetable; the Nervous System; Pathological Conditions; and Metabolism and Nutrition. The last heading includes a study of foods,

and the book concludes with a very full table of remedies.

Our space will not admit of any detailed analysis of this admirable work, which might well find a place in the hands of every student or practitioner of medicine. We are happy to be able to say that the publishers have done their part in its preparation as well as the author and translator have done theirs, and to praise the excellence of the illustrations which accompany the text.

One criticism only we would make: That the translator might improve his work a little. He adheres somewhat too closely to the phraseology of the original language, sometimes even mistranslates. "Dornapfel" crystals might be better described as "chestnut-burr" crystals than as "thorn apple," which is a somewhat unfamiliar name for the pod of the Jamestown weed. The "Titrimethode" is the *titration* method; not "trituration." With this exception, we have nothing but praise for the book before us.

Prophylaxie publique de la Syphilis (Public prophylaxis of Syphilis).

By Alfred Fournier, Clinical Professor of Diseases of the Skin and of Syphilis, in the Faculty of Medicine of Paris, etc. 8vo, pp. 64. (Paper.) Paris: J. B. Baillière et Fils, 1887.

The occasion for this monograph is stated in its first paragraph: "In the course of the discussion which has taken place here (the Académie de Médecine) in regard to the present depopulation of France, the Academy, justly affected by the frightful mortality among children with hereditary syphilis, and by the notorious insufficiency of administrative measures which are intended to protect us against syphilis, named a Commission to study what reforms or changes should be inaugurated in the public prophylaxis of this disease, and to prepare the plan of a Report on this subject which might be addressed to the proper authorities."

Fournier drew up this report to the Academy, and his monograph contains it. Fortunately for our country, syphilis is not here such a scourge as it is in France, and we can hardly realize the gravity of the problems it presents to the inhabitants of that country. Equally, we have no need of the stringent measures which seem to be demanded there; and the Report of Fournier and his able collaborators has little more than a literary interest for us. This, however, it has; and it can be commended to the careful and thoughtful study of syphilographers here, or all over the world.

Romantic Love and Personal Beauty.

By Henry T. Finck. 8vo, pp. xii, 560. London: Macmillan & Co., 1887. Received from the J. B. Lippincott & Co., Philadelphia. Price, \$2.00.

Mr. Finck has for a long time been engaged in collecting material for this curious volume, in which he discusses in the most unimpassioned manner the nature and characteristics of what he calls romantic love—that is the love of lovers, as distinguished from conjugal affection. The former he believes is a development of comparatively modern times, and that it is not—as is usually supposed—as old as the history of mankind. It would be impossible, in the space at our disposal, to give an idea of the curious and entertaining character of this book; but we can strongly recommend it to our readers as a perfect encyclopædia of the subject of which it treats.

Biography of Andrew Nebinger, M.D.

By J. H. Grove, M.D. 8vo., pp. 15. A biographical sketch read before the Philadelphia County Medical Society, May 11, 1887.

We call attention to this brief pamphlet on account of the fact that it is an interesting tribute to the memory of a man who was a typical physician—a man of strong opinions, of kind heart, of good judgment, a good friend, and a steady defender of what he believed to be right. He was a fair specimen of the medical men who, in thousands of cities and towns and rural communities, become worthy leaders of public opinions, and tender helpers to the distressed of every sort and condition. May the number of them increase!

LITERARY NOTES.

—We have received the eighth volume of the Index Catalogue of the Library of the Surgeon-General's Office, U. S. Army. It is a continuation of a work whose merit is above praise. The present volume extends from "Ledger" to "Medicine (Naval)." References to Lithotomy cover 31 pages; to the liver, 71 pages; lungs, 42 pages.

—*The International Medical and Surgical Synopsis* is the title of a monthly journal of which the first number was published at St. Louis in September, 1887, by an association of the same name.

—The November *Harper's* will contain an important article for health-seekers, under the title of "The Winter Climate Resorts of Three Continents," by William Smith Brown. Mr. Brown has for forty years made the matter a special study in his wide travels, and masses into nine pages the net result of his researches regarding the invalid resorts of Egypt, France, Italy, Algiers, Spain, Switzerland, and the United States.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D., } EDITORS.
CHARLES W. DULLES, M. D., }

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should always state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

EXPERIENCE OF COUNTRY PRACTITIONERS.

In a recent article one of our cotemporaries incidentally pays a high compliment to the opinion of country practitioners. A large proportion of them, it says, are close observers, who make their own experience, and who know well what they can do with the comparatively few agents they employ. For this reason he attaches much weight to their choice of drugs, and thinks that what they habitually use must be useful. In this sentiment we heartily concur. We know well the value of the opinion of the men who use the opportunities afforded by large cities to increase their own knowledge and that of their fellow-practitioners. But we also appreciate the opinions of those who, amid the hardships and difficulties of country practice, gather facts day by day, which make their judgments clear and their acts wise. These hard-working and ill-paid men are often little known to fame, outside of the region of

country in which they dispense their good deeds; but they are in every sense the peers of those who have a more brilliant lot. It is a misfortune that so much of what they know cannot be communicated to their fellows through the medium of the medical journals. This is partly due to their modesty and partly to the fact that they rarely find time to put their experience into writing.

For innate modesty we cannot suggest a cure; for lack of time, we can—Be brief! An experienced editor recently remarked that no article is so good that it would not be better if it were shorter. This is true, and we can assure any of our readers who would like to publish an observation or experience, which they think might prove useful to others, that they need not wait until they can write an article. It will be much better perhaps to put what they would say in a short letter, and send it to the journal they read. In the case of our readers, we would like to say that we would be very glad to have short, crisp letters, occupying, say, one or two pages of note-paper, giving accounts of rare or instructive observations, or suggesting methods of treatment, to be published under the head of "Correspondence." We do not mean to curtail any other department of the REPORTER; but we will make room for any letters of the sort just described, and have no doubt they will make this journal more interesting and more popular. But—make them short!

SHALL A DOCTOR INFORM ON A CRIMINAL?

A circular has recently been issued by Pinkerton's National Detective Agency asking each physician who receives a copy to give information to the Agency in case a suspicious person should come to him for treatment of a gunshot wound of the jaw. It seems that on the morning of Friday, September 30, 1887, burglars entered the residence of the Cashier of the Farmer's Bank of New Castle, Del., where the bank is also located, and attempted to overpower the Cashier and his family. A fight ensued, and the Cashier shot and wounded one of the burglars. The ball is supposed to have entered the mouth of the burglar, shattering the jaw-bone and

carrying away with it a portion of the bone—a piece of which has been found in the blood which came from the wound, and experts pronounce it a part of the jaw-bone.

The Detective Agency wishes the coöperation of medical men in securing the apprehension of this criminal, and we hope may have it.

As a rule, physicians should religiously guard the secrets of their patients, and especially when to reveal them would expose the patients to shame or punishment. But this rule cannot be strained so as to apply to the case of a murderous fugitive from justice. A man who breaks into the house of a keeper of other people's moneys and makes an attempt upon his life in order to complete a felony, is an outlaw, and whatever pity any man or any physician might feel towards him should be counteracted by the pity he feels for every law-abiding citizen. When the consequences of his crime bring a dangerous criminal to the notice of a medicalman, we hold it to be a duty to the State that the latter should disclose the fact; to the proper authorities, and not hold back from any false notions in regard to professional confidences.

VENTILATION.

An item is going the rounds of the daily papers which states that Prof. Virchow says, concerning the keeping windows open in sleeping apartments: "The vitiated air can only rush out when the temperature inside differs from that outside; it remains stationary when the air inside is already of equal temperature with that outside. In that case serious complications may be the consequence, and many persons have paid for their mistaken notion with their life."

This is a fair illustration of the sort of teaching which sometimes gets abroad, and which is accepted because it is attributed to a deservedly respected source. We trust that Virchow did not say what we have quoted; if he did, it ought not to pass unchallenged. Many Europeans have a morbid dread of fresh air, especially at night. Many of their houses are provided with double windows, which

effectually exclude the outer air at almost all times. This may not seriously affect the health of Europeans, and they may be justified in following their inclinations in regard to the ventilation of their sleeping apartments. Virchow himself has, we believe, done a good thing in showing that the danger from draughts of air is sometimes greater than the supposed danger from an atmosphere supposed to be vitiated. But he would be the first to recognize the fact that there could be no danger from draughts under the conditions mentioned in the warning he is credited with, as stated above; and that if there was no way in which opening a window could bring about a change in the inside atmosphere, there would be no way in which it could bring danger—except from thieves. But the comment we have cited overlooks the fact that a change of air can be effected without any "rush" or difference of temperature, by the gentle movements which the atmosphere usually experiences, and that these movements probably contribute more to ventilation than the mere states of warmth or coolness. In fact, what Virchow is said to regard as the condition of greatest danger is really the safest. The best time to open windows is when the air is still, and when there is no great difference between the temperature inside and outside of a house. There may be times and places when and where it is undesirable to admit the external air to a bed-chamber; but they are very few—far fewer than most people suppose. We do not advocate a very low temperature in bedrooms, or consider it wise to sleep in a room exposed to draughts or to the cold of a winter night. But we are glad to believe that Americans, as a class, are not afraid to properly ventilate their sleeping apartments, and we hope they will not be frightened by the citations of even so eminent an authority against the practice.

VERATRUM VIRIDE.

In the issue of the *Ephemeris* for October, 1887, Dr. Edward R. Squibb publishes a "Note on Veratrum Viride," which con-

tains an interesting statement of the character and uses of this drug. He notes the fact that it is more used by country practitioners than by those living in the cities, and thinks this indicates its value, as country practitioners would not continue to use it unless they saw that it produced good results; and he does not hesitate to set their experience against the theoretical objections of certain authors. He considers it a potent and fairly manageable arterial sedative—better than aconite, in that it reduces the force and rapidity of the heart's action more powerfully and more promptly. Norwood's tincture, which has so extensive a reputation, he says, is only half the strength of the official fluid extract. As to the use of *veratrum viride*, he advises choosing the fluid extract and administering two minims every three hours, in a little water, and increasing to three minims at the third dose, if no effect is perceptible at that time. This is the treatment for ordinary cases. When a rapid effect is desired, from four to six minims may be given every hour or two, until the pulse-rate falls to fifty or sixty beats per minute, when the dose must be lessened and the intervals lengthened, so as to keep the pulse just as it is wished. Owing to the uncertainty of its absorption from the stomach, either the fluid extract or the tincture of *veratrum viride* may be given hypodermically. In grave cases, from eight to ten minims of the fluid extract, or double this dose of the tincture, may be given every fifteen minutes at first, and then every half hour until the pulse-rate falls to sixty beats per minute; after which the smallest dose which will keep it there must be used.

These views of Dr. Squibb coincide, we believe, with the opinions of those who have employed *veratrum viride* most frequently in their practice. It is undoubtedly a drug of great value when judiciously employed. It is true that it will not always succeed, and that its administration is not free from danger; but it is a drug which will render good service if used without timidity, and we are sure that many of our readers could testify to its usefulness when given courageously—not rashly.

NOTES AND COMMENTS.

The Value of the Modern Method of Treating Syphilis by Hypodermic Injections.

Dr. Prince A. Morrow, in a communication under this heading to the *Medical Record*, October 15, 1887, says: A careful weighing of this clinical testimony, balanced by my own observation and experience, justifies the following conclusions:

The hypodermic use of mercury, in simplicity, convenience, scientific accuracy, rapidity of action and the development of a maximum effect from a minimum quantity, constitutes a decided improvement over the ordinary modes of introducing this drug into the system.

The hypodermic method is not so liable to cause salivation, gastro-intestinal disorders and other toxic symptoms of hydrargyrisms.

There is remarkable unanimity of opinion as to its efficacy in suppressing the active manifestations of the secondary stage, and hastening their involution.

The claim that the hypodermic use of mercury increases its potentiality and widens the range of its curative action, enabling it not only to subdue refractory secondary lesions which resist ordinary treatment, but also the tertiary lesions of syphilis, may be considered as yet *sub judice*.

The claim that it endows mercury with a greater permanence of action, preventing relapses and preserving the patient from manifestations of the diathesis for a long period, is not proven.

The more pretentious claim that the hypodermic injection of twenty-five centigrammes of the bichloride, or forty centigrammes of calomel, cures syphilis, must be rejected as extravagant and absurd.

The irritant action of mercury introduced subcutaneously, manifest in the production of pain and local accidents, renders its general employment in the systematic treatment of syphilis impracticable.

Until these objectionable features be modified or overcome, the proper position of hypodermic medication in the therapeutics of syphilis is in the category of adjuvants.

Its employment is indicated where the necessities of the case demand a rapid and intense mercurialization. In certain emergencies, when, for example, the integrity of an important organ is threatened, its prompt and energetic action renders it superior to other modes of mercurialization.

In exceptional cases, marital syphilis, for example, where the exigencies of the situation demand secrecy in treatment with the speediest possible suppression of the symptoms, this method is to be recommended.

In cases where gastro-intestinal irritation is so marked as to forbid the introduction of mercury into the stomach, it constitutes a most efficient reserve treatment.

In tertiary syphilis, where the iodine idiosyncrasy is so marked as to preclude the use of iodide of potassium, the hypodermic use of mercury should be substituted.

My own impression is, that while the hypodermic method will never supplant the classic modes of employing mercury, yet it constitutes a decided acquisition to our therapeutical resources against syphilis, too valuable to be ignored or practically disregarded, as has been the case in this country.

The actual worth of mercury administered hypodermically can only be determined by cumulative experience. Dr. Morrow's paper is a timely one, and his conclusions as stated seem just and in the main correct.

Report on Progress in Therapeutics.

From a paper by Francis H. Williams, M.D., on this subject, contained in the *Boston M. and S. Journal*, October, 13, 1887, we abstract the following:

Naphthalin.—Naphthalin seems to be of special value as an intestinal antiseptic or germicide—being so sparingly soluble that much of it remains to act upon the intestines and their contents from the stomach to the rectum. Its value is especially urged by Dr. L. Emmet Holt, who concludes that summer diarrhoea has many remote causes, but the single immediate cause is putrefactive changes taking place in undigested food in the stomach and bowels, the products of these changes acting either as systemic poisons or locally irritating agents, causing catarrhal and inflammatory conditions in the intestines. The diarrhoea is, at the outset at least, salutary, and the use of astringents and opium is not only useless, but, in the beginning especially, may do positive harm by checking peristalsis and increasing decomposition.

The indications to be fulfilled are: (1) Clear the bowels; (2) stop decomposition; (3) restore healthy action; (4) treat consequential lesions. To meet the first he recommends castor oil; the second, salicylate of sodium or naphthalin; the third and fourth, if present, call for various measures, but in the majority of cases castor oil and salicylate of sodium or naphthalin were alone neces-

sary. He also reports seven cases of chronic dysentery and twenty-one cases of chronic diarrhoea, treated by naphthalin *alone*, with uniformly good results. Concerning the dose and administration: it may be given in powder, mixed with sugar and taken in wafers or capsules; the taste is not bad, but very persistent and strongly suggestive of tar.

In summer diarrhoea of children, he used from two to six grains, according to the age. In chronic diarrhoea, dysentery and typhoid, he used large doses of naphthalin, sixty to ninety grains daily.

Though Prof. Bouchard has reported that animals to whom naphthalin was administered internally developed beginning cataract within twenty days or less, generally in both eyes simultaneously, and that the cataract process thus begun did not stop with discontinuence of the drug, the doses used were, for the animal, excessive, and very likely have no important bearing against the therapeutic use of the drug. Certainly no untoward effects are reported from its clinical use, except dark-colored urine and a single case of dysuria from large doses.

Resorcin.—This drug is favorably reported in the treatment of cutaneous and gastric disorders. Dr. Maclay reports two cases of gastric ulcer with immediate recovery under its use. In gastric catarrh not relieved by bismuth, soda, etc., recovery followed at once under treatment with resorcin. Intestinal catarrhs, chronic diarrhoea, etc., were in no way benefited by resorcin, nor were the evacuations disinfected, constituting a marked contrast to the action of naphthalin, and suggesting a special field of action for each of these two drugs; naphthalin for intestinal disorders or wherever it is desirable to disinfect the intestinal canal or render antiseptic its contents; resorcin for the same purpose in the stomach and externally on sensitive tissues. Internally, Dr. Maclay employs five grain doses of resorcin three times a day, given in water with a little glycerine, or in chloroform water. The taste is peculiar, but slight, and easily tolerated. Much larger doses have been employed, but are not advisable, thirty grains having caused febrile disturbance, and sixty grains marked toxic action, dizziness and collapse.

Corrosive sublimate.—The use of corrosive sublimate as an antiseptic has been on the accepted ground that in the weak solutions employed, while destructive to germs, it is not dangerous to the patient. Some recent observations and cases would suggest considerable caution, at least, in its use. Fleischmann, of Prague, reports a fatal case

of acute poisoning in a healthy primipara, from two vaginal douches before labor, sublimate solution 1 : 2000 being used.

Fleischmann calls attention to the danger attending the use of sublimate in puerperal patients with any lesion or disordered conditions of the bowels or kidneys, and quotes an eminent authority to the effect that the use of sublimate in obstetrics should be limited to disinfection of the hands, instruments and external genitalia. An article by the Paris correspondent of the *British Medical Journal*, October 9, 1886, is of interest in this connection. He calls attention to the frequency of intestinal lesions coming to the notice of medical men, especially those in obstetric practice, since the wide use of corrosive sublimate as an antiseptic, and refers to the experiments of Prévost, indicating that visceral lesions may be produced by sublimate.

Maximilian Jolles and Erlangen give an elaborate demonstration of the identity of lesions and clinical history in sublimate poisoning and septic infection. Gläser, of Hamburg, reports twenty-three cases of typhoid treated with corrosive sublimate with very bad results and no benefits. In diphtheria, on the other hand, Dr. Verner reports seventeen cases with very good results, giving one-fourth to three-fourth grains daily.

The conclusions warranted, seem to be that corrosive sublimate is an efficient antiseptic, but best adapted to external use, suggesting caution in its use in obstetrics for douching, especially with any disorder of bowels or kidneys, and throwing doubt on the possibility of safe disinfection of the blood or intestinal canal by internal administration in infective diseases.

Urethan.—This is a generic name given to a class of ethers derived from carbonic acid, the name signifying the close chemical relation of this class of *ethers* to *urca*. "Urethan," however, has recently been employed to designate one of this class of ethers: carbonate of ethyl, or, strictly speaking, "ethyl-urethan." Ethyl-urethan, or urethan, as it is ordinarily called, is a white crystalline substance, very soluble in water, alcohol and ether at all temperatures.

Without going into detail concerning the very numerous reports of its action and clinical use, the following points may be considered as fairly well established. It is a hypnotic, acting chiefly by depression of cerebral centres, not sufficiently powerful to cause sleep if pain, persistent cough, great dyspnoea, or analogous conditions are present. It is of no value in delirium tremens.

In simple insomnia, nervous sleeplessness from worry, over-excitement, etc., and in many forms of sleeplessness in insanity, it is very uniformly effective, producing restful, dreamless sleep, closely simulating physiological sleep. It is slightly stimulating to the respiration, and does not depress the heart, even in toxic doses. This is a marked advantage in action over chloral. It has in ordinary doses no unpleasant after-effect, but very large doses produce gastric irritation with nausea and vomiting. Concerning the dose: twenty grains seems a medium dose. Buchard gave forty five to sixty grains, and considered a single large dose better than several small doses. German observers recommend doses of fifteen to thirty grains (some seven and one-half to fifteen grains). Ordinarily, a single dose of fifteen to thirty grains at bedtime gives sleep without after-effects. The drug is not disagreeable in taste, and, as noted, very soluble. Prof. Anress has demonstrated the antagonistic action of urethan to convulsive agents like strychnine and picrotoxin. He considers it a safer and more effective antidote to strychnine than chloral. Its therapeutic action, if correctly observed, is certainly opposed to such a view, as it is said to act chiefly on the *brain*, while strychnine convulsions are from the *cord*.

Nursing Infants with Asses' Milk.

Dr. H. G. McGrew, in a letter from Paris to the *American Lancet*, October, 1887, says: During the past few years one of the causes of the depopulation of France has been proved to be defective nursing and alimentation during infancy.

The medical authorities and Dr. Peyron, Director of Public Assistance of Paris, have exerted themselves to modify the system of nutrition in hospitals and other medical institutions by nursing the new-born according to the necessities of their constitution and temperament. At the Hospital for Sick Children, in the Rue de Sèvres, are a number of pale, sickly, miserable infants of both sexes, whose appearance is painful to see. These unhappy children are suffering from various diseases inherited from their parents. In order to avoid all danger of contagion, these cases are put into pavilions isolated from the main building. These wards are very comfortably arranged, each one being lighted with large windows looking out upon a garden, and containing a double row of neat, tidy cradles. Here the new-born receive all possible care and attention.

The moment a new boarder arrives, a nurse takes the infant and places it in a pair of scales, such as are used by butchers for weighing large pieces of meat. The weight is then registered. This operation of weighing is repeated from time to time in order to note the development of the child. The infant is then put upon a special regimen of the most strengthening character. It was customary to suckle the child suffering from hereditary disease with the udder of the goat, but notwithstanding the nutritive qualities of this milk, it was found that the neuroses, with which the goat is often afflicted itself, were communicated to the child, and so an animal had to be found which would produce a milk having all the properties of goat's milk, without its inconveniences. Consequently the ass was chosen, and a stable, with a capacity for a dozen asses, was built adjoining these wards, with simply a small passage-way between. There is nothing so picturesque as this display of babies in long dresses being placed to the udder of the ass, which they suck greedily. Each nurse arrives with her little stool, which she places on the litter beside the animal, which stands quietly while the little patient swallows large mouthfuls of creamy milk.

It is calculated that these asses can nourish habitually during a period of eight to ten months, after which they are sold and replaced by others. The asses' milk approaches nearest, as regards its nutritive properties, to the human milk, and under its employment these little patients thrive and gain from day to day strength and health.

Modern Diet and its Effects on Health.

Dr. M. A. Boyd, physician to the Mater Misericordiæ Hospital, Dublin, says there are some points in connection with this subject which are not of merely professional interest, but of far wider significance, and may be regarded as of national importance also, as they embrace not only our every-day condition of health as individuals, but our very physical existence as a race. Foremost amongst these points, the question how many of our modern diseases depend upon our diet, and why dyspepsia and its concomitant troubles are so prevalent. In the consideration of this subject we might reasonably ask how much man's habits and occupation have contributed to the deterioration of his nervous and digestive powers? Where such a preponderance of albuminoids entered into our food as was at present the

case, the additional use of alcohol with them becomes a necessity, to aid in their digestion, more especially as from the impaired nervous energy of the present day the digestive organs require the stimulus they give to increase secretion. But is assimilation of a large quantity of albuminoids of benefit to our systems at large? Having regard to the fact that the ptomaines of our food were mainly derived from albuminoids, most certainly it cannot be; and in this meat-eating country, where, from climatic influences, rheumatism and its congeners are endemic, a greater liability to cardiac affections necessarily ensues. As most of the albuminoid waste passes through the kidneys, have we not a direct connection between our food and the prevalence of Bright's disease? The prevailing taste includes a large amount of animal food, and the present state of the laws allows too great facilities for all sections of society to poison themselves with this form of food. The State regulates the sale and the quality of the alcohol the public consumes, but exercises no control over the quality or character of the meat its people use. Some check must be put on the importation of meat, if the State desires a healthy population. This might seem an interference with the rights of trade; but it was very doubtful if the opportunity to purchase meat cheaply and use it in abundance was an advantage, looking at the matter from a public health point of view. It might be said that it was not the abundant use of meat, but the manner of cooking it, that was injurious. Granted that this was so, had not the State a greater reason to attend to the wants of its people in this respect? Schools of cooking, founded by the State, would seem, then, of paramount importance, to enable the poor to receive that instruction which was so essential to their moral and physical welfare.—*Brit. Med. Journal*, September 24, 1887.

Operations Upon the Kidney.

Dr. E. O. Otis, in an article in the *Boston M. and S. Journal*, says:

Two cases occurring in my own practice, the one fatal, and the other full of suffering, have indelibly impressed upon my mind the importance of surgical interference in certain affections of the kidney, notably calculus and suppurative lesions, as affording the only deliverance in otherwise hopeless cases. The one case was that of a young married man, who, for years, suffered from symptoms of renal calculus, enduring the most excruciat-

ing and convulsive pain of renal colic, and for which he vacillated between opium-eating and rum-drinking, becoming a curse to himself and his unhappy family. The other case was also that of a young man just beginning a professional career, from which he had much to hope, afflicted with a suppurative affection of one kidney. After dragging out a wretched existence for two years, he died of pyæmia, and the autopsy revealed an enormously dilated, pus-secreting sac in the place of the kidney. Both of these lives, I believe, might have been restored to usefulness and comparative health through the intervention of surgery.

To Simon, of Heidelberg, and Morris, of London, the surgical profession is indebted for firmly establishing the operations of nephro-lithotomy and nephrectomy, nephro-lithotomy having been first performed by the latter in 1880, and nephrectomy by the former in 1869.

Besides these two operations, with which the remainder of this paper will be chiefly concerned, we have nephrotomy, nephrorraphy, paracentesis, and what Mr. Lucas makes a distinct operation; exploration of the kidney, which is but a part of nephro-lithotomy.

Within the last few years, recorded cases of operations upon the kidney have been rapidly multiplying, and the literature upon the subject is becoming voluminous. Gross's paper, based upon an analysis of nearly four hundred and fifty cases of all kinds, embracing all he could collect up to May 15, 1885, is well known to you.

I have collected, of cases recorded since that date, sixty-eight operations of all kinds, as follows:

Nephrectomies, 28 with 6 deaths, 21.42 per cent. Of these 18 were lumbar with 2 deaths, 11.11 per cent.; and 8 abdominal, with 4 deaths, 50 per cent.; the incision in two cases was unknown. Nephrotomies, 13 with 4 deaths, 30.77 per cent. Nephro-lithotomies, 21 with 2 deaths, 9.52 per cent. Exploration, 2 with no deaths. Nephrorraphy, 4 with no deaths.

Drink for the Harvest Field.

R Sugar.....	½ lb
Barley meal.....	4 oz
Citric acid.....	½ oz
Essence of lemon.....	20 drops
Boiling water.....	1 quart

Mix and strain, then add cold water to make a gallon.

—*Chemist and Druggist*, Aug. 27, 1887.

Poisoned by Three Drops of Laudanum.

On Monday, Mr. William Carter, coroner for East Surrey, held at inquest at Brixton on the body of Alice Maud Holland, aged one month, the illegitimate child of a domestic servant. The child was being brought up by a Mrs. Segar. According to the statement of Mrs. Segar, the deceased on last Wednesday night appeared to have a slight attack of bronchitis, and having some laudanum in the house which she was in the habit of using for her toothache, she put three drops in the deceased's milk and gave it to her. The deceased fell into a deep sleep, and, as she did not appear to wake up next morning, Mrs. Segar became alarmed and called in a neighbor, and by the advice of the latter the deceased was taken to Dr. Clark's surgery and received medical treatment. The child, however, died the same night. The jury, after consulting in private for some time, returned a verdict of "Death by misadventure," and censured Mrs. Segar for administering the laudanum to the deceased.—*Chemist and Druggist*, August 27, 1887.

An Imbecile Punished.

At the Herts Summer Assizes, August 3d, a laborer was indicted before Mr. Justice Hawkins for setting fire to a certain stack of wheat straw. The act was admitted, but the plea of insanity was set up. Dr. Lipscombe, the medical officer of St. Alban's Prison, stated that for six weeks he had frequently examined him. He had arrived at the conclusion that the prisoner was an imbecile. He could not talk coherently, there was no sequence in his ideas, and his gait was unsteady. He did not know what he was about. He suspected that the man had been weak-minded all his life. The prisoner had said in reply to a question as to his age, that it was three years. A veterinary surgeon, Mr. Herbert Matthews, of Stevenage, said he had known the prisoner for nearly thirty years, and during the whole of that time he was looked upon as a sort of imbecile, and went by the name of "Silly Billy." The prisoner's brother said that he (the witness) managed the little property he had because he could not manage his own affairs. He believed he knew the difference between right and wrong. Mr. Justice Hawkins said, as in duty bound, that a man could not be exonerated unless he was absolutely incapable of knowing right from wrong. The jury found him guilty, but strongly recommended him to mercy. The prisoner was sentenced to imprisonment

for twelve calendar months with hard labor. This case is another instance of the injustice of the legal test of responsibility, which the judge simply applied in all its naked absurdity, the result being the punishment of an imbecile with hard labor. Such a sentence may have its use in opening people's eyes to the unsatisfactory state of the law, but that the unfortunate man should have to suffer as a victim is rather hard lines. We should have thought that this was pre-eminently a case in which the "Crown referee, in cases of supposed insanity," would have been consulted, but there is no reason to suppose this has been done.—*Brit. Med. Journ.*, August 27, 1887.

Poisoning by Datura Seeds.

A somewhat remarkable case of poisoning a husband, a double murder, in fact, is reported from Bombay, by mixing the seeds of datura with the bread prepared by the wife for the daily meal. The circumstances under which the murder took place are as follows: On the 12th April last, Moti Ludha, the husband of the guilty woman, one Reh-moo Vullee, a dealer in ghee, and a young woman named Rasul, left their village of Sela in the morning for the purpose of fetching ghee from another village. Halting outside the first village they came to, they sat down to partake of their frugal meal. The girl sat apart and ate her *bajri* bread, while the two men sat and shared their own bread together, and gave the fragments to the girl, who subsequently made them over to the police. Later in the day, as the party were proceeding in the afternoon towards Checkla village, the two men became giddy, began to stagger, and behaved like madmen. They soon became speechless, and fell down on the road. The girl ran for assistance to the village of Checkla, but on her return both men were found dead. A post-mortem examination showed that they were poisoned with datura seeds, as they were detected in the pieces of bread left uneaten. The bread had been prepared by the accused for her husband the night before he started on the journey. The prisoner was found guilty of murder and sentenced to death, subject to the confirmation of the High Court. The motive for the murder was that this woman was carrying on an intrigue with another man, and wished to get her husband out of the way. It is understood that it was the freshly gathered seeds of *Datura stramonium* that were introduced into the bread, and if so their toxic action

appears to have been unusually rapid, or the Indian-grown plant must contain a larger quantity of daturine than that of this country. This latter substance, it is well known, has an action very similar to that of atropine, and the fresh extract of stramonium is more powerfully poisonous than the green extract of belladonna. It is not improbable, however, that in this instance the fresh fruit of belladonna itself was used. The report of the case is very meagre, and by no means clear on this point.—*Med. Press and Circular*, August 24, 1887.

Dressing for Broken Finger.

At a recent meeting of the Philadelphia County Medical Society, Dr. A. C. W. Beecher reported a case of simple fracture of the distal phalanx of the index finger, which he treated by applying a narrow bandage from the end of the finger to the second phalangeal joint, making two layers. This he coated thickly with collodion, which, drying and hardening quickly, made a neat, smooth, and stiff waterproof casing, which was worn with but one change until the fracture was cured.

How Much a Man Eats.

Richard A. Proctor, in the October *Cosmopolitan*, says: It has been calculated that, on the average, each man who attains the age of three score and ten consumes during the course of his life twenty wagon loads of food, solid and liquid. At four tons to the wagon, this would correspond to an average of about a hundred ounces of food per day, or say some one hundred and twenty ounces per day during adult life and about eighty ounces during infancy and youth. Most modern doctors agree in regarding one hundred and twenty ounces of food per day, corresponding to five or six half-pints of liquid food, and seven or eight pounds of solid food, as in excess of the real daily requirements of a healthy man or woman.

Yet probably most of us take more than this, in one way or another, during the day. Dr. Lankester from an extensive analysis of the dietary of soldiers, sailors, prisoners, and the better paid classes of artisans and professional men in London, found the average daily quantity of solid and liquid food to be one hundred and forty-three ounces. Doubtless many take much less; but unquestionably many take much more than this. When some one mentioned before Sydney Smith the twenty wagon loads of food calculated for each man's allowance, he turned to Lord

Durham, who like himself was corpulent (and not without sufficient reason), with the quaint remark, "I think *our* wagons, Durham, must be four-horsed ones." There are members of the London Corporation, to seek no further, whose wagons must be six horsed ones, and well loaded at that.—*Cosmopolitan*, October, 1887.

Acids in Canned Goods.

T. P. White sends to the Chemical Society a communication, noted in the *Popular Science Monthly*, in which he gives a decidedly negative answer to the question whether the acids of canned fruits may not form poisonous salts with the tin. He reports as the result of his experiments that "tin is entirely devoid of danger when taken internally in any form that might arise from being in contact with fruits or vegetables." He believes that the cases of accidental poison attributable to tin were due to solder or other impurities—arsenic, copper or lead. Professor W. Mattieu Williams says that there need be no lead in the solder; that is only put in for cheapness sake, and that tin makes a superior solder to any alloy. Therefore, all danger may be obviated by prohibiting the use of any other solder than pure tin.

Renal Calculi and White Wine.

Eichhorst says that a rare case has come under observation in which a distinguished surgeon is able, with absolute certainty, to produce renal calculi in himself by drinking white wine. Even a quarter of a wineglassful is sufficient. At the end of a few hours violent pains are experienced, and finally calculi are voided. They may attain the size of a pea, and are composed exclusively of uric acid. Symptoms of calculi are never produced if the ingestion of white wine is avoided.—*Am. Pract. and News*, October 15, 1887.

Boric Acid a Remedy for Sty.

Dr. Geo. Reuling says: I have found a simple and effective remedy for sty to be a solution of fifteen grains of boric acid to an ounce of water. By applying this solution three times a day to the inflamed part of the eyelid, by means of a camel's hair brush, this painful and annoying affection will be conquered very rapidly.—*Virginia Medical Monthly*, October, 1887.

CORRESPONDENCE.

The Conjugal Question.

EDS. MED. AND SURG. REPORTER :

Sirs :—The views expressed by your correspondent, Janet Rees, in the REPORTER, prompt me to pen a few thoughts in reply.

I believe that conception does not take place as often as is generally supposed, when the coitus is not actively participated in by both parties to it, and that therefore "love children" do not bear such a small proportion to the "accidental children." This result is favored by the fact that women are supposed to have a stronger sexual passion about the time of menstruation, when they are most likely to conceive.

As far as the mere pleasure of the parties is concerned, I fancy that uncongenial coitus depends more upon uncongenial union than anything else. Your correspondent describes the wife as accepting the attentions of her husband passively, after the first passionate happiness of the honeymoon is over, and especially after she has given birth to children. This implies the belief—which I do not share—that child-bearing alone materially alters the sexual instinct.

Nor can I believe that very serious injury would be likely to follow coitus in which a woman did not actively participate. Excessive indulgence may do harm, but passive acceptance could hardly produce the same results. Of course extreme repugnance and disgust might act unfavorably through the central nervous system.

It is usually the case that women who deny that they experience any orgasm, or pleasurable sensation, during the sexual act, are *impotent—functionally deficient*. Your correspondent certainly depicts a deplorable state of family affairs: the husband, full of lewdness and passion, forcing gratification from his helpless wife; the wife disgusted, annoyed, passively submitting to the husband's embraces, and even "feigning pleasure" for fear of alienating her husband's affections.

I doubt if in such cases the husband has any affection, and if so, it is as the writer says: his "passion and affection are one." But to think that such a state of affairs is at all common is, I believe, an insult to husbands as a class; and to assert it as a general truth that man's affection and passion are one is to insult the sex. The experience of advancing years affords the strongest contradiction to such an assertion. For, do we not constantly see, when the sexual appetite abates

with the declining years, the noblest examples of pure strong affection—the affection of the aged? As age advances, the sexes become—as in childhood asexual, but, with this, the love of husbands for their wives does not wane, but seems to grow stronger and purer than that of their passionate youth.

Yours truly, W. N. SHERMAN, M.D.
Kingman, Arizona, Oct. 18, 1887.

EDS. MED. AND SURG. REPORTER:

Sirs:—The frank expression of opinion on the delicate subject of the conjugal relation, by Janet E. Runtz Rees, in the REPORTER of Oct. 1, deserves, as you suggest, a fair discussion. The writer seems to have been unfortunate in her observations, but she might bear in mind that instances of alleged brutality on the part of the husbands must be taken with some grains of allowance. The women from whom this testimony comes are said to be sufferers from obscure nervous ailments. Now, experience proves many patients of this class are untrustworthy, and cannot be considered good witnesses. As an instance of forbearance on the part of a man, I will relate the following:

A young man and woman were married after a courtship of about a year. Both had been previously engaged, so that they knew about what marriage meant, and after marriage slept in the same bed until the birth of a child. When this child was old enough to be weaned, the wife moved into another bedroom and refused to have any further sexual relations with the husband, and the husband patiently accepted the situation. This man might be regarded by some wives as a model; he certainly was not a brute, in one sense.

If woman's condition is really so deplorable, as Miss (or Mrs.?) Rees thinks, and man is actually so unreasonable in his demands, there would seem to be an excuse for polygamy. The majority of men do not appear to be the worse for frequent indulgence, and, if women suffer, how shall they be relieved? If their task is too great with a husband for each, shall each husband be given two? If this be considered too brutal a suggestion because it considers only man's appetite, Miss (Mrs.?) Rees may be asked why, if the woman's pleasures during the honey-moon gets recognition, man's capacity for longer continued pleasure is to be ruled out?

Again. Do women really suffer so much? My experience does not lead me to think so. And, if they do, it is remarkable how well the most of them stand it. And how does

it happen that so many women who are the mothers of children, and have lost their husbands by death, put themselves in jeopardy a second time? Again, unmarried women present by far the most striking examples of nervous diseases. Who has not seen marriageable girls, moping, listless and dull, who after marriage permitted a normal sexual hygiene, became bright and cheerful; while their improved appearance became the subject of congratulation among their friends?

The intimation that the birth of one or two children destroys the sexual appetite in woman may depend upon some isolated observation; it does not seem to me to be warranted by any very large number of them. The truth seems rather to be that women dread the danger of conception and the inconveniences of pregnancy, the pains of child-birth and the cares of maternity. Some or all of these rob the act of coitus of all its attractions, which are natural to woman as well as to man. Is not this what really makes women hold back and gives its importance to the "Conjugal Question?"

Yours truly,
JAMES E. FREE, M.D.
Benezett, Elk Co., Pa.

Gleditschine.—Stenocarpine.

EDS. MED. AND SURG. REPORTER:

Sirs:—The fact, seemingly well proven by the experience of Drs. Claiborne, Knapp, Jackson, Mitchell and others, that the newly discovered alkaloid, gleditschine, is largely like cocaine in its power as a local anæsthetic, has prompted me to determine whether it has a value akin to the coca alkaloid as a stimulant in the treatment of opium habitués, and I am now experimenting in this direction, using a two per cent. solution, exclusively by subcutaneous injection.

That cocaine, hypodermically, is a valued aid in treating the opiate neuroses is beyond question, in my opinion; but it is not a specific, and should never be given for this purpose by the patient himself, be he physician or layman. Should gleditschine have a similar value it may be found free from the ensnaring danger of cocaine, though, assuming the fact of its stimulant power, this freedom from risk will not be likely; and we shall note, probably, in the not far future, baneful effects from its abuse, and gleditschine inebriety be added to the list of toxic neuroses.

It has been stated by Dr. Seward that "he has observed antidotal effects to gleditschine from morphia." And W. H. Mitchell

asserts, "it is a direct antagonist to morphine and opium, ten drops of the two per cent. solution neutralizing one grain of morphia or six of opium." Experiments on rabbits now being made by myself will, it is to be hoped, sustain these claims. The two per cent. solution can be obtained at a present wholesale cost of six dollars per ounce.

I shall be pleased to receive and report the experience which any reader of your journal may have on this subject.

Yours truly, J. B. MATTISON.
Brooklyn, N. Y., Oct. 15, 1887.

Is Gleditschine a Fraud?

EDS. MED. AND SURG. REPORTER:

Sirs:—Since asking you to announce that we were investigating at our laboratory *gleditschia triacanthos*, which it has been claimed contained an alkaloid of greater anæsthetic value than cocaine, and mydriatic properties superior to those of homatropine, we have discovered that the two per cent. solution with which experiments have thus far been made, and of which we obtained a supply from Messrs. Lehn and Fink, of New York, to whom we were referred by the discoverers, and which purported to be a solution of the alkaloid obtained from *gleditschia triacanthos*, contains six per cent. of cocaine, and a sulphate of a salt which it is suspected further experiment will prove to be atropia. We have been able to obtain from *gleditschia triacanthos* only an infinitesimal percentage of an active principle in an amorphous state, which on experiment has not shown mydriatic or anæsthetic properties.

Yours truly, PARKE, DAVIS & Co.

[In view of these statements it is not surprising that Drs. Seward and Mitchell obtained the results attributed to them in Dr. Mattison's letter.—EDS. REPORTER.]

Localized Sweating.

EDS. MED. AND SURG. REPORTER:

Sirs:—With reference to the "localized facial sweating," discussed in an extract in the REPORTER, Oct. 15, p. 518, I can adduce my son, a very healthy young fellow, eighteen years old, robust and athletic, whose nose sweats without apparent cause, while the rest of his body is perfectly dry. This is naturally a source of some annoyance to him, and of amusement to the family.

My son has never had any rheumatic attacks; and a bad sprain of the ankle at football was well got over a year ago. His mother was a sufferer from rheumatism, and died at

the age of thirty-five of a cardiac affection. I have been told that she used to perspire across the bridge of her nose; but I think this must have been in her girlhood, as I do not remember it.

Yours truly, G.
New York, October 18, 1887.

NEWS AND MISCELLANY.

Medicine as Taught at the School of Salerno in the Eleventh Century.

In an instructive and interesting paper read before the State Medical Society of West Virginia at its twentieth annual session, July 13-15, 1887, Dr. J. T. Cotton, of Charleston, W. Va., says: Thirty-four miles south-east of Naples, on the western coast of Italy, lies the once beautiful city of Salerno. Even now it presents a fine appearance, with its ruins of an old Norman castle facing the sea, and its background of graceful limestone hills. By the medical world Salerno will ever be regarded with peculiar interest as the place where the first dawn of science was perceived, when the long night of barbarism, which had settled over Europe for five centuries, began slowly to disappear. Gibbon, in that fine rhetorical vein so characteristic of his pen, thus pays tribute to this historic city: "The treasures of Grecian medicine had been communicated to the Arabian colonies of Africa, Spain and Sicily, and in the intercourse of peace and war a spark of knowledge had been kindled and cherished at Salerno, an illustrious city, in which the men were honest and the women beautiful. A school, the first that arose in the darkness of Europe, was consecrated to the healing art. The conscience of monks and bishops was reconciled to that salutary and lucrative profession, and a crowd of patients, of the most eminent rank and most distant climates, invited or visited the physicians of Salerno. They were protected by the Norman conquerors, and Guiscard, though bred in arms, could discern the merit and value of a philosopher. After a pilgrimage of thirty-nine years, Constantine, an African Christian, returned from Bagdad, a master of the language and learning of the Arabians, and Salerno was enriched by the practice, the lessons and the writings of the pupil of Avicenna. The school of medicine has long slept in the name of a university, but her precepts are abridged in a string of aphorisms, bound together in the Leonian verses, or Latin rhymes of the twelfth century." Thus far the eloquent historian, Gibbon.

We will now make a plain statement of facts. The origin of this, the most important source of medical knowledge in Europe in the early middle age, is involved in obscurity. It is known that Salerno, a Roman colony in a situation noted in ancient times for its salubrity, was, in the sixth century the seat of a bishopric, and at the end of the seventh century of a Benedictine monastery, and that some of the prelates and higher clergy were distinguished for learning and even for medical acquirements. But it has by recent researches been clearly established that the celebrated Schola Salernitana, as it was called, was a purely secular institution. All that can with certainty be said is, that a school or collection of schools gradually grew up, in which especially medicine was taught. In the ninth century Salernitan physicians were already spoken of, and the city was known as the Civitas Hippocratica. A little later we find great and even royal personages resorting to Salerno for the restoration of their health, among whom was William of Normandy, afterward called William the Conqueror of England. Several thousand students now thronged the streets of this great seat of learning, and the number of teachers was correspondingly multiplied. Among the latter many were married, and their wives and daughters appear also in the lists of professors. The most noted female professor was the celebrated Trotula in the eleventh century. Now I have the rare good fortune to possess, and shall be happy to exhibit to my medical friends here to-day, a perfect copy of the lectures of this veritable female professor, Trotula! printed and bound in the city of Venice in the year 1554, more than three hundred years ago, printed in an exquisitely clean Italic type, on most excellent paper, and the binding, though somewhat worn, battered, and defaced, yet still retaining marks of great beauty and finish. These lectures of Trotula are in Latin, then in universal use among the learned, and almost entirely free from the barbarisms and many impurities which had gradually crept into that language during the mediæval period. The title of this book is "*Trotula de mulierum passionibus*," Trotula on the Diseases of Women. It consists of sixty-three chapters, or divisions, going regularly and systematically over the whole field of gynæcology, as far as it was then known. My reason for describing this book so particularly, is for the purpose of correcting the serious mistake of Prof. William Goodell, of the University of Pennsylvania, in an elabo-

rate article contributed by him to the *American Journal of the Medical Sciences*, for Jan., 1871. In this paper, entitled "A Critical Inquiry into the Management of the Perineum during Labor," Prof. Goodell repeatedly refers to this book as a mere fragment, and relying upon certain German, French and English authorities seems uncertain as to the time when, the place where, and the person by whom it was composed. I will first quote the passage in full, and then point out the errors into which this learned professor has fallen. We next come, he says, to a fragment entitled "*De Passionibus Mulierum*," which describes complete laceration of the recto-vaginal septum and its treatment in the following language: Sunt quadam qua ex gravitate partus incidunt in rupturam pudendorum. Postmodum rupturam intra anum et vulvam tribus locis vel quatuor suimus cum filo de serico. This interesting fragment contains probably the earliest authentic mention of a complete laceration of the perineum, and is also the first to give a method for both its cure and prevention; unfortunately neither the name nor the time of the author is known. The learned Gessner deems this fragment to be the composition of Eros, a freedman of Julia the debauched daughter of Augustus Cæsar, anno domini 10. Astruc, Denman and Velpeau attribute it to Eros, surnamed Trotula, a midwife of the school of Salerno, anno domini 1250, whilst Renzi and Darenberg place her in the year 1059. On the other hand, Sir Alexander Cooke says Trotta or Trotula is allowed to be a forgery, an opinion confirmed by Sprengel, Portal and Gruner, who assert that this fragment is neither by Eros nor by Trotula, nor by any pagan physician, but by some christian physician of Salerno.

Now from internal evidence alone furnished by the book itself it is manifest that every one of these statements is wrong excepting that made by Renzi and Darenberg, who place her in the year 1059.

It can only be explained on the ground that these eminent scholars and learned physicians had never met with a perfect and complete copy of the lectures of Trotula, but only with some fragmentary portions of it. That the author of this book was a resident of Salerno is evident from the frequent references in it to the manners and customs of the Salerno women, describing the various preparations which they used for coloring the hair, and for improving their complexion. For instance, in the sixty-first chapter and on page 513, we are told the women of Salerno put the root of Viticella,

that is of bryony, in honey, and with this anoint the face, and thus produce a wonderfully brilliant complexion.

There are other allusions to the women of Salerno, but I deem it unnecessary to multiply quotations, and will next attempt to show from the book itself the precise period of its author's existence. On page 515 we find this statement:

"For I myself saw a Saracen woman who relieved many women of offensive breath by directing them to hold a small quantity of laurel leaves and musk under the tongue." Again on page 513 we are told: "The Saracen women are in the habit of coloring or staining their faces with a certain composition made after this manner: Take that kind of seaweed which the Saracens use to impart a green color to the hides or skins of animals; boil this weed in a new earthen vessel, with the white of an egg, one-third part; then strain it, and add some well cut up pieces of bresilium and again boil, and then set aside to cool. Afterward put in some pulverized alum and pre-serve the mixture in glass or golden vessels for future use."

These and other references to the Saracens plainly show that the writer of this book had met and conversed freely with this remarkable people. Now it is a well established historical fact that the Saracens, who had held possession of Salerno for several years, were conquered and finally expelled from that city, and indeed from southern Italy, in the year of our Lord, 1080, by Robert Guiscard, the great Norman chieftain. Another inference to be drawn from the quotations already given refers to the sex of the writer. For the Mohammedan law, which has always been rigidly enforced, absolutely prohibits male physicians from seeing or converging with the occupants of the harem. But aside from this, that the author was a woman is conclusively proved by the curious and remarkable fact that of all the sixty-three chapters contained in the book, going over the whole ground of the diseases of females, by far the largest and most elaborate chapter is devoted to the instruction how best to beautify and adorn the person; how, for instance, to whiten the face and clear up the complexion, and how to make the hair long and black or yellow, or white or golden, in accordance with the taste or desires of the patient.

American Public Health Association.

The American Public Health Association will convene at Memphis, Tenn., Tuesday, November 8, at 10 o'clock A. M., and con-

tinue four days. The meetings will be held in Young Men's Hebrew Hall.

The Executive Committee have selected the following topics for consideration:

I. The Pollution of Water-Supplies.

II. The Disposal of Refuse Matter of Cities.

III. The Disposal of Refuse Matter of Villages, Summer Resorts, and Isolated Tenements.

IV. Animal Diseases Dangerous to Man.

These topics are exceedingly important, and apply to every section of the United States and the Provinces. Therefore it is expected that sanitarians, and others who have had experience and observation in these matters, will give their views to the association, and through it to the public.

Applications for certificates to enable members and those intending to become members, and their families, to obtain the reduced rates offered by the various railroad lines to Memphis, should be made without delay to the Committee of Arrangements, Dr. G. B. Thornton, Chairman, Memphis, Tenn.

All reports and papers must be in the hands of the Secretary by November 7th in order to receive the approval of the committee. After November 1st all communications to the Secretary should be sent to Memphis, Tenn., care of Dr. G. B. Thornton.

The Secretary would like, at the earliest moment, the names of all members of the association who have died since the last annual meeting, in order that proper mention may be made.

Clergymen, teachers, engineers, architects, builders, and all interested in the practical work of the association, are cordially invited to be present.

Condition of the Crown Prince of Germany.

Dr. Makenzie said on Oct. 12: "The Crown Prince's general health is good, but there are symptoms which cause anxiety. The chronic catarrh of the larynx tends to induce acute inflammation of the windpipe. The Crown Prince had such an attack, accompanied by high fever, during his stay at Toblach. The acute inflammation of the windpipe was speedily cured by treatment. The southern climate has also had a good effect, but the acute inflammation of the mucous membrane makes us fear a recurrence, in which event inflammation of the deeper-lying tissues may occur, which might cause changes in these tissues."

—Illinois has passed a law making the inter-marriage of cousins a penal offense.

Yellow Fever at Tampa.

Dr. Wall, President of the Health Board of Tampa, Florida, telegraphed, on Oct. 11, to Surgeon-General Hamilton, in reply to an inquiry as to the nature of the disease there: "It is unquestionably yellow fever, though popular sentiment of those remaining here is against me. Albumin in the urine, with the characteristic icteric hue. One death yesterday (10th). It is all over the place, and the city authorities are doing nothing." Three new cases and one death were reported Oct. 10th. The fatal case was marked by the characteristic black vomit.

There was a light frost at Jacksonville, Florida, on October 22. Quarantine against all points in South Florida except Tampa and Hillsborough county has been declared off by the Jacksonville Board of Health, and this example has been followed by other cities of the State. A rigid cordon will, however, be maintained around Hillsborough county, and it is believed that there is now no danger of the disease spreading outside of Tampa.

The Western Pennsylvania Medical College at Pittsburg began its second annual regular course on Tuesday, September 27th, with a class of near 100.

The introductory address was delivered by the Secretary of the Faculty, Professor W. J. Asdale.

This college requires an entrance examination, and provides a three years' graded course.

A Fifty Dollar Prize.

The *Pharmaceutical Era* offers a prize of fifty dollars in gold for the best essay on the relations of the pharmacist to the physician. The essay should endeavor to show how the ideal harmonious relations between physicians and pharmacists, both as individuals and as represented in their respective organizations, may be best realized, and all competitors must be governed by the following conditions:

1. Any one interested in the subject may compete.
2. The essay must not exceed 2000 words in length, and must reach us previous to January 1st, 1888.
3. The MSS. must be free from the author's name, address, or other marks of identification, and we recommend typewriter copy wherever practicable.
4. The author's name and address must

be enclosed with the manuscript on separate paper.

5. All the essays submitted in competition for the prize are to be the property of the *Pharmaceutical Era*, and to be published or not at the discretion of the editor, but names of authors will be suppressed if requested.

6. A committee consisting of five representative men chosen from the medical and pharmaceutical professions, to whom the essays shall be submitted anonymously, shall award the prize, and the names of the committee will be announced with their decision.

Congress of American Physicians and Surgeons.

A meeting of the Executive Committee of the Congress of American Physicians and Surgeons, for the purpose of organization, was held on October 5th, in the Hall of the College of Physicians of Philadelphia. The special societies were represented as follows:

American Surgical Association, Dr. Claudius H. Mastin, of Alabama; *American Otolological Association*, Dr. Cornelius R. Agnew, of New York; *American Ophthalmological Association*, Dr. D. B. St. John Roosa, of New York; *American Laryngological Association*, Dr. J. Solis Cohen, of Pennsylvania; *American Neurological Association*, Dr. L. Carter Gray, of New York; *American Dermatological Association*, Dr. I. E. Atkinson, of Maryland; *American Climatological Association*, Dr. A. L. Loomis, of New York; *Association of Genito-Urinary Surgeons*, Dr. John P. Bryson, of Missouri; *American Association of Physicians*, Dr. William Pepper, of Pennsylvania.

The Committee was organized by the election of Dr. Pepper as Chairman, and Dr. Bryson as Secretary.

It was decided to hold the Congress of 1888 in Washington, D. C., on Tuesday, Wednesday, and Thursday, September 18th, 19th, and 20th, respectively. The sessions of the Congress will be held in the evenings, leaving the mornings and afternoons free for the sessions of the special societies participating. The following officers were elected: *President*.—Jno. S. Billings, M.D., LL.D., U.S.A., of Washington, D. C. *Vice-Presidents*.—The Presidents-elect of all the participating societies. *Treasurer*.—Dr. W. H. Carmalt, of Connecticut.

The arrangement of the programme for the sessions of the Congress was referred to the President, the Secretary, and the Chairman of the Executive Committee.

An Unsanitary Prison.

Dr. Hunt, of the State Board of Health of New Jersey, states that the Camden prison is without a parallel in the State, and, as far as he knows, in the country, as regards the miserable construction of its underground, unlighted and unventilated vaults.

He further says: "The Camden jail is so much a place of demoralization and of consignment of persons to filth and degradation that we should be untrue to the decent and humane sentiment of the citizens of this State if, after repeated reports and persuasions we should not most emphatically protest against the continuance for another winter of such quarters and accommodations for human beings." He declared it to be the duty of the board to seek an injunction from the courts against further occupancy of the underground cells by prisoners.

County Physician Gress also, in his report, states that although there had been some improvements made the ventilation was abominable and the atmosphere and the darkness fetid.

The *Brit. Med. Journal* states that Sir William Gull, the eminent physician, was stricken with right-sided paralysis on October 15. His physicians report a gradual improvement in his condition.

Items.

—The New York Quarantine Commissioners have issued a circular, saying that they are "fully able to protect the city from cholera, so far as any apprehension from the Alesia's passengers is concerned."

—A telegram from Ishpening, Michigan, says the Iron Mountain village, on the Menominee River Railway, on October 18, that there were 200 cases of typhoid fever. Many deaths have occurred. Poor water and defective sewerage are generally blamed for the epidemic. A panic prevails, and many persons are leaving the place.

—Minnie Demor, seventeen years old, the adopted daughter of James Henderson, of Manistee, Michigan, has confessed that she smothered the baby which died suddenly a few weeks ago, because she did not want to nurse it. She poisoned the cows, so that she would not have to milk them, and set fire to Henderson's house five times. Here is a case which seems not unlike moral insanity.

—A white, sweet-tasting powder, said to consist of a soluble borate of magnesium, prepared by a special process, has been in-

troduced under the name "Antifungin" as possessing extraordinarily powerful disinfecting properties, and as being a specific against diphtheria. It is said to be soluble in four parts of boiling water, and it is used in form of a fifteen per cent. solution. From five to twenty drops, according to age, are administered every one or two hours, and about a teaspoonful is sprayed hourly in the sick-chamber. Further, the diphtheritic growth is painted with the solution every one or two hours until it disappears.—*Am. Druggist*, Aug. 7, 1887.

Marriage Notice.

SUNDBERG—BLACKMANN.—In San Francisco, Cal., by Rev. Geo. W. Izer, D. D., Dr. John C. Sundberg of San Francisco and Miss Ciara L. Blackmann of Los Angeles, Cal.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Oct. 16, 1887, to Oct. 22, 1887:

Major W. D. Wolverton, Surgeon, detailed as member of Army Retiring Board at Washington, D. C., convened by S. O. 78, A. G. O., April 5, 1887, vice Major C. C. Byrne, Surgeon, hereby relieved. S. O. 241; A. G. O., October 15, 1887.

Capt. Edwin F. Gardner, Assistant Surgeon, relieved from duty at Ft. Reno, Indian Ter., and ordered for duty at Ft. Lewis, Col. S. O. 241, A. G. O., October 15, 1887.

Capt. John J. Cochran, Assistant Surgeon, now on duty at the Presidio of San Francisco, Cal., is assigned to temporary duty at Headquarters Division of the Pacific as Assistant to the Medical Director of that division. S. O. 244, A. G. O., October 19, 1887.

First Lieutenant C. B. Ewing, Assistant Surgeon, granted leave of absence for one month, on surgeon's certificate of disability. S. O. 112, Dp. Mo., October 18, 1887.

Appointment:

Nathan S. Jarvis, to be Assistant Surgeon, U. S. Army, with the rank of First Lieutenant, October 14, 1887.

Changes in the Medical Corps of the Navy for the week ending October 22, 1887:

Passed Assistant Surgeon H. G. Beyer, ordered to hold himself in readiness for orders to the "Trenton." Assistant Surgeon S. S. White, ordered to hold himself in readiness for orders to the "Trenton."

Passed Assistant Surgeon F. B. Stephenson, detached from the "Bache" and ordered to the Navy Yard, Boston.

Assistant Surgeon E. P. Stone, detached from the "New Hampshire" and ordered to the "Bache."

Surgeon T. H. Street, detached from the "Patterson" and placed on waiting orders.

A Naval Medical Examining Board is now in session at the Naval Hospital, Philadelphia, Penn., for the purpose of examining candidates for admission to the Medical Corps of the Navy. Circular of information can be obtained on application to the President of the Board.

There are twelve vacancies in the list of assistant surgeons.

TRICHINIASIS—NINE CASES.

BY G. W. FUREY, M. D.,
SUNBURY, PA.

It has been my lot to be called to attend this, the only case, or group of cases, of this peculiar, tedious and dangerous disease, ever known to have occurred in Central Pennsylvania.

Owing to the fact that I was entirely mistaken in my diagnosis of the first stage of the first case presented, and that this disease fortunately *is* a very rare one, though liable in the practice of any physician to confront him with its mysterious, unintelligible and apparently harmless symptoms, I will endeavor to report my recent experience, as well as my memory and the few notes I was able to take, will admit.

I shall discuss the disease in a general way first, and then in detail the phenomena presented to me in a study of the first of the five cases.

About the 9th of December, 1880, a young man, H. L., by name, aged twenty-six, car repairer, called on me for treatment for what he described, and which I believed, to be a bad cold. I prescribed the usual remedies for it, telling him not to go to work for a few days. The next day I was sent for to attend him, and also other members of the family with which he was boarding. I was at once struck with the strange similarity of symptoms between him and the others; and concluding that a "bad

cold" never appeared so uniformly at once, and in so many cases, I became impressed with the conviction that I had to deal with some unfamiliar specific affection, or the result of some ill-marked poisoned condition. A search of the premises, an investigation into the manner of living, condition of the heating apparatus, cellar, out-house, etc., soon restricted my suspicion to something which they had eaten. The peculiarity of muscular "lameness," and the unanimity with which they were complaining of it, suggested *Trichiniasis*. I asked to see the pork they were eating; was shown the barrel, and on examining some of its contents was at once struck with its singular *leanness*, and peculiar pale, un-pork-like color, and general appearance. They told me that they had bought the hog of a butcher, dressed; that it weighed three hundred and seventeen pounds; had frame enough for four hundred and fifty pounds; that it might have been a "native" or a "western" hog.

I put the five patients on the treatment which I will mention, and requested them not to eat any more of the pork until told to do so. I removed several small pieces of the meat, and called upon Professor G. G. Groff, M. D., of Lewisburg University, for the use of his microscope, and for his assistance. After careful search, we were rewarded by finding in abundance—five in one field—*Trichina Spiralis*.

The five cases collectively presented the characteristics stated by writers upon the subject, though individually they did not, with the exception of the first case I saw. In all there was early languor, oedema of the face and eyelids, hoarse-

ness and irritable fauces; while in only two was there any noticeable swelling of the extremities. Only one was troubled with profuse perspiration; but one had gastric trouble; one was distressed for a few days with colic, neuralgia and diarrhœa; two had considerable bronchial trouble; all had more or less congestion of the conjunctivæ, with corresponding lameness of the orbital muscles. The febrile stage—present in all the cases—also varied in degree and duration. Only one approached anything like delirium (H. L.), and he presented a very marked degree of disturbance of muscular and nervous coördination. The cephalalgia varied somewhat as to situation: being in the anterior portion of the head in all, while two in addition had very severe pain in the posterior part. My attention was drawn to the constant presence of a special lameness of the trapezius muscle. Next to be complained of were the deltoid and brachialis, and those of the lower extremities. All had difficulty of deglutition.

I noticed in the morning a marked intermission of fever, but especially of the soreness, with a want of appetite. The two specially troubled with bronchitis, were also specially sore in the region of the inter-costal muscles and diaphragm. The distress, too, corresponded with the movements of the body, and direct pressure on the muscles. The case of I. W. suggested to me the belief that the intensity of the disease depends considerably upon the amount of parasites ingested, he being under dietetic restrictions for indigestion; and in consequence had eaten sparingly of the infected pork. Another reason for these cases being so mild, according to this same idea, is that the family had been eating of a quarter of beef, and had only indulged in a few dinners of the *boiled pieces* of the pork. That they had eaten of the large pieces, will account for the non-destruction of parasites lying deep down in the muscles, and therefore my five cases of trichinosis, which would never have occurred if the meat had all been sliced thin and well cooked. I have been impressed more than by anything else, with the conviction that it requires either a very considerable previous experience with the disease, or a *group of cases and a microscope*, to establish a diagnosis.

When we consider that a man may have trichinosis and not be confined to bed; not "sweat profusely," not "cough extensively," nor even suffer from "nausea," nor "diarrhœa," the inefficacy of book descriptions,

in one's first case at least, is very apparent. I mean that all the works I have read on the subject have considered only typical cases, while here in one family, three of whom were of the same family habits, and condition, I found only one typical case, while the other four were so ill-marked and moderate that I should never have suspected any one of them, alone, of having trichinosis. For further assurance that we ought to be on the alert for such contingencies, it is only necessary to say that while I have been attending my five cases, I have read in the papers of seven cases in one family, and four in another, in Franklin, Erie county, Pennsylvania, who were treated for typhoid fever until six of the first seven died, before it was ascertained that the disease was trichinosis; and also of one, a butcher in New York, who was taken sick with a brief illness, and underwent the most modern approved treatment for rheumatism.

I have already mentioned that of my five cases there was only one typical case; and I have pointed out the most essential points in which the others differed from it; so that by referring to the general description, and comparing them with the record I propose giving of the first and worst case, it will obviate the need of reporting all.

H. L., aged twenty six, began to feel languid and distressed on Sunday, December 5, 1880. Concluding that he had only a cold, he resumed work as usual on Monday, Tuesday and Wednesday. Thursday morning, the 9th, he felt entirely unable to go to work. He called on me for treatment for "his cold," and I prepared some medicine for a *cold*. Yet, I was not exactly clear as to the cause of the peculiar œdema of his hands and face; which he told me had showed itself on Monday. Friday evening I was called to see him and others of the family where he boarded. It was at once apparent that even a very bad cold would not account for his symptoms. His temperature was $103\frac{1}{2}^{\circ}$, pulse 100; face, much swollen; cough, dry and irritable; bowels constipated. Tongue not coated. Considerable pain in anterior and posterior part of head. A dull, indescribable pain, or lameness in the muscles of the back, arms and limbs, and considerable distress occasioned by efforts at respiration. He preferred to lie on his back. I noticed no indication of flexion of the extremities. The fever began on Wednesday evening the 8th, and continued until Sunday. The œdema mentioned, which had attained its maximum by the 12th, wholly closing both eyes, was entirely gone

by the 15th. On the 12th I noticed that the dry, irritable cough brought from his throat a tenacious sputa considerably mixed with blood. The discharges from the nostrils, though not so tenacious, were also colored. This peculiar symptom also affected in the same manner one of the other patients, a brother. During the time it remained, which was about six days, he complained of dryness of the throat, and a prickling sensation. Profuse diarrhoea began on the 15th, lasting to the 21st. The sweating was first complained of on the 17th and continued till the 24th. It was worse at night. There was considerable emaciation.

When I first suspected trichinosis, I ordered thorough evacuation of the alimentary canal, which was followed by large doses of quinine. Then when I found the parasite unmistakably in the pork, I began the use of as large doses of sulpho-carbolate of soda as the stomach would bear. This, with a liberal diet, and ammonia liniment externally, constituted the treatment. Forty-two days after the first attack, I considered him to be out of danger and able to resume his work.

In the face of the discouragement afforded me by the perusal of several works on the subject, Ziemssen's Cyclopædia, for one of them, I must, with all deference and some modesty, affirm that were I to be called again to attend a similar case or group of cases, instead of pursuing the weird and shadowy pathway offered me by the authors referred to, I should, and I think conscientiously, follow my above-mentioned treatment.

The foregoing cases occurred in the fall of 1880. In the fall of 1885 a German, having supplied his larder with plenty of "city-cured hams," proceeded, as a matter of course, to slice one of them off, and eat of it raw. In a few days his family physician was called in to attend his little eight-year old daughter. In the course of treatment, consultation was had, and the child treated for rheumatism. After suffering terribly for about a week, she died. About this time the father and a little son, aged five years, began to manifest symptoms similar to those the little girl complained of at first. I was sent for, and after getting a description of the girl's case, together with all the attending circumstances, immediately pronounced the trouble to be trichiniasis. The father gave me no difficulty at all; but it was far different with the little boy. He rapidly developed all the classical symptoms and more too. I had no hopes of his recovery; but, after following the treatment I have mentioned above, with the

addition of santonine, I was rewarded by a complete recovery of both my patients. I verified the diagnosis by examining the faecal matter under a lens, the ham which caused the disease having been all eaten.

Two years ago this fall, I was called down to Bethlehem, to see the two surviving cases of that sad group of trichinosis. The mother, and thirteen-year-old daughter had recently died of it. I found the father, though not confined to bed, suffering very much indeed, while the little five-year-old girl was lying very low. The same treatment was ordered as the above, with, of course, tonic and sustaining measures. Both recovered, and when they visited me, a year after, were enjoying usual health.

The mother and daughter who died, were, I was informed, treated for rheumatism during the first part of their sickness, which teaches the lesson that it is necessary to be extremely particular in diagnosing rheumatism. To Mr. Eugene A. Reau, of Bethlehem, the accomplished microscopist, is due the credit of first suspecting and demonstrating these cases to be trichinosis. He prepared some of the best specimens, both photographs and slides, from muscles of the patients who died, that I ever saw. No doubt he would be willing to furnish them to any person desiring them.

The facts in this report are: In the space of five years, in my practice, I have encountered three groups of this troublesome affection, in which, every time, the first cases were mistaken for something else. Three cases, associated with the nine I treated for trichiniasis, and which were treated for rheumatism, died. The nine subjected to the treatment I have mentioned, recovered completely. I do not wish to imply that it is infallible, or that I think it is; but I would certainly rely on it were I called to see other cases. I would be pleased to correspond with any physician who has had experience with the disease.

IT WAS NOT THE EDITOR.—"Can you tell me where I can find the man who wrote this article?" asked an enraged individual of the city editor. "I want him discharged immediately."

"I really don't think you could have him discharged," replied the city editor, cautiously.

"Why not, sir? I demand it."

"Well, you see, the proprietor of the paper wrote that article. You might go and ask him to suspend publication, however."—*Washington Capital*.

ACUTE RETROVERSION OF THE UTERUS.

BY JOHN M. KEATING, M.D.,
PHILADELPHIA.

I have met with three cases in a short time which have been so interesting to me that I deem them worthy of your consideration. The first patient was a young girl, aged 20, unmarried, to all appearances in good health. I had attended her family, though I had never prescribed for her personally. She was strong and robust. She was most constant in her attendance upon a very ill brother. I was summoned one day in great haste and found her suffering excruciating agony, referred to the rectum, with constant bearing down and symptoms of such severity as to demand immediate relief. I made a rectal examination at once and found, about midway between the outlet and the promontory of the sacrum, a round and elastic tumor, which I at once recognized as the fundus of the uterus. Her constant and uncontrollable bearing down seemed to be dependent upon the desire to extrude this mass, which was so firmly pressed against the bowel as to almost occlude its calibre.

By firm pressure, directing my force upward to the left, I was able to push the fundus beyond the reach of my finger, and relief from pain was immediately noted. An opium suppository, rest in bed for a day or two, and enemata to keep the bowels free, administered daily, was all the further treatment. My patient was soon as well as ever. The history of the case was that of constipation, frequent attempts at evacuation, which required a great deal of effort, causing more or less annoyance and pain. On the day in question she had been sweeping the room, and attempted to lift some heavy object, which caused her to use her abdominal muscles with some force; this was followed by the acute attack just noted.

Another case I give from notes of Dr. W. A. Edwards, with whom I saw the patient. "Fannie M., aged 18, a healthy mulatto girl, fell from a step ladder to the ground, a distance of perhaps five feet. She was immediately seized with sharp pelvic pains, and experienced a sensation as though something had given way. She was obliged to seek her bed. Forty-eight hours afterward her menses set in with extreme pain, her physician was called in, and treated her with opiates, etc., for one month. During this time there was a constant discharge of blood—sometimes

almost purely arterial; then mucus tinged with blood; and again active hemorrhage.

The patient continued about in the above condition, and her next period set in with increased pains; in fact, they were almost unbearable." She then consulted Dr. Edwards, whose notes continue as follows: "I was called in to see the case, and after quieting the pains by vaginal suppositories of opium, an examination was made. The genitals were extremely sensitive, the vagina hot and dry, the fundus was found posteriorly and low down; in fact the womb was turned almost upside down, and the examining finger first came in contact with the firm rounded fundus through the intervening vaginal wall. The os looked upward, anteriorly and toward the internal pubic ligament. The uterus was movable, but appeared to be incarcerated by the firm aponeurotic fibres of the pelvic ligaments. The patient was obstinately constipated, and experienced much pain and difficulty in urinating.

Recognizing the unusual character of the uterine displacement, a consultation was held with Dr. John M. Keating, who after examination confirmed the diagnosis, and we were enabled to restore the womb to its natural position by rectal and vaginal manipulation, with the patient in an exaggerated knee-chest position. Immediately the girl expressed herself as relieved from pain; she was able to have a natural fecal evacuation, the first in thirty-two days; urination was no longer painful, nor was the call so exacting. A well-fitting Smith-Hodge pessary was introduced, and worn for about fourteen days, when it was removed on account of giving some pain, and was not re-introduced as the case no longer demanded it. The girl has now entirely recovered, has no uterine symptoms whatever, and says that she would not know that she had a womb, had it not so recently caused her so much trouble.

Her menses are now regular and painless as they were before the fall. It may be of interest to note that this patient's mother suffered an acute prolapse of the womb while our patient was in utero; after reduction, however, gestation proceeded to full term."

A third case: I was sent for in haste to see a girl about thirty years old. She was a domestic, living at service; had previously been in perfect health; the only history was of constipation, as in the case previously noted. While washing windows, on attempting to push up an upper sash which required considerable force, she was suddenly seized with excruciating agony in the pelvic region, and constant bearing down which required

her at once to lie down. Applications were made to the abdomen, and within a short time the pain somewhat subsided. She did not see a physician, was able to walk a short distance to a friend's house. The next day she suffered intense pain, and then I saw her. Examination was made under ether. The uterus was found in a state of very acute retroversion, the fundus pressing down upon the bowel almost obstructing its calibre. It was impossible to push it up further than a short distance. In this position the patient was allowed to come from under the ether, an exaggerated knee-chest position assumed, and by exerting gentle but firm pressure, the fundus was finally pushed beyond reach and the uterus assumed its normal position. The patient was kept in bed for a few days with cotton tampons, opium suppositories, and injections of hot water, to thoroughly relieve the bowel which was very much packed. She finally recovered without further bad symptoms. It may be of interest to note that the patient about a year after, while arranging some Christmas decorations at a house at which she was at service, set her clothes on fire, and was so badly burned that she died in the Jefferson College Hospital.

I had frequent opportunities of examining this girl, and of studying her case carefully, and may state that the uterus was perfectly movable, normal in every way, and that the retroversion was very acute, and undoubtedly caused by the strain alluded to.

These cases certainly should be of interest, because they prove that such a condition of affairs can exist; though, as far as I know of, I have seen no report of such in the textbooks. Let us consider for the moment the anatomy of the normal pelvic tissue in young women, and then we can probably come at a better understanding of these cases.

Through the kindness of my friends, Dr. George McClellan, and Dr. J. B. Deaver of the University of Pennsylvania, I have been able to make some careful studies upon the cadaver. The conclusion that I have reached may be of interest to those who have seen cases like these I have reported. When I saw my first case I might have supposed that, with sudden effort, the fundus uteri had been pressed downwards and had gotten beneath the utero-sacral ligament of the left side and there become bound down. Theoretically, such a condition could exist, because the utero-sacral ligament, which is composed of a band of fibrous tissue covered by peritoneum, forms a distinct band when examined *in situ*. But I am satisfied that practically this condition of affairs can-

not exist, because the utero-sacral ligament is but a fold of fascia attached to the uterus at a level of the internal os, and running backward to the sacrum, becoming entirely obliterated when the uterus is turned backward either in a state of retroflexion or retroversion, and it then becomes impossible for the fundus to get caught beneath it. Of course, I am now speaking only of the pelvic organs of the virgin. The cases I have reported were all virgins. My observation has shown me that the space which normally exists between the uterus and rectum is usually filled with small intestine, the uterus clinging closely to the bladder, and rising and falling as this viscus becomes full or empty, the small intestine filling up this cavity and pressing downward upon the floor of the pelvis in the triangular space usually called Douglas's cul-de-sac, bounded by the utero-sacral ligament and the posterior walls of the uterus and vagina; the floor is the projecting portion of the rectum. This space is also frequently—in cases that I have studied, always—filled with small intestine.

It is interesting to note this especially, as the rise and fall of the uterus, which allows more or less tension upon these ligaments, depends upon the condition of the bladder. We can then readily understand how, in a case where the bladder is empty, and the uterus sunk into the pelvis, any sudden effort of the diaphragm and abdominal muscles may throw the force of the small intestine upon the uterus and force it backwards and downwards, very readily hold it there by the pressure of the bowel above, and give rise to the condition of affairs which we have noted in the three cases above related.

A short time since, I had an opportunity of examining carefully the position of the intestine during life. I removed the ovaries from a young unmarried woman of about 25 years, for disease of the tubes. The abdominal tissues were very thin; there was scarcely any fat. I made the initial abdominal incision, and when within the peritoneal wall, carefully passed my hand over the uterus and down into the cul-de-sac. A coil of small intestine, seated in the cavity, formed a cushion at the back of the uterus, and as long as this rested there, it would have been impossible for the uterus to have left its customary anteverted state and become retroverted. I was able to lift the intestines out of the way and place the uterus back in position; but I found no means of holding it there by catching it beneath any ligamentous tissue, as the broad ligament and the utero-sacral folds were relaxed.

This satisfied me that any sudden strain that would displace this intestinal cushion, especially if the bladder was empty, could force the fundus backwards, almost completely invert it, and the mass of the intestines, with their contents crowding on top, aided by the spasm of the abdominal muscles and those of the floor of the pelvis, could incarcerate the uterus.

LOCAL ANÆSTHETICS.

BY LAURENCE TURNBULL, M.D., PH.G.,

PHILADELPHIA.

To diminish or abolish the sensibility of the skin and mucous membranes in regions where surgical operations are to be performed, and to avoid the dangers of general anæsthesia is a matter of the greatest importance. One of the earliest and most efficient means of accomplishing local anæsthesia is cold; either ice or snow, with or without a mixture of the chloride of sodium, potassium, ammonium or calcium. Then we have the rapid evaporation of chloroform, ether, rhigolene, carbon bisulphide, absolute alcohol, benzol, and many other like substances, the action of which is expedited if they are applied in a fine spray.

Chloroform, ether, and the other allied substances before mentioned not only act on the peripheral nerves of the skin, and produce local anæsthesia, but anæsthesia may be caused by these agents by direct action on the nerve cells themselves. Thus Prevost found that chloroform applied directly to the brain of a frog narcotized it when the aorta was tied. When the aorta was released, so that the current of blood could wash the chloroform away, the narcosis disappeared.

The objections to these agents are that when the application has been made, and the operation performed without pain, there is a reaction if too freely used, by the return of the blood, with great force, pressing upon the nerves, or there is a partial death of the parts if frozen completely, so that the pain following is intense and prolonged. At times there is loss of the parts, also profuse hemorrhages. Still, with all these drawbacks, they can at times be employed with success, when no other agents are at hand.

Carbolic acid, painted over the surface of the skin or applied to a nerve exposed in a tooth, will cause it to become white and lose its sensibility, producing local anæsthesia.

In 1772, Percival introduced carbonic acid as a local anæsthetic to relieve pain, and the late Professor Dewees, of Philadelphia, recommended it in carcinoma uteri, also in

cancer of the rectum. In 1856, the late Prof. Simpson improved the apparatus so as to apply it with more efficiency.

The pain felt during the extraction of a tooth is lessened by the employment of violent muscular effort, as in grasping the arms of the dentist's chair. A still more powerful adjunct is electricity applied along the course of the nerves. The Faradaic or interrupted galvanic current was at one time employed in this city to produce local anæsthesia. This employment of electricity has been revived by Dr. I. Corning, of New York, by first perforating the skin with needles with the instrument of "Baunscheidt," and then applying over the surface a sponge electrode saturated with a two per cent. solution of hydrochlorate of cocaine. It should be kept connected with the battery from three to four minutes, and of sufficient intensity to cause a slight sensation of heat. It has been suggested that the method can be made more efficient if the surface be rendered almost bloodless by the pressure of Esmarch's bandage.

Hydrochlorate of Cocaine.

One of the most valuable and perfect of the local anæsthetics yet discovered is the solution of the hydrochlorate of cocaine applied to an abraded surface, mucous membrane, or hypodermically. Much has already been written and numerous experiments have been made in regard to the hydrochlorate of cocaine and its powers, under various conditions as an anæsthetic. Now after three years use of it we are better prepared to determine to what special cases it can be applied, and in what class it is either useless or injurious.

In September, 1884, the attention of the medical profession was first called to the anæsthetic properties of the hydrochlorate of cocaine by its discoverer, D. C. Koller, of the Vienna Hospital, who applied it to his own eye, and found it to produce entire insensibility to pain. Prior to this, its dilating effect on the pupil was known, and had been employed in laryngology, to diminish the sensibility of the throat; but it was reserved for Koller to make the valuable discovery for which all credit is due.

Soon after this I obtained a supply, and studied and experimented upon myself and many others, and collected all the published facts found in the medical press concerning its use.

Erythroxylon Coca; Folia Cocæ. The Leaves. Nat. Order: Erythroxylaceæ. Lamm. U. S. P. The coca is a small tree, 4 to 6 feet high, indigenous to the mountains of

Peru and Bolivia, and cultivated in both these countries on the eastern slope of the Andes, in damp warm valleys. The leaves are chewed by the natives to satisfy hunger, to strengthen the weak, to stimulate the nerves, and to remove depression or melancholy. The extract obtained by alcohol of 21° and 56° has all the gummy and resinous

EXPLANATION.

principles of the coca leaf, as well as the fatty nitrogenous principles, the tannin, the chlorophyl and the alkaloid. It is this extract which represents best, and in exact proportion, the *constituent principles of coca*.

Like tea and coffee, coca is used in nervous headache, and as a substitute for opium in opium habit. A similar use has suggested itself in the treatment of alcoholism, spermatorrhœa, generative debility, granular pharyngitis, and relaxation of the muscles of the larynx, pharynx and middle ear.

In man, Von Bebra states that coca suspends the appetite for food for some hours, and at the same time greatly increases the muscular strength and endurance. The celebrated traveler "Tschude" found when coca leaves were taken in infusion, it conferred a singular immunity from suffering, and prevented the hemorrhages which were apt to occur in the elevated passes of the Andes, some of which are 17,000 feet high. The experiments of Mason, of Boston, upon himself with the fluid extract of coca confirm some of the above observations. If used to excess, coca deranges the digestion and causes habitual constipation. The effects of coca may be summed up in its action upon man as a stimulation of the nervous system and retardation of metamorphosis:

The pure alkaloid "Cocaine" was extracted for the first time in 1855, by Gædeke, and subsequently after an improved method in 1860, by Nieman and Wöhler. It is in the form of fine prismatic crystals, colorless and odorless, of bitter taste, and it is easily soluble in alcohol and ether, but only in 704 parts of water. Its atomic formula is $C_{17}H_{21}NO_4$. The salts which have already been prepared are: The muriate ($C_{17}H_{21}NO_4HCl$), the sulphate, nitrate, tannate, salicylate and hydrobromate.

The chief salt now in use is the hydrochlorate. It is yellowish white, and appears in the shape of soft, silky prisms. It is almost insoluble in water, quite soluble in alcoholized water, and very soluble in alcohol and ether.

Ecgonine.—When cocaine is warmed to 100 degrees in a sealed tube with concentrated chlorohydric acid, it separates into two substances, viz.: benzoic acid, and a new base for which M. Woehler proposed the name Ecgonine. Ecgonine crystallizes in oblique rhomboid prisms, colorless, shiny, and containing one molecule of water of crystallization. Ecgonine is very soluble in water, less soluble in alcohol, and absolutely insoluble in ether.

Hygrine is a liquid alkaloid which M. Woehler discovered in treating Coca leaves with amylic alcohol. Its odor is like that of trymethyamine; it possesses a strongly alkaline reaction, and its taste is not bitter; its chlorohydrate is crystallizable, but deliquescent; with the bi-chloride of platinum it forms a flaky precipitate. A volatile principle has also been discovered in the fresh leaves which is lost when the dried leaves are employed.

The presence of hygrine and egonine in the hydrochlorate of cocaine may be detected by treating the salt with cold concentrated sulphuric acid. If the salt is pure, the result is a completely colorless solution. The impurities will stain the solution.

Cocaine in Ophthalmic Surgery.—Cocaine hydrochlorate has been found of priceless value in ophthalmic surgery. Experience has determined that a one per cent. solution is the proper dose for operations like cataract, and only one drop in the eye. The solution should be made fresh just before using it. If this cannot be done then a solution containing a minute quantity (gr. $\frac{1}{20}$) of bichloride of mercury, may be employed after keeping a few days, if made with pure distilled water. The injurious results which were published¹ from the use of hydrochlorate of cocaine in the practice of Drs. Keyser and Strawbridge, were owing either to the impurities in the solution or to its being too strong. It has been found by me that a strong solution will cause a feeling of roughening and will detach the epithelium of the eye. This will require an infusion of pith of sassafras, with camphorated tincture of opium (a teaspoonful in a coffee cup of the tea), to relieve the disagreeable symptoms. The following is an extract from Dr. Keyser's letter and his mode of using cocaine:

NOVEMBER 29, 1886.

"I have had no further mishaps with cocaine, and use it constantly for everything. I use only a 2 per cent. solution, and have it made in a saturated solution of boric acid."

In the early history of cocaine, experiments with it were very costly. One instance is reported in which six hundred grains were required to kill a dog. The cost of this experiment was one hundred and sixty dollars. The same number of grains can be obtained now for thirty dollars.

The cause of the troubles in the use of cocaine is either the use of too strong a solu-

¹ The New Anæsthetic, etc. By Laurence Trumbull, pp. 53. Pamphlet of 76 pages, published by P. Blackiston, Son & Co., Philadelphia, 1885.

tion, or allowing the patient to swallow the solution, which should never be permitted. Many persons forget when they are using a 10 per cent. solution, that there are 45 grains of the active hydrochlorate to one ounce of water.

The question of using a freshly prepared solution is of the utmost importance. Cases of irritation and inflammation after using solutions too strong or containing mould. Likewise the syringe must be kept scrupulously clean, and after washing and wiping, draw a few drops of equal parts of olive oil and liquid carbolic acid up and down the needle, then wipe it dry.

When cocaine is employed for the removal of cancerous tumors or other growths, the strength of the solution is increased to six or even eight per cent., but limited to the locality by a bandage.

When intra-laryngeal growths are to be removed, the best plan is to mix the cocaine in a powder of starch, boric acid or gum-arabic finely levigated. The powder is to be applied to the part to be operated upon, desiring the patient not to swallow any of it, but to expectorate it when it falls into the throat.

In ear operations, a much stronger preparation is used, from 10 to 20 grains to the ounce of solution of phenol or pure crystallized carbolic acid. It can also be employed mixed with lanolin, simple cerate, or vaseline, and applied to the parts.

Brucine, Lewinin, Apomorphine, Drumine, Gleditschine, (so-called Stenocarpine).

Having given briefly the most important results of the recent observations and experiments with cocaine, I now pass to the second part of our subject, the more recently introduced new local anæsthetics, Brucine, Lewinin, Apomorphine and the so-called Stenocarpine or Gleditschine.

Dr. Mays, of this city, introduced pure brucine as a local anæsthetic, and kindly furnished me with a solution in oleic acid. I made a number of careful experiments with it, and found it had some slight anæsthetic properties, but with the objection that when used freely on a mucous membrane or abraded surface it produced some of the symptoms of strychnia poisoning. It is true it is less powerful, and eliminated more rapidly than strychnia, but it has this one serious objection. The old idea was that the effect of brucine, in producing convulsions, was said to depend on admixture with strychnia, but Dr. L. Brunton found that pure brucine would produce convulsions

and death in rabbits when injected subcutaneously.

Lewinin is an alkaloid, allied to cocaine, but much inferior to it.

The objection to Apomorphia is that it causes very profuse secretions from the mucous membranes. It also acts as a poison on the muscular fibre of the ventricle of the heart like an acid.

Drumine has not been found of any value, except in the hands of the discoverer.

Gleditschine, so-called Stenocarpine.¹

The salt not being permanent, we have only obtained it in two per cent. solution. This new anæsthetic and mydriatic was discovered by M. Goodman, a veterinary surgeon of Louisiana, in the *Gleditschia triacantha*, which he describes as a tree growing to the height of thirty-five or forty feet, with a diameter—at the bole—of about eighteen inches, and a spread of foliage of about thirty to thirty-five feet. The leaves resemble those of the locust tree; the bark is smooth. From the ground up the tree is furnished with clamps of forked spines or thorns, the parent spine springing at right angles from the bough or trunk. As for the fruit, it bears pods eight or ten inches in length, flat and slightly curved, containing seeds and a viscid juice. The spines are very tough and highly polished, and the wood is extremely tough. It grows in clumps and singly, and is found in abundance in Louisiana.

It is not, as was supposed by Dr. Seward, the *Acacia stenocarpa*. The discovery of the anæsthetic properties was made by Goodman applying to the fetlock of a horse the leaves of what was known in Louisiana as the "Tear Blanket Tree." On making a free incision into the parts, there was no evidence of pain. He supplied some of the leaves to Dr. Allen M. Seward, a chemist of Bergen's Point, N. J., who separated by careful minulation an alkaloid. On testing a two per cent. solution on the eye of a cat it was found to produce local anæsthesia. A portion of this two per cent. solution was placed in the hands of Dr. J. H. Claiborne, who found that it produced anæsthesia in the eye of the rabbit, and in man with full dilatation of the pupil, and in some cases a diminution of intra-ocular tension; also anæsthesia of the mucous membrane of the nose and of

¹ Investigations reported since this paper was prepared for publication seem to prove that so-called gleditschine solution is a fraud, being a mixture of atropine, cocaine and some other undiluted substances.—EDS. REPORTER.

the skin, slight dulling of the sensibility of the tympanic membrane.¹

Dr. H. Knapp having obtained a small quantity from his colleague, confirmed his results with the exception of its influencing the sensibility of the skin, but we find that this depends upon the condition of the skin, as we have fully determined by employing both agents. The skin and tympanic membrane to be influenced must have the scarf skin removed by a strong alkali, or by chloroform; or its surface must be ulcerated, inflamed, or elevated from the cellular tissue beneath by fluid. Both cocaine and Gleditschia act alike in producing local anæsthesia by hypodermic injections.

In the experiments of my son, Dr. C. S. Turnbull, his assistant, Dr. Charles L. Weed, of Philadelphia, and the writer, the patient almost invariably complained of pain when the solution of the drug was applied to the conjunctivæ, for the space of from a few seconds to five minutes; then it ceased entirely. The pupil begins to dilate, and gradually assumes the maximum dilatation in the course of from five to ten minutes, causing after a time paresis of the accommodation, but not the dryness or pressure of cocaine. The mydriatic effect upon the pupil continues only about half the time of atropine. It has so far in some twelve or fifteen cases produced no tendency to glaucoma, as is apt to be the case when atropine is employed in a diseased eye. Glasses can be fitted, and make the patient much more comfortable in a much shorter period than when atropine was employed. No toxic results have followed so far in our hands with the use of a two per cent. solution of the so-called stenocarpin in the eye.

In experiments on frogs, according to the results obtained by Dr. Edward Jackson, of Philadelphia, a two per cent. solution was more powerful than a four per cent. solution of cocaine, and a frog was killed by two grains of a two per cent. solution.² In certain individuals of a hysterical or highly nervous organization, with a very open puncta, care must be taken not to allow a large quantity of the solution to pass into the nose and throat. It will be necessary in all cases to use but one-half the strength of the so-called stenocarpine that we employ of cocaine.

In a case of concussion of the retina with some exudation of lymph, and blood in the anterior chamber, the gleditschin did not

act and I had to fall back on a solution of atropine sulphate (gr. j to f5 ij), one drop every two hours; yet it relieved the pain.

Note of Caution.

Upon a careful evaporation of some of the two per cent. solutions of the so-called "stenocarpine or gleditschine," it was found that they contained a much larger per cent. of residuum than was proper. Also from the persistent dilatation of the pupil in other cases, it has been almost proven that certain other agents have been improperly added. It must also be borne in mind, that a great deal of doubt exists in the minds of chemists as to the true character of the agent employed in this solution. Another cause of hesitation has been the counterfeiting of certain labels of eminent chemists' products. In 1878 it is stated in the *Philadelphia Medical Times* that the late Dr. Lautenbach discovered an alkaloid in the Gleditschia triacanthus or honey-locust, but found no local anæsthetic properties in it.

LARGE DOSES.

BY LOUIS LEWIS, M.D.,
PHILADELPHIA.

Recklessness in the administration of large doses of drugs is always to be deprecated, but many medicines in our armamentaria may be judiciously prescribed in far larger quantities than has been hitherto sanctioned, in chosen and suitable cases. Delirium tremens and surgical shock may often be benefited by tincture of digitalis in one, two or even three drachm doses.

Succus conii is efficacious in chorea in ounce or larger doses. A drachm or even two of tincture of belladonna may be given in some cases of urinary incontinence; a child can take at least twenty minims with safety. Quinine may be and frequently is administered in half-drachm doses. Tincture of hyoscyamus renders good service in drachm doses, as also bromide of potassium. Large doses of iodide of potassium are frequently of immense value, in many instances.

Dysentery is shorn of much of its terrors by large doses—half a drachm or more—of powdered ipecacuanha. A dram of tincture of perchloride of iron is not too much sometimes in diphtheria and erysipelas. Five or six grains of sulphate of zinc can be given without nausea in chorea. Tincture of nuxvomica is safe and useful in twenty or thirty minim doses; and the liquor strychniæ of the British pharmacopœia, of which the

¹ *Medical Record*, July 30, 1887.

² Observations on the action of Stenocarpin by Edward Jackson, M.D., Philadelphia. — *Medical News*, September 3, 1887.

official dose is from four to ten minims, is often given in half-drachm doses in alcoholism with telling effect; this represents a quarter of a grain of strychnia. A drachm of antimonial powder has been administered with advantage. Heart troubles are frequently relieved by fifteen minim doses of tincture of aconite, three times in the day. Subnitrate of bismuth may be taken by the drachm in certain affections of the stomach, diarrhœa and dysentery. One drachm of chloroform is safe and useful for "worms." Phosphorus may be used in doses of one-twelfth of a grain without danger, so long as the urine is watched. Croton-chloral hydrate, originally prescribed in grain doses, relieves neuralgia in ten-grain doses, which may be repeated at intervals of four hours. Even a grain of morphia is often required several times daily, and sometimes every hour, in special cases; but of course great caution need be observed.

800 Corinthian Ave., Philadelphia.

STILL-BIRTHS.

BY H. V. SWERINGEN, A.M., M.D.,
FORT WAYNE, INDIANA.

I have often in former years been at a loss to account for the cause of still-births, occurring usually in primiparæ and when no physical or objective reason was furnished by the physique of the child or its mother, the presentation having been in the great majority of the cases normal and no ergot having been administered in the course of the labor. I was quite well satisfied that they were due to pressure upon the cord; but how, where and when that pressure was exerted, was not at that time so well settled.

Since then my observation has led me to conclude that many stillbirths are due to pressure upon a cord coiled once or more times around the neck; for in every case of stillbirth I have seen this condition of the cord existing. The shoulders are forced by each pain against the head, or the breast against the chin, more or less violently, and during the continuance of the contraction the intervening coil of cord is deprived of its circulation, and all communication between the mother and child is for the time absolutely cut off.

Recently I attended a primipara, when I am certain I should have lost the child had I not delivered with forceps. As it was I was obliged to work with the child for nearly an hour before it cried and breathed naturally. The cord was wrapped around

its neck three times, and the mother's pains were as strong as any I had ever observed, long continued and close together, but produced little if any progress. In a case like this, the forceps cannot well be employed too soon unless a stillbirth is desired, which is not infrequently the case, I am sorry to say.

In multiparæ it is quite common to find the cord wrapped around the neck of the babe without any serious results following. But in multiparæ genital passages are more roomy and relaxed, the pains not so violent and continued, and they are seldom so close together; while, as a rule, labor is ended sooner after the second stage is reached than is the case in primiparæ.

If there were any means of determining beforehand whether or not the cord was wrapped around the neck of the child in the case of primiparæ, the knowledge would constitute a strong indication for the use of the forceps, or the speedy termination of the case in some way, especially if the pains were strong, long continued, close together, and the labor protracted and slow.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, October 12, 1887.

The President, J. SOLIS COHEN, M.D., in the chair. Dr. VAN HARLINGEN read a paper on

Notes of Three Cases of Leprosy, with Presentation of One Case.

Case I.—Anæsthetic Leprosy of Mild Type. —(I am indebted to my friend, Dr. Curtin, for the opportunity of seeing this case, and of following the course of the disease for a year or more.) Señora R. was first seen by me on February 1, 1883. The patient, a native of Cuba, had only been in this country a few months, and could not speak English. She was a stout, lymphatic person, about fifty years of age. Her history, obtained with some difficulty, was essentially as follows:

She had always enjoyed good health until about a year previously, when she was suddenly attacked by vertigo and syncope, followed by a general swelling, affecting chiefly the head, arms and trunk. A little later, small macular lesions began to show themselves, at first over the forearms, and, later elsewhere. The lesions, at first brownish-

red, grew in size and became annular, leaving a dead-white condition in the centre. Usually beginning singly, the lesions coalesced as they grew larger. The patient's general health had not failed materially.

On examination, the eruption was found to affect the following regions: face, neck, shoulders, back, flexor surface of arms and legs, with some few lesions on the feet. They were macular and maculo-papular in color, most of them being raised above the skin, rather sharply defined, of a dusky reddish brown color, smooth and without scales. The smaller lesions, from a pea to finger-nail in size, were papular, raised above the skin, and sensitive to the prick of a pin. The larger lesions, from a half-dollar to hand in size, showed a depressed centre of smooth, abnormally white skin, with a brown, raised margin, giving them a ringed appearance. In some places these rings intersected each other, giving a figured or gyrate appearance. Where the skin was depressed and white it was anæsthetic to a greater or less degree. In places a needle could be thrust in half an inch or more without the patient showing any sign of pain.

The tips of the patient's ears showed some slight infiltration and thickening, and the nose was somewhat broadened; but the face had not at that time become so disfigured as to present the characteristic leonine appearance, though the surface was mottled with disease patches. The hands were rather puffy and of a deep brownish-red color, and covered with tubercular lesions. Anæsthesia existed to an extreme degree; a pin could be driven deeply into the back of the hands without causing pain. There was no change in the palm of the hand, nor any referable to a diseased condition of the ulnar nerve, although a general numbness of the finger-tips occurring at times was complained of. The feet were somewhat puffy, but no distinct disease was observed here. The eyebrows and other hairy parts seemed unchanged. There were no general symptoms, excepting languor with occasional headache. There was no history of chills and fever, or of any eruption of blebs.

The patient was at first ordered to take Fowler's arsenical solution in small doses. This was soon changed to sulphate of strychnia, of which she took one sixteenth grain thrice daily for some months, and, later, one-eighth grain nux vomica with two grains quinine four times a day. The affected parts were rubbed daily with a mixture of three parts oil of cashew with five parts oil of almonds. Under this medication the patient's general

condition improved markedly. She suffered with photophobia, however, and other eye symptoms, including the appearance of a small tubercle near the iris. At this time Dr. Harlan saw her with me. Later she suffered from some mental disorder, for which Dr. Curtin attended her. I did not see her from February, 1885, to January, 1886. She had been in Cuba in the interval, and was in a decidedly worse condition than when I saw her last. The face had begun to assume the peculiar leonine expression due to infiltration, with leprous matter at various points. The nose was markedly broadened. New superficial dusky red nodules appeared here and there, especially on left upper and lower eyelids. On the arms and forearms the white anæsthetic patches were sharply defined, and looked as if red-hot coins of various sizes had been laid upon the skin and had burned in. The left arm was the worst, and most highly anæsthetic. The hands showed the most changes. The fingers were swollen greatly, cylindrical, curved, and claw-like. Numerous tubercular elevations could be seen scattered over the backs of the hands. A lentil-sized subcutaneous nodule of gristly consistence could be felt under the skin on the back of the left wrist. The ulnar nerve could not be felt. Touch normal. The feet showed deposits similar to those on the hands. They were not, however, swollen nor markedly misshapen.

The eyes looked worse. There was considerable congestion of the conjunctiva with apparently incipient deposits of leprous matter.

Examination of oral cavity showed nothing abnormal, though her voice was hoarse.

The patient was once more placed under treatment, at first taking one-third grain extract nux vomica thrice daily, and, later, a pill of strychnia, arsenious acid, and quinine. An ointment of pyrogallac acid, at first of the strength of thirty grains, and, later, a drachm to the ounce, was prescribed. Ichthyol was also used locally, but the patient objected to the smell and use of the drug, and soon after disappeared from observation.

Case II.—Mixed Tuberculous and Anæsthetic Leprosy of Moderate Type Accompanied by Marked Eye Symptoms.—Mrs. P. M., forty years of age; born in Pennsylvania of German parentage; always enjoyed good health. Married at the age of seventeen to a native of Brazil. She lived for ten years with her husband in Philadelphia, bearing him two children, now living and healthy. In 1873, fourteen years ago, she went with her husband to Brazil, where she settled in

Para, while her husband lived in a small town six days' voyage up the Amazon. She only saw him occasionally; but, after six months, joined him, and bore a third child while there—our Case III. She returned with her husband to Para, in a year or so, and they lived there some years, the husband being captain of a steamer trading to San Antonio, at the headwaters of the Amazon, for India-rubber.

About three years ago, she and her family being at that time in good health, she made her first voyage with him up the Amazon to San Antonio. The patient stayed at this place some days, and on one occasion took dinner with a party of natives from the interior. The strange and peculiar food eaten on this occasion made the entire party sick, and our patient attributes all her subsequent misfortunes to this indiscretion. About fifteen days later, her husband was seized with the symptoms of beri-beri, and died in a few weeks.

While he was ill our patient began to observe the first symptoms of the disease, or what she supposed to be such. General nausea and loss of appetite, dizziness, and somnolence, pain in the hepatic region, swelling of the feet, and a sort of intermittent fever. These symptoms lasted for some months. Meantime other external symptoms began to show themselves. Blotches of a whitish color appeared upon the face, which disappeared, and were followed by an increase of pigment over the face and front of legs. Occasional attacks of redness and swelling of the skin, resembling erysipelas, were also observed. Blebs showed themselves on the soles of the feet, at first one or two at a time, later in crops; crusts or scales formed on the edges of the feet, especially about the heels, and dropping off left ulcers behind, which, with the blebs, healed spontaneously. The toe-nails were affected, one nail fell and was reproduced five times. Loss of hair occurred, to a considerable degree, during this period, and the patient's face became disfigured and deformed to a marked degree, so that, when she came to this country from Brazil, about two years ago, she was scarcely recognizable.

In the early part of 1886 this patient was sent to me, with her daughter, by Dr. Charles Turnbull, to whom I am indebted for the opportunity of examining and studying the case. Her condition at that time (she had been four months in Philadelphia) was much improved, but so marked and characteristic was the disfigurement that I recognized the character of the disease almost at once by

the peculiar *facies*. This presented the peculiar leonine expression so often described by authors. There were marked deposits in the eyebrows, which were thick and heavy. The tissues of the nose were much thickened, and the nose much broader. The lips were much thickened, and board-like to the touch, and were slightly everted. There had been a sore on the upper lip, but this had healed up when I first saw her, and there were no ulcerated surfaces, either at this time or subsequently. The ears were much enlarged and deformed, the lobes being particularly huge and misshapen. The eyelids were thick and infiltrated, the eyebrows and lashes mostly wanting; there was congestion of the conjunctivæ on both sides, and a small opaque patch on the upper segment of the cornea on the left side. There was brown discoloration on the shoulders and arms, with some anæsthetic patches. The hands were puffy, fingers thickened and cylindrical. The feet were in the same condition. There were not many anæsthetic patches on the lower extremities.

The patient was ordered a quarter of a grain of the extract of *nux vomica*, with a grain of quinine, three times a day. Under the use of this medicine she improved slowly, but steadily, for some time. She seemed brighter and in better spirits, her voice less hoarse, and her condition improved. Her face, however, continued to show signs of some progress in the disease. On December 3, 1886, when she had been eight or ten months under treatment, the nose was broader, especially at the alæ, and there were new deposits in the skin covering the chin. The tongue, now examined carefully, was markedly thickened, with deep fissures, and a smooth, grayish, board-like surface. It had been chapped and painful, but was now better.

During the previous month the eye-changes had become more noticeable. There was some opacity of the cornea, and several well-marked nodules of leprous tissue in the edge of the iris, and projecting into the anterior chamber of the eye. The patient could only distinguish light from darkness in this eye.

The treatment was continued until toward the close of the year. The patient declaring that she was constantly improving, but no very perceptible change being manifest, excepting that the hoarseness had disappeared, and her voice was clear, and her feet were not so swollen.

On December 22d, the patient was ordered two grains of salicylate of sodium, with three grains of potassium iodide. Within a day

or two she was attacked by high fever, with a copious eruption of petechial spots. Fearing this might be due to the medicines, both of which are known to produce such an effect, the dose was reduced one-half, under the use of which she improved.

About this time the patient was sent to St. Joseph's Hospital, where her general health improved greatly under careful nursing and attendance. Suspicion having been aroused as to the nature of the disease, she was dismissed.

Since that time she has been living with relatives, and lately has found employment in a small hotel. Her general health has improved, although she has lost flesh. The leprosy deposits about the ears and face are more marked than before, and I am inclined to think that the utmost that can be asserted is, that the patient is losing ground very slowly. She has been taking, since the beginning of the year, a solution containing one-twentieth of a grain of sulphate of stychina, with two grains of quinine, thrice daily.

Case III.—*Marked and Severe Anæsthetic Leprosy in its Earlier Stages.*—Anita M., daughter of Case II., above described, aged twelve and a half years, was seen, for the first time, a year and a half ago. No history could be obtained, excepting that the disease began about the same time as that of the mother.

Attention was first drawn to the child by the appearance of a well-marked raspberry-colored circinate eruption on her face, resembling most closely that of erythema multiforme. Only a few of the lesions were at this time decidedly anæsthetic. On stripping the child, circinate lesions could be seen over the body and limbs. These patches were whitish in the centre, slightly sunken, and surrounded by narrow brownish-red, slightly elevated borders, which had intersected at many points large gyrate figures. The patches on the lower limbs were all more or less anæsthetic, and did not seem to follow the distribution of any particular nerve, but to involve large irregular areas.

The patient was placed upon the extract of nuxvomica and quinine, and later, in addition to this, salicylate of sodium, in five-grain doses.

No very marked changes occurred during the summer of last year, but with the approach of winter the child's general condition became markedly worse. She suffered from conjunctivitis, and later from various nervous symptoms, prominent among which was an attack of temporary loss of power in the lower limbs.

The little patient's aspect began to change from this time, the lesions in the face taking on a more decided tubercular character, and her aspect being dull and stupid. The anæsthetic areas became more marked, particularly those connected with the ulnar nerves. The hands and fingers became numb, and gradually the fingers, particularly the ring and little fingers, became crooked, and nearly immobile, not showing skin, precisely the appearance known as *mains en griffe*. At one time she was seized with pains in the groins, running down the limbs, and confining her to bed several days. At another time she had rheumatoid pains in the various joints of the lower limb; and at another swelling in the left hand. There was a cardiac mitral murmur. Chorea followed these attacks in May last, for which I consulted Dr. Mills, who prescribed Fowler's solution, five minims, with four minims of extract of conium, thrice daily. Under the use of this combination the little patient's general health improved, and the choreic symptoms disappeared by the middle of August.

The disease, however, has continued to make steady progress. The nodules on the face have somewhat enlarged, and the tongue has shown signs of involvement.

The ulnar nerves on both sides can be distinctly felt from the elbow to the shoulder, rolling like large whip-cords under the skin. They are quite painful to the touch.

I have brought forward the notes of these cases with the purpose of pointing out the peculiarities of leprosy as it presents itself in the earlier and comparatively mild stages of the disease, and with the view of assisting, in some degree, in familiarizing us with its most numerous symptoms.

The matter is one of practical importance, for there is no question that the disease is on the increase in this country, and before long we may be called upon to decide what course is to be taken for the protection of the community, and, not less important, the care of the unfortunate victims of this disease.

In addition to the fact that centres of leprosy exist in Canada, in Minnesota, in Louisiana, and in California, several cases have been reported as occurring *de novo* in American soil in persons who have been born in and have never left the country.

Under these circumstances it behooves each member of the profession to ascertain and make himself familiar with the appearance of leprosy, so as to be able to recognize it at sight, and to make up his mind with regard to the contagious character of the disease, and, finally, setting aside all sentiment

and ignorant fear of the malady, to do what can be done for its removal.

I question if; at present, these patients of mine would be received by any hospital in this city were the nature of the disease known. I question if there be any refuge to which these poor lepers can resort when the time comes that those around them shall be aware of the affection from which they suffer. In the face of a disease which has, for ages, been accounted one of the most dreadful plagues, it is not surprising that uninstructed persons should be struck by blind panic. But it is the duty of our profession to instruct the public in this respect.

Leprosy is, indeed, contagious in my belief and in that of the majority of observers; but contagious in a slow and uncertain manner. Therefore we need have no such fear in approaching it as we should have in coming in contact with syphilis, much less any of the contagious exanthemata.

DR. C. S. TURNBULL, in opening the discussion, said: Dr. Van Harlingen has described the cases so carefully that very little is left to be added. With reference to the second case, it will be of interest to state that when the woman first presented herself at the Eye Department of the Dispensary of the German Hospital, we were led to believe, from the appearance of the eye, that she was suffering from syphilitic iritis. The primary affection began in the iris. There were pain and plastic exudation, and the other symptoms usually complained of. The disease, however, failed to yield to specific treatment. Subsequently nodes appeared upon the conjunctiva of the left eye, and later one commenced to form upon the cornea, closely resembling a case of (Arlt's) lymphatic keratitis, and finally involved the entire cornea. About last December the centre of the anæsthetic nodule began to break down, and we believed that the eye was about to perforate. This, however, did not occur. The opening closing over, and the eye remaining in about the same condition in which it is at present, with the exception that every portion of the cornea has become involved, and is now one anæsthetic leprous nodule. Having once started in an eye, this affection is slowly but surely fatal to the sight. A suspicious spot is seen on the conjunctiva of the fellow eye, and we fear that if the affection starts in the cornea of that eye the woman will soon be completely blind.

DR. J. W. HOLLAND said: I regret that I have no personal experience to communicate. In the interior, where I resided for

years, leprosy was practically unknown. In Minnesota, where the disease is epidemic, I fancy that it has been brought there by the Norwegian immigrants, who are very numerous in that State. The same is probably true of Canada. I believe that, as a rule, the distribution is largely on the sea-boards. I have seen the disease in New Orleans some four years ago. I saw a case in the Charity Hospital of that city in the later stages of ulceration. The pain was so severe that the patient had to be kept under the influence of morphia. The physicians did not consider the disease contagious, and they have had considerable experience with it. At one time there was a leper hospital in the vicinity of the city, but at present the cases are treated in the ordinary hospital in wards with other patients. At the same time there were in the out-patient department two children suffering with the same disease, and the affection was supposed to be due to the character of the food. It was thought that the eating of stale fish had something to do with it. This idea was not based upon any research into the constitution of the food, but rather from the fact that the persons affected with this disease lived, as a rule, a maritime life, and, being in the lower walks of life, had to take what food they could get. It was also recognized that the disease might be inherited.

DR. H. W. STELWAGON said: I hesitate to express a positive opinion regarding a disease which I have seen so little clinically. Various views of the etiology of the disease have been held from time to time, and even at the present time these differences prevail. It was formerly charged to dietary and climatic influences, but these, as exclusive factors, have been disproven. Another view holds that its spread is due entirely to hereditary transmission, but a study of the affection has excluded this as a main etiological cause. Later opinions are that the disease is contagious through inoculation, a view that has much in its favor, but this also has been disputed by some writers who have been in position to study the disease. One fact that appears to be against this view is, that in Norway, where there are from two to three thousand lepers, the number of cases has been steadily decreasing for the last fifteen or twenty years. This decrease is due, it is true, in a measure to the establishment of lazarettos, but not entirely so, for these contain not more than one-third of the whole number of lepers. At the present day, therefore, more or less doubt still exists as to the nature of this disease.

DR. W. OSLER said: The questions with reference to the contagiousness or inheritance of leprosy are, of course, exceedingly interesting. Dr. Graham, of Toronto, has made an elaborate study of the disease as it occurs at Tracadie, New Brunswick, and has come to the conclusion that the disease is contagious, and that it is not transmitted by inheritance. There, as in Norway, the cases have been progressively diminishing in number. Certainly, if contagious, it must be so in a very slight degree. It is probably not nearly so contagious as ordinary tuberculosis.

I would ask Dr. Van Harlingen, whether he has made any examination of sections of the skin in the second case? We may, however, take it for granted that bacilli are present.

I have had few opportunities for seeing leprosy. A case of interest, which came under my observation in Canada, was that of a man occupying a prominent position in one of the religious denominations, who had suffered for some thirty years with the anæsthetic variety, and whose sight was finally destroyed by leprosy keratitis.

DR. A. HEWSON said: I should like to make a few remarks with reference to the treatment of this anæsthetic form of leprosy. I have seen something of it, and recently resorted to a plan of treatment which I may say was suggested to me by the lecture of the President of the Society on Bergeon's use of gas, as in the treatment of phthisis. I resorted to this expedient in a case where the bacilli were recognized in the skin. I applied the mixture of gases to various parts of the skin, especially the lobes of the ears, by means of inverted funnels, for twenty minutes each day. There was a perceptible reduction in the induration in the course of twenty-four hours, and at the end of ten or twelve days there was such an improvement that one would hardly have recognized him as the same patient.

I may say in this connection, that I have been treating cases of keratitis with granular lids by means of these applications of the sulphuretted hydrogen and carbonic acid gases together. Within twenty-four hours there is such a reduction in the swelling and induration that the lids, which before could not be everted, can be examined without difficulty, and the presence of granular lids as the cause of the keratitis demonstrated. The application in all such cases proves acceptable to the patient by its characteristic sensation of gentle warmth to be felt in the part.

DR. VAN HARLINGEN said: My object, to-night, was simply to exhibit this case of leprosy, and not to read a paper on the disease; I have, therefore, not referred to certain of the points brought out in the discussion. I have not yet made such examinations as Dr. Osler has suggested, but I shall be glad to do so. My main reason for not making sections was, that I did not wish to run the risk of producing lesions that might give the woman trouble. I see, to-night, that she has cut her hand severely. If these wounds heal kindly, I shall be tempted to remove a piece of the diseased skin for microscopical examination.

The treatment has been referred to. It may be said that as the cause of the disease lies in bacillar infection, anything that will kill the bacilli will probably benefit the patient. Dr. Unna, of Hamburg, from a study of certain cases, has come to the conclusion that a great deal of benefit is to be obtained by the application of certain agents which kill the bacilli. How far this method will prove effective I do not know. That it will prove effective in the anæsthetic form I very much doubt. The reason that a patient has anæsthetic patches is not that the bacilli are in the skin, but that they are deposited in the nerves which supply these patches.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, October 24, 1887.

The President, Laurence Johnson, M.D., in the chair.

Dr. Johnson was re-elected President; Dr. L. Bolton Bangs was elected Vice-President; Dr. Carpenter, Secretary; Dr. Alexander Hunter, Treasurer. Five Censors were also elected—Drs. Daniel Lewis, J. S. Warren, R. Van Santvoord, W. E. Bullard, and William Stevens. Dr. Charles H. Avery was re-elected Assistant Secretary.

Dr. O. B. Douglas, having filled the office of Treasurer for eight years, had declined a renomination. He read an interesting review of the work of the treasurers of the society since its foundation, eighty-two years ago.

Dr. John C. Peters had been appointed by the Committee of Hygiene to investigate with regard to cholera at quarantine, brought on the steamer Alesia. He had made but one visit to the two islands, and on that occasion he found everything in a very cleanly condition, and at Swinburne Island, where those sick with the disease occupied pavilions, everything was in perfect order. The

immigrants not affected were kept on Hoffman Island, on which were three buildings, clean but dingy. They were divided into three classes, according to their degree of neatness. Among the dirtiest class only had the disease spread; one case had occurred among the second-class. The food was good and well cooked. The immigrants had to eat many of them from a common vessel, without knife or fork, employing their fingers.

The class among whom the disease had spread were dirty, and appeared to have wiped their hands on their clothes after eating. There was no water in the wash-basins in the room; he forgot to inquire as to the facilities for bathing and washing the hands and face. Putting the hands into a common dish at dinner would be an efficient mode for spreading the disease. He was told it was the custom of steamship officers not to give Italians knives and forks with which to

eat, through fear they might use them as weapons.

New Yorkers had let an important opportunity pass for a thorough study and investigation of cholera which had not appeared at this port for twenty years, and the Philadelphians had come over to reap the reward. He understood the report of the committee from Philadelphia would contain a less favorable statement regarding the condition of the buildings at that time. There was no resident physician on either of the islands. He was unable to say exactly where the responsibility rested for any faulty condition of the institutions, but according to law appropriations should be made by the Legislature for keeping them in order. The income from the quarantine department was amply sufficient, he understood, for this purpose, if it were not used for election purposes, as it was commonly believed to be.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Chronic Diphtheria.

Dr. Luigi Concetti, of Rome, Italy, gives the following account of this case: In a Roman family in good circumstances, the five-year old son, Umberto, was taken sick about the middle of November, 1885, with a serous and occasionally bloody discharge from the nose. This child, like the other children of the family, was of lymphatic temperament, but had enjoyed good health, with the exception of a slight malarial affection in his third year, which quinine cured, and some other slight ailments.

This discharge from the nose was not accompanied with the symptoms of ordinary catarrh, though the parts adjacent to the nostrils were red, and on the right side of the septum was seen, firmly adherent to the swollen mucous membrane, a grayish-white film. The affection received no further attention until December 13th, when fever of a remitting type, varying from 99° to 104°, appeared. This attack continued for eight or ten days, was treated as a catarrh of the stomach, and was not thought to be connected with the nasal affection. As the fever lessened the discharge from the nose increased. Ulcerations appeared, which were covered with a grayish-white, firmly adherent film, and with yellow crusts. Washings with

a weak solution of salt and water had no effect in changing the condition; the tongue was slightly coated at its base, and the throat was normal. On January 10th, fever reappeared for three days. On January 13th, an older child in the same family was taken sick with a severe attack of the ordinary anginal diphtheria, and recovered after an illness of eight days. On January 15th, a younger brother, fourteen months old, likewise fell ill of diphtheria, and died on the second day; and on the very same day the maid servant had a slight attack. On January 17th, a little sister, three years old, was taken sick in the same way as her elder brother.

Umberto still continued to have the discharge from his nose, which was now treated with borax and salicylic acid, and, though this did not improve the local disease, the fever subsided and the general condition became considerably better.

No diphtheritic membrane was ever noticed in the throat. About the middle of February the voice became nasal; on the 23d, swallowing became difficult, and fluids that were taken often passed out through the nose; subsequently, these symptoms became still more decided. After a few days, both the children developed diphtheritic paralysis, the latter lasting in Umberto's case six weeks. As it gradually grew better, the false membrane in the nose and also the discharge, disappeared. The whole duration of the nasal affection was four months.

That it was really diphtheria is proved by the fact that characteristic false membrane persisted for four months; that fever was not present at the beginning of the local affection, and that no other febrile process could have been concerned; that this fever arose from the absorption of products formed in the nose. Besides, there are no other nasal affections which produce the peculiar paralysis observed after diphtheria. The incubation period of diphtheria occupies, as we know, from six to ten days or more; therefore the four other cases of diphtheria in the same family, whose symptoms were classic, must have had a common source of infection, as only three days separated the beginning of the first case from the beginning of the last; and though diphtheria is at times prevalent in Rome, the fact that the others were in intimate contact with Umberto is first to be considered.

The author gives a review of the literature of cases of chronic diphtheria and finds that most of the others began in an ordinary acute attack, whereas this one was chronic from the beginning, and only interrupted by two short febrile periods, which the author attributed to absorption of the decomposed discharge from the nose—*Deutsche Medizinisch-Zeitung*, September 1, 1887.

Salicylic Acid in Food and Drink.

The effect of this acid upon health has been thoroughly investigated in France, and its use in foods and drinks has been prohibited in that country since 1881. Prof. E. H. Bartley, of the Long Island College Hospital, Brooklyn, has recently examined this question with great care, and in an article which appears in the *American Analyst* his views and those of other authorities are given in full. In the use of this acid in the treatment of rheumatism, clinical observation shows that it cannot be continued for a long period of time without impairing digestion, and in its elimination it passes out undecomposed through the kidneys. It has been recognized that under these circumstances it not only irritates but inflames these organs. In preserved food we have to do with smaller quantities of the acid, as a rule; though that this is not always the case is shown by Professor Bartley's figures. He says, "The quantity of salicylic acid usually employed in wines is from six to eight grains per gallon, and in beer from twelve to fifteen grains per gallon; or, in the case of beer, from one to one and a half grains to the glass. As many men habitually drink twenty-five glasses

during the day, they take from twenty-five to thirty-seven grains of the acid per day. The medicinal dose is usually stated to be from ten to twenty grains." He also calls attention to the fact that nursing mothers are frequently recommended to drink ale, porter, or beer, with the idea that it stimulates the mammary gland, and mentions the additional fact that temporary renal disease is frequent during the first weeks of lactation. In conclusion, Professor Bartley says, "I should state that another serious objection to the use of salicylic acid is the fact that many samples found in the market contain more or less carbolic acid. It is now almost entirely manufactured from this very poisonous substance, and, unless great care is exercised, an appreciable amount of it is left in the finished product. Indeed, some writers think that some of the fatal accidents recorded from the use of salicylic acid have been due to the presence in it of carbolic acid. If the use of this acid is to be countenanced, impure articles will be used, and greater damage may be done than could come from the pure article. From a careful consideration of the whole subject, I am compelled to regard the use of salicylic acid in foods and drinks, and, especially in lager beer, as at least open to serious objections. If it be harmless to healthy adults, the evidence of its deleterious action upon the aged and certain other classes of the community is too strong to be disregarded by sanitary authorities, and should prohibit its use for this purpose."—*Science*, Oct. 7, 1887.

A Case of Hypospadias in the Female; Operation; Cure.

Dr. A. Rabagliati reports the following case in the *British Medical Journal*, September 17, 1887:

E. D., aged 24, was admitted an in-patient of the Bradford Infirmary on September 24, 1886, and remained in until October 28. She complained of incontinence of urine, saying that she had not proper control over the bladder, and that the urine dribbled from her more or less constantly; but that the dribbling was worse at some times than at others. This condition had lasted for some years, but was getting worse of late. During her stay in hospital an emplastrum cantharidis was applied to the nape of the neck, and she was treated by the internal administration of belladonna, bicarbonate of potash, bromide of potassium, henbane, iron and other remedies. The blister to the nape of the neck seemed undoubtedly to relieve her, and

after five weeks she left hospital somewhat improved. The relief, however, was not permanent, and in March, 1887, she again became an in-patient of the infirmary. The medical measures being inefficient, an examination of the parts was made. When a Sim's speculum was passed into the vagina the upper surface of the urethra was seen for half an inch. It was red and prolapsed. Patient had seemingly no control over the flow of urine, as it came away in gushes while the speculum was in the vagina. After the menstrual period was over, on May 4, the patient was put under ether, when a catheter was passed into the bladder, and the margins of the urethra pared on the under surface. The mucous membrane was then brought into apposition, edge to edge, with chromic gut sutures, and the vaginal surface also brought together. On May 8, the patient was found to be able to retain her urine and control her bladder. On the 12th, an aperient was administered. The urethra was found to be lengthened by half an inch. On the 16th the last stitch was removed, and on May 24th the patient left hospital with full control over her bladder. When seen a month later she was quite well.

This case is interesting because it was found that the cause of the discomfort was one which could be remedied by surgical interference. Many cases of what is vaguely called incontinence of urine are very troublesome, although most, being found in children, usually improve as development progresses. The cause here was deficiency of the inferior wall of the urethra, a condition which I have not before seen in the female, but which, under the name of hypospadias, is not so uncommon in the male. The deficiency may be of many degrees, from the slightest want of approximation of the two halves of the urethra inferiorly and anteriorly, as in this case, to complete deficiency of the floor of the urethra, from failure of the two halves of what corresponds with the corpus spongiosum urethræ in the male to unite. The moral of this case obviously is that in all cases of incontinence a physical examination ought to be made to determine the exact condition of parts, and whether, therefore, any surgical help can be given to the patient, or not.

Parotitis after Ovariectomy.

Dr. E. Bumm, in a communication to the *Münchener med. Wochenschrift*, No. 10, 1887, says that after ovariectomy there sometimes occurs an inflammation of the parotid gland, which pretty frequently leads to suppura-

tion. He has found seventeen cases of parotitis of this kind. It cannot be explained as a coincidence, nor can it be referred to pyæmia. Bumm found in the sero purulent secretion the staphylococcus aureus.

In explaining this symptom, the author refers to the well known connection between the sexual organs and the parotid glands. He is disposed to think that nervous paths exist between both, which permit a reciprocal transference of irritations. In this way, perhaps, an irritation which affects the ovary, produces a vaso-motor disturbance in the parotid, which increases up to simple inflammation. If, while in this condition, pus-forming bacteria, which are perchance in the mouth, should wander into the salivary glands, the inflammation may result in suppuration. — *Deutsche Medizinical-Zeitung*, September 29, 1887.

Dislocation of the Scapula.

Dr. W. E. Home, Surgeon to H. M. S. *Alexandra*, reports the following case in the *British Medical Journal*, October 8, 1887:

A seaman, when on leave in Valletta, on July 1st, 1886, slipped on a piece of orange peel and fell, striking the back of his left shoulder against the curbstone. On rising he felt pain in and about the shoulder, so much increased by movement that he came off at once to the ship. When I saw him, half an hour after the accident, he was sitting stripped to the waist, and leaning forward so as to support the left elbow on the knee. The anterior axillary fold was lower on the left side than on the right, and the girth round the shoulder through the axilla was also greater on this side than on the other by an inch. The left clavicle was the same length as the right, and, like the left acromion, was smooth in outline and continuous with itself all round; however, between the clavicle and acromion was a deep groove in which the finger could be laid. The scapula had been displaced downwards, outwards and forwards, the tip of the coracoid being an inch and a quarter below and a little to the inner side of the outer end of the clavicle. On pressing the clavicle down and the shoulder upwards and backwards, the pain (felt along the insertion of the trapezius chiefly) was relieved, and the normal appearance of the shoulder was restored. To retain the parts in position, the outer end of the clavicle was fixed by a piece of strapping (4 inches by 15 inches) passed over it, another strap, folded round the middle third of the arm and drawn tightly across the back, steadied the arm and shoul-

der, while the elbow was brought forward and pressed upward by a flannel roller, passing round the body and over the right shoulder. The patient was then laid on his back in bed. On July 9th the strapping was reapplied; and on the 17th he was allowed to get up. The strapping was removed on the 22d (three weeks after the accident), and he was discharged to duty, well, on the 24th.

Seen again on August 21st, 1887, fourteen months after the accident, he declared that the arm was as strong as ever, and that it gave him no inconvenience. The outer end of the clavicle was somewhat thickened; but the relations of the clavicle to the coracoid, acromion and scapula generally, were quite normal, and were so maintained during movements, which were all perfectly performed.

The primary treatment was Sayre's for fractured clavicle; but I believe that the fortnight's rest in bed had nearly as much to do with the successful result.

A Case of Rupture of the Diaphragm and Dislocation of the Thoracic Viscera.

Mary S., twenty years old, while engaged in digging sand in a sand-pit on December 1, 1886, was called to by some of her female friends, and looked around; at the same instant she fell upon her back, and a mass of sand was suddenly precipitated upon the lower part of her body, especially over the abdomen, while the upper part of her body remained entirely free. Help was at hand, and she was quickly drawn out and put to bed.

An hour after the injury happened, Oscar Kirschen, who reports the case, reached the unfortunate woman, and found her entirely conscious, but complaining of horrible pain in the abdomen. She was exceedingly pale, with a small, scarcely perceptible pulse, so that Kirschen at once thought there must be internal hemorrhage, and gave her a hypodermic injection of ergotin. But when he removed the bed-clothing from his patient, he discovered an enormous quantity of blood, which proceeded from a linear tear with ragged edges, including skin, subcutaneous tissues and the muscles, and extending on the right side from the mons veneris through the clitoris into the vagina, and posteriorly just to the anus. The hemorrhage had already ceased of itself, and when a closer examination was begun, the condition of the patient all at once changed; she became suddenly very cyanotic, screamed, called for water, and constantly tried to get out of bed, so that she had to be held. Finally, she became

completely unconscious, her pulse became quick, and she died quietly three hours after the injury.

On the 3d of December, two days after the injury, an autopsy was held, which disclosed, the following interesting results: The stomach, with its greater curvature looking anteriorly, occupied the normal site of the heart; next this, occupying the entire space usually filled by the left lung, was the large intestine and a great part of the small intestine; beneath this coil was found the spleen. The left lung was completely raised from the posterior thoracic wall and placed over the anterior surface of the stomach, which, as has been stated, occupied the normal site of the heart. The heart had been pressed over into the right side of the chest, and was completely covered by the right lung. The left lobe of the liver projected in like manner into the left thoracic space. Inspection of the diaphragm disclosed a complete rupture of its tendinous part, the tear extending also to several places in the muscular part. In spite of this extensive injury both in the belly and in the chest, there was no effusion of blood. This latter phenomenon is accounted for by the author in part by the fact that the injury through the clitoris had allowed such an enormous quantity of blood to escape, and in part by fact that the pressure of the mass of sand had prevented any entrance of blood into the abdominal and thoracic cavities.—*Wiener Med. Presse*, No. 35, 1887.

Eucalyptus in Whooping-Cough and in Bronchitis.

Witthauer (*Memorabilien*, Sept. 3, 1887) strongly recommends the administration of eucalyptus for whooping-cough and bronchitis. In whooping-cough, he gives from five to twenty drops of a mixture of equal parts of tincture of eucalyptus and glycerine, according to the age of the child, every three hours. He also administers inhalations as follows: A piece of linen is made into a bag, in which is placed a piece of cotton on which ten drops of oil of eucalyptus is put every morning. The bag is tied around the neck of the child so as to be under the shirt, and so the child is in an atmosphere of eucalyptus by day and by night.

In bronchitis, Witthauer gives to an adult from fifteen to twenty drops of the tincture of eucalyptus every three hours. Inhalations are given by placing ten drops of the oil in a cup of hot water, and causing the steam to be inhaled.—*Allg. Med. Central-Zeitung*, Sept. 10, 1887.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

ON THE ACT OF CONCEPTION.

At the present time but little is known positively about the manner in which the spermatozoa are brought into such a contact with the ovule as is favorable to conception. Little reliance can be placed upon the theory that they find their way into the uterus or Fallopian tube by means of their own power of locomotion. On the contrary, it seems most likely that they are transported thither by influences external to themselves. These influences depend chiefly upon the functional activity of the female sexual apparatus: the vagina, uterus and tubes, all of which are organs the shape and consistency of which alter under varying circumstances. The fortunately rare occurrence of tubal or abdominal pregnancy probably depends upon the possibility that the Fallopian tubes may alternately draw and propel the sper-

matozoa until they reach some point within them, or even are expelled from the orifice at their free extremity. But before this can occur the spermatozoa must enter the uterus; and the question how the latter may take place must take precedence of any question in regard to the former occurrence.

We have not space to discuss many of the theories as to how the spermatozoa enter the uterus, but will present what seems to us to be the most rational one. In 1872, Dr. BECK, in an able article cited in this journal (MEDICAL AND SURGICAL REPORTER, October 12, 1872, pp. 340, 341), described certain observations made upon a prolapsed uterus. These observations and others led WERNICH (*Berliner klin. Wochenschrift*, March 3, 1873) to describe the act of entrance as follows: As erection takes place in the penis in man, so a preliminary erection of the vaginal portion of the uterus—and of this alone—takes place in the woman at the period of most intense orgasm, and almost simultaneously with ejaculation on the part of both individuals, the cervix becomes relaxed and soft again, and the os uteri opens. With this comparatively sudden relaxation of the erected condition, which is made possible by a peculiar arrangement of the blood vessels, a series of gasping or sucking movement of the cervix takes place, during which the os is retracted, and the semen is aspirated into the womb.

This theory seems to harmonize with many facts with which students of the subject are familiar. The female is rarely absolutely passive in the act of coitus. Even those women who have little inclination, or even a moderate repugnance to the act itself, yield involuntarily to the reflex stimulation which it occasions, and their sexual organs respond, though their will may not. Further, there are times when this response is more favorable to conception than others. The more active the participation of the female, the more likely is it that the share in the act of conception which nature intended for her shall be performed. And this participation is apt to be most active when her instincts are normally developed

and normally brought into play. When circumstances occur inimical to her full and willing participation, her share in the work of propagation is unlikely to be performed.

Equally true is it that the act of coitus, to be most favorable to conception, must be marked by simultaneous culmination of the orgasm. When the man and the woman reach this point at different times, especially when the woman reaches it first, the spermatic fluid may remain as a foreign body in the vagina, to be afterwards expelled by the natural contraction of this canal.

The habit of intercourse which is established in the married state sometimes leads to frequent conception, and sometimes to infrequent conception, depending upon the times at which the act is performed. If these are the times when the wife is most likely to participate unreservedly, and, when the menstrual function is not likely to imperil conception, conception will occur often. If times are chosen when the wife is less subject to reflex excitement, or when the monthly molimen will shortly sweep out the contents of the uterus, conception will not occur so frequently.

Thus, conception is seen to depend largely upon mechanical conditions inherent in the female sexual apparatus, regulated by influences partly psychical and partly physical. The share of the female in the event is by no means passive, and its occurrence may be regulated by a line of conduct based upon a judicious observance of the facts to which we have called attention.

Of this subject we shall speak at another time; for we believe that a proper understanding of it, and a chaste utilization of its suggestions, would remove some of the hardships to which many married women, and some married men, are subjected, as has been declared by certain of our correspondents upon the "Conjugal Question."

We do not hesitate to bring before our readers the consideration of this very important subject, and of those with which it is allied; because we feel convinced that they need discussion, in the interests of humanity and of civilization.

MORPHINOMANIA.

Dr. Seymour J. Sharkey has a very interesting article on morphinomania in the *Nineteenth Century*, September, 1887, in which we think he takes a somewhat exaggerated view of the extent of this evil, founded upon a too implicit acceptance of the statements of men who, because they have made a study of the subject, have been brought into contact with a disproportionate number of its victims. There can be no doubt that every large city contains a certain number of persons who have yielded to the subtle influence of the morphia habit; but we believe this number to be absolutely and relatively small. When one thinks of the enormous quantities of morphia which are administered by medical men, and the too loose way in which physicians sometimes authorize their patients to take morphia by the mouth or hypodermically, the wonder is that there are not more morphinomaniacs.

At the same time, one such unhappy creature would be too many. and it is a duty which becomes daily more pressing that medical men, appreciating the horrors of the morphia habit, and the almost equal horrors of the attempt to escape from it, should exercise the greatest prudence in the administration of opiates, and the severest caution in suggesting self-administration of morphia to their patients.

For a fair presentation of the horrors alluded to, we can refer our readers to the article of Dr. Sharkey. For the prudence and caution which we believe to be important, we can only refer them to their own good judgment. The use of morphia, at proper times, is one of the greatest boons which suffering humanity has ever enjoyed; its misuse may become one of the greatest curses with which mankind can be afflicted.

IODOFORM AS A GERMICIDE.

About a year ago Heyn and Rovsing, two physicians of Copenhagen, startled the surgical world by announcing that they had made a series of experiments which proved that iodoform had no real power as a germicide, and that, in fact, certain bacteria would thrive in iodoform. This announce-

ment was so inconsistent with surgical experience that it led to new investigations, which demonstrated anew the interesting and important fact that it is unsafe to generalize from the action of a remedy in chemical, or artificial physiological, apparatus as to what it will do in the tissues of the living body. It was soon found that, however iodoform might behave in test tubes and experiment flasks, it did protect against the action of disease germs when applied to wounds or diseased surfaces. This effect is due, as De Ruyter, of Berlin, has shown, partly to the mechanical obstruction (filtration) which it afforded to the entrance of germs from without, and partly to the fact that, when in contact with the fluids of the body, it is decomposed and free iodine is liberated, which is a potent germicide. If iodoform is dissolved in ether, or in ether and alcohol, it is decomposed by the action of sunlight. Further, when such a solution is added to water, iodine is liberated and mingles with the water.

These experiments establish the value of iodoform as a dressing for wounds, and confirm the results of innumerable clinical experiences. So that surgeons may rationally continue the employment of this agent, and expect it to serve in the future as in the past, as one of the most valuable aids to aseptic surgery.

SACCHARINE.

In the *Allg. Med. Central-Zeitung*, September 17, 1887, Dr. Th. Clemens describes the nature and uses in medicine of this newly discovered substance. Saccharin was first isolated from petroleum by Dr. Fahlberg, of New York. Chemically, it is benzoyl sulphonic imide; a white powder, easily soluble in alcohol and hot water, and less so in cold water. One part in 70,000 parts of water makes the latter taste sweet, and it has 300 times the sweetening power of cane-sugar. It can be used instead of the latter by patients with diabetes. It has also very great antiseptic power. According to Aducco and Mosso, if urine is mixed in equal parts: 1st, with a 0.32 per cent. solution of

saccharine, 2nd, with a 0.32 per cent. solution of salicylic acid, and 3rd, with distilled water, after seven days no alkaline fermentation will have occurred in the first mixture, while it will have begun in the second, and have gone very far in the third. Similar results have been obtained in experiments with a pancreas-emulsion.

For internal administration, saccharine, which is an acid, must be given with soda. In Germany, tablets are prepared made up of saccharine, about $\frac{1}{8}$ gr., bicarbonate of soda $\frac{1}{3}$ gr., and mannite $2\frac{1}{2}$ grs. Saccharine is harmless when given internally, but Clemens believes it acts on the salivary glands and hinders the reduction of starches into glucose. He has also used it with advantage in two cases of ammoniacal urine. He thinks it a valuable agent in the treatment of fermentative processes in the stomach and intestines, and that it is superior to boric acid or salicylic acid in this respect.

THE JEFFERSON MEDICAL COLLEGE.

We observe with regret that there appears to be a concerted attempt, on the part of certain medical men in this city, to create bad feeling against the Jefferson Medical College. There seems, also, to be some ground for believing that this effort is made with the expectation that it will indirectly benefit a rival institution. If this be a fact, we think it is time for the alumni of the Jefferson Medical College all over the country to recognize it and to exert themselves, in order that any hopes founded upon such a course of conduct shall not be too easily satisfied. Loyalty to their Alma Mater should, we believe, prompt them to meet this peculiar exigency with courage and firmness. In so doing they will have the approval and good wishes of all men who think that fidelity is something more than a name.

—The *Deutsche Med. Wochenschrift*, Oct. 6, 1887, announces the death of three distinguished medical men: Dr. Friedländer and Dr. Hirschfeld, in Breslau, and Dr. Wecker, in Frankfurt-on-the-Main.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the *REPORTER*.]

LESSONS IN GYNECOLOGY. By WILLIAM GOODELL, A.M., M.D., Professor of Clinical Gynecology in the University of Pennsylvania, etc. Third edition, thoroughly revised and greatly enlarged. 8vo, pp. xiv, 579. Philadelphia: D. G. Brinton, 1887. Price, \$5.00.

This third edition of a book already well-known has all the characteristics which made those that went before so successful. The author's wide experience in practicing and in teaching the healing art, as applied to the diseases peculiar to women, make him more fit than most men for preparing such a book. His writings are therefore always welcome, and enhance the reputation which he has gained in the clinic and in private practice. His literary style is peculiarly charming. There is a directness and simplicity about it which it is easier to admire than to copy. His choice of plain words and almost blunt expressions, his familiar comparisons and homely illustrations, make his writings, like his lectures, unusually entertaining. The substance of his teachings we regard as equally excellent, but their acceptance will rest more upon his reputation than upon anything which we may say about them. If we were to criticize, we would suggest that the author is too strongly impressed with the necessity for certain details of the so-called antiseptic method. When he recommends "Strict Listerism" in certain surgical operations, we believe he has too good an opinion of this method, which has been abandoned as dangerous by some of the most successful operators in general and special surgery. And when he says: "In every case of labor, the vagina should be syringed out with a quart of 1:2000 solution of corrosive sublimate, both as soon as the os has fairly dilated, and directly after complete delivery," we believe that thousands of our readers will feel that he insists upon a needless, as well as a troublesome precaution.

But these are matters of opinion. As a whole, we can heartily recommend this book, which contains so much wholesome instruction that it can hardly be spared from any physician's library.

DIFFERENTIAL DIAGNOSIS. By F. DE HAVILLAND HALL, M.D., etc. Third American edition. Edited by Frank Woodbury, M.D., etc. 8vo, pp. xii, 255. Philadelphia: D. G. Brinton, 1887. Price, \$2.00.

Dr. Hall's manual on "Differential Diagnosis" is made up of brief descriptions of different diseases, and a comparison, in parallel columns, between each one and others with which it might be confounded. In the main, it is an excellent work, and a good guide to those to whom it is addressed. We observe certain omissions; as, for example, the statement that trichinosis may be mistaken for rheumatism, when speaking of the latter disease; and the questionable assertion, when discussing trichinosis, that "the differential diagnosis from rheumatism is in the soreness being in the muscles and not in the joints." We agree with the author (or editor?) that "the diagnosis of hydrocephalus may be confirmed by tapping the fontanelle with the aspirator, or a hypodermic syringe;" but we would not advise our readers to adopt this means of confirming their diagnosis.

We would be glad to know that Dr. Hall's book was published in this country with due regard to the moral rights of its author. We trust it is not an example of that modified form of literary piracy which has been too prevalent on both sides of the Atlantic Ocean.

FUNCTIONAL NERVOUS DISEASES; THEIR CAUSES AND THEIR TREATMENT. Memoir for the Concourse of 1881-1883. Académie Royale de Médecine de Belgique. With a Supplement on the Anomalies of Refraction, Accommodation, etc. By GEORGE T. STEVENS, M.D., PH.D., etc. 8vo, pp. xiii, 217. New York: D. Appleton & Company, 1887. Price, \$2.50. From P. Blakiston, Son & Company, Philadelphia.

This work is a translation of the essay which received the highest honor awarded by the Royal Academy of Medicine of Belgium for the competition of 1881-1883. It is the result of a study of twenty-six hundred and ninety-two cases of nervous disease in private practice and of a considerable number in public institutions. The conclusion of the author is that difficulties of accommodation, and of adjusting the eye for vision, or irritations of the nerve involved in these processes, are among the most prolific causes of nervous disturbance, and more frequently than other conditions constitute a neuropathic tendency.

In discussing this thesis, the author adduces a very convincing array of cases in which persistent headache, neuralgia, spinal irritation, neurasthenia, chorea, epilepsy, and even insanity, were cured by correction of disorders of the muscles of accommodation or of adjustment of the eyes. He also gives an interesting exposition of the way in which deficiencies of these muscles, being propagated, lead to a hereditary tendency in certain families to the development of nervous disorders. His argument is illustrated by beautiful reproductions of photographs, which show the appearance of patients before and after the eyes had been treated, and which strongly support the views he expresses.

We heartily commend his book to all thoughtful students of nervous diseases, feeling sure that they cannot fail of finding in it most valuable suggestions.

ARTIFICIAL LIMBS, AND THE AMPUTATIONS WHICH AFFORD THE MOST APPROPRIATE STUMPS. By HEATHER BIGG, Assoc. Inst., C. F., L.R.C.P., etc. 8vo, pp. vi, 128. London: published by the author.

Mr. Bigg has had unusual opportunities to study the question of the forms of amputation which are best adapted to the subsequent use of artificial limbs, and the results of his study are embodied in this book. He demonstrates that the best forms of amputation are not always those which would be suggested by the natural desire to save as much of a limb as possible; but that one should rather choose those which promise the greatest usefulness attainable under the circumstances. The book is illustrated with a large number of cuts, which add much to its worth.

TRANSACTIONS OF THE TEXAS STATE MEDICAL ASSOCIATION, NINETEENTH ANNUAL SESSION, 1887.

There is a breeziness about the report of the business and general transactions of the Texas Medical Association, which makes the first part of this volume very interesting reading. The gentlemen who make up the Society seem to be given to speaking their

minds with great plainness, and not to fear having what they say put into print. Questions in regard to breaches of the Code of Ethics are handled without gloves, and the interests of the medical profession are defended with great vigor.

The scientific part of the volume is also very interesting. The subjects discussed are of the most varied character, and they are handled in an excellent manner. One of the more interesting of the papers is that of Dr. Thomas Wooten on the University of Texas, in which a strong plea is made for the establishment of a Medical Department in it. With this object, we feel a hearty sympathy, and hope that the great State of Texas may soon have what its extent and resources seem to demand.

MARYLAND STATE BOARD OF HEALTH, 1887. The Sanitation of Cities and Towns and the Agricultural Utilization of Excretal Matters. Report on Improved Methods of Sewage Disposal and Water Supplies. By C. W. CHANCELLOR, M.D., Secretary, etc.

This is an admirable report, containing much which is interesting to students of public hygiene. The author describes a plan and apparatus of his own invention for disposing of excreta, a patent for which has been applied for. This plan consists essentially in permitting the excreta to fall into an air-and water-tight compartment below the level of a filtering arrangement, through which the water and soluble ingredients pass up to a higher level. From this, they pass over to a second compartment containing another filtering arrangement, through which they are filtered downward. In this way the solid parts are detained in the first receptacle, and the last contains only a liquid, which has been, by mechanical and chemical means, rendered comparatively pure. For further details of the apparatus we must refer our readers to the Report itself.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—We have received the first number of the *Annals of Gynecology*, a monthly journal edited by E. W. Cushing, M.D., of Boston, and published by Rockwell & Churchill. Price, \$1.00 the first year, and after that, \$2.00. The initial number, dated October, 1887, contains several interesting articles, and is handsomely illustrated.

—*Lea Brothers & Co.* announce a new edition of Gray's Anatomy, edited by Dr. W. W. Keen, with corrections and additions to the text and over a hundred new illustrations. A part of this edition will contain colored illustrations; in a part, the illustrations will be printed only in black, as heretofore. The colored edition will be ready in November, and will cost \$1.25 a copy more than the uncolored one.

—*Seidel's Industrial Instruction*, translated by Miss Margaret K. Smith, of Oswego (N. Y.) Normal School, is to be published by D. C. Heath & Co. in a few days. This book presents the principles underlying the claims of hand labor to a place on the school programme. Persons interested in the present discussions concerning industrial education will feel an interest in this timely addition to the literature on the subject.

CORRESPONDENCE.

Priapism in Leukæmia.

EDS. MED. AND SURG. REPORTER :

Sirs:—Dr. Ady's case of priapism in enlargement of the spleen illustrates a curious symptom which has been observed in seven or eight cases of leukæmia. Dr. Edes, late of Harvard Medical School, was the first, in 1871, I think, to call attention to it. Peabody, of New York, has reported a case of six weeks' duration. Other references are given in Osler's article on Leukæmia in Pepper's system of medicine. The cause is not known.

Yours truly, X.

Philadelphia, Oct. 22, 1887.

Localized Sweating.

EDS. MED. AND SURG. REPORTER :

Sirs:—I noticed in the REPORTER, for Oct. 15, that Dr. Rice reports in the *British Med. Journal*, three cases of localized facial sweating, following a parotid abscess, and says it would be interesting to know of other cases. I know of a gentleman in our community, who had typhoid fever thirty-eight years ago, followed by an abscess of the left parotid, who has had localized facial sweating on that side ever since, especially while chewing on that side. He has also an epithelial tumor on the inside of the same cheek.

Yours truly, J. M. STANSILL, M.D.

Rockingham, N. C., Oct. 24, 1887.

Saccharin.

EDS. MED. AND SURG. REPORTER :

Sirs:—I have your note of the 24th of October, inquiring about saccharin, for the information of the readers of the REPORTER. In reply, I would say: Saccharin is worth about one cent a grain to-day, in prescription: by the ounce of course it is considerably less, say about \$2.00 to \$2.50. It is soluble in 500 parts of distilled water, at ordinary temperature, but very readily soluble in boiling water. It is very soluble in alcohol and ether, and forms soluble salts with the carbonates and hydrates of the alkaline metals. These salts are quite soluble in water.

Saccharin, when given internally or subcutaneously, is excreted completely by the kidneys in unaltered state. It is, therefore, not decomposed in the body; nor do the saliva or the fæces contain any traces of it, even after large doses. Unlike benzoic and salicylic acid, it is not converted into hippuric or salicyluric acid. It has scarcely any retarding effect on the digestion of either

proteids or hydro-carbons, and in fact is said to increase the diastasic action of malt. When given to man, in doses of from 15 to 75 grains, no injurious effect, or even disturbance of the appetite, is produced. The urine is not altered, either in specific gravity, quantity, or amount of urea and sulphuric acid; it, however, does not readily undergo fermentation. The amount of chlorides in the urine appear to be increased during the use of saccharin, while the phosphates remain normal. Animals on full diet, along with saccharin, increase in weight, and frogs may be kept alive indefinitely in neutralized watery solution of saccharin. Saccharin therefore is not possessed of any toxic or deleterious effects on the human organism. Its principal use in therapeutics is as a corrective for the taste of other substances, for employment in cases of diabetes mellitus, and in persons under treatment for the reduction of obesity. Dr. Dreschfeld has found that it relieved some of the troublesome symptoms of acid dyspepsia. One part of saccharin largely corrects the bitter taste of two parts of quinine, with which it unites chemically. It may be used for sweetening the food, or the coffee and tea of diabetic patients, either by the direct addition of a grain or two of saccharin, or it may be used in the form of a syrup made as follows:

Dissolve ten parts of saccharin and eleven parts of carbonate, or twelve parts of bicarbonate, of sodium in 1000 parts of distilled water, at a temperature of 40° (Centigrade), or 104° (Fahr.).

Yours truly, GEO. I. MCKELWAY.
Philadelphia, Oct. 25, 1887.

A Case of Dysentery.

EDS. MED. AND SURG. REPORTER:

Sirs:—I would like to get advice from some medical brother on the following case:

I have a case of dysentery in a woman about forty years old, which, since three months, has baffled another physician and myself. My patient is in pregnancy (four months), and decreases in strength every day. She passes from six to eight ounces of blood daily. Yours truly,

THEO. GRENIER, M.D.
Banks, W. Bay City, Mich., Oct. 20, 1887.

[Our correspondent probably has made a careful local examination of the anus and rectum to exclude the possibility of the bleeding being caused by hemorrhoids or any vascular morbid growth. If so, we would recommend him to try the effect of first, cool,

then cold water enemata, using first small and then gradually increasing quantities.—
EDS. REPORTER.]

Iodide of Bismuth for Chancre.

EDS. MED. AND SURG. REPORTER:

Sirs:—Since the introduction of iodoform, it has been used very extensively in surgery and surgical diseases. The great objection, of course, is its odor; and it is very difficult to effectually conceal it. Patients, as well as the physician, know the smell, and I have had persons object to its use in non specific diseases, saying that "persons who smell it on them will think they have some 'bad disease.'" In this country the Indians call for "chancre medicine" (iodoform) at the drug stores, and the increasing demand will no doubt force its regular issuance with the monthly rations.

I treat a great many cases of chancre and chancroid, and for a long time I have been using the sub-iodide of bismuth, and with very satisfactory result. It has no odor, and when used with the insufflator forms a thin bronze film over the sore, which is both protective and healing. The only objection to it is its intensely red color, which, if it is carelessly applied, may soil the linen.

So far as my experience goes, I have found it to possess all the virtues of iodoform without its disagreeable odor) both in venereal ulcers and in surgery.

Very respectfully,

W. N. SHERMAN, M.D.
Kingman, Arizona, Oct. 13, 1887.

Laparotomy too Late.

DR. C. W. DULLES, EDITOR OF MED. AND SURG. REPORTER:

Dear Sir:—During your recent illness you kindly sent me a patient upon whom you had been summoned to do an abdominal section. A brief outline of this case may be of interest to the readers of the REPORTER, and will warn practitioners against delay in similar cases. The history of the case pointed to a tumor of the uterus or ovary, with subsequent acute obstruction of the bowels. The local and general conditions were desperate. An examination showed marked symptoms of strangulation of the bowel and general peritonitis, due to an inflamed tumor, which was easily mapped out low down on the right side. The family was plainly told how few the chances for recovery would be, even with an operation for the removal of the tumor and the release of adhesions; but there was a chance and the family desired patient

to have the benefit of it. The patient and her family decided to have the operation performed. On opening the abdomen, I found a sloughing fibroid, or sarcoma, of the right ovary, about the size of a child's head. There were general adhesions and numerous strangulations by inflammatory bands. The small intestine was adherent to tumor from the sigmoid flexure to the cæcum. The large bowel about the ileo-cæcal valve was strangulated and gangrenous to the extent of some inches. Resection was out of the question. The strangulation had probably been of ten days' standing. The patient survived the operation only two hours.

This adds one more to the great number of delayed operations. The mortality in the removal of such tumors, if done early, or when the tumor is first discovered, would be about *nil*. Yours truly,

M. PRICE, M.D.

Philada., Oct. 10, 1887.

Correction.

EDS. MED. AND SURG. REPORTER :

Sirs :—In my article (REPORTER, Oct. 22, p. 558), I notice several errors which I would like to have corrected.

1st. Gen. *Opdyke* was the mayor, not Vandyke.

2d. The bandage was above the wound, the bite.

3d. Oil of tobacco, 20m to the oz., and not as stated.

4th. Maximum dose of strychnine was $\frac{1}{2}$ of a grain. I am sorry to trouble you.

Yours truly,

EDW. VANDERPOOL.

228 E. 68th St., N. Y., Oct. 24, 1887.

—Dr. J. Matthews Duncan says: It is an open question to what extent a great income truly elevates a professional man, to what extent a general high level of income elevates the profession—and one difficult of solution. It may be now passed over with the slinging of two stones from the brook. Who has done more to elevate the profession than John Hunter? And he died poor. Who have done more to degrade the profession than our unworthy rivals the quacks, whether within or without the regular ranks? They make large incomes, and not rarely leave great hoards of wealth behind them. It is not pelf on the one hand, nor is it philosophy on the other; it is science that has elevated our profession, maintains its high position, and by its growth will continue to aggrandize it.—*Brit. Med. Journal*.

NOTES AND COMMENTS.

Fracture of the Fifth Cervical Vertebra.

The *Lancet*, October 1, 1887, contains an account of a case under the care of Surgeon-Major Myers, in the Windsor Station Hospital, of unusually long survival after a crush of the body of the fifth cervical vertebra. The patient, a soldier, twenty-three years old, dived head foremost into water only two feet deep. He was taken out by his comrades and was found to be paralyzed in the legs, and devoid of sensation and motion in the lower part of the trunk and to about the lower angles of the scapulæ. There was some power of movement in both arms at the shoulder; respiration was entirely diaphragmatic; pulse slow and strong; the patient complained of no pain excepting at the back of the neck in the region of the fifth and sixth cervical vertebræ, and chiefly on the left side. He stated that while lying under water he knew he was quite paralyzed, but held his breath, hoping that assistance might be sent him.

Some days after admission the arms became motionless, excepting a slight power to raise the elbow from the side, and remained flexed. Sensation returned in the right arm, but it soon became apparent in the left arm as low as the elbow, and extending over the anterior surface of the radial half of the forearm, and at a later period in the tips of the thumb and first and second fingers. Over and above the shoulders there was marked hyperæsthesia. For many weeks bedsores were well kept in check, though continually threatening; but in course of time they formed in numerous places, especially along the under surface of the right leg, and even on the toes, where no pressure occurred. At a later stage the integument of the back became completely undermined and converted into a large sac, containing very offensive pus. This sac, by irrigation twice daily with disinfectants through the sacral bed sore, completely disappeared; and a short time prior to death the bedsores of the right leg had healed, and others over the scapulæ, elbows, and hips had nearly done so, and even the deep sacral bed sore had greatly contracted. Cystitis set in at an early stage, hastened probably by an acute attack of gonorrhœa, from which the patient was suffering on admission. This was completely arrested for a time by frequent irrigations with different disinfectants. Two months after admission the patient stated he could feel the flow of water from the irrigator into the bladder, and this regained

some power, the urine being occasionally expelled with force, though unconsciously to the man. After some months slight reflex action of the leg muscles could be obtained by the galvanic battery and by tickling the soles of the feet, and tended to increase to the last. Latterly, he began to raise both elbows to the level of his head, and flex the left arm sufficiently to enable him to touch his face with his fingers, but he could not bring the arms back to his side. Rotation of the head became quite free and painless, and considerable pressure could be borne over the seat of fracture without causing discomfort. The temperature rose irregularly till the evening of August 16th, when it reached 103.2° ; after that date it gradually became normal or subnormal, and, excepting occasional short and sudden rises, remained so until the last week. The action of the bowels from the first to the last remained involuntary. About the middle of April, 1887, his appetite, which had been surprisingly good, began to fail, the urine became fetid, vomiting set in, the bedsores began rapidly to reappear, and on April 28th urine ceased to enter the bladder. Vomiting then became incessant, and on May 2d the patient died.

At the post-mortem examination the cervical vertebræ were removed. The kidneys were completely disorganized. The right one being almost entirely converted into one fetid abscess. The ureters were much dilated and thickened, and deeply stained. The bladder was also much hypertrophied and stained, and contained only a little fetid pus. There was nothing special to remark about the thoracic organs. The brain was not examined. The body of the fifth cervical vertebra had been crushed and somewhat displaced backwards, giving rise to a projection in the spinal canal. Opposite this projection the spinal cord was almost completely disorganized, evidently by the pressure exercised upon it.

A Case of Cerebellar Tumor; Operation; Death from Shock.

Dr. C. W. Suckling, in the *Lancet*, October 1, 1887, gives an account of a girl twelve years old, with a neurotic family history, but free from phthisis or struma, who was admitted to the Queen's Hospital, Birmingham, on March 28, 1887. She had been in good health until two years ago, when she began to complain of headache and suffering from frequent morning vomiting. On her admission the symptoms were briefly as follows:

Headache, vomiting, double optic neuritis, nystagmus, facial paralysis on the left side, slight hemiplegia on the right side, diplopia, vertigo, staggering to the left, and inability to rotate the eyeballs outwards. The diagnosis of brain tumor was rendered certain by the symptoms just mentioned, and the staggering gait pointed to the cerebellum as the seat of the growth. The diagnosis was glioma of the left lobe of the cerebellum. As the mother desired the child to have the benefit of an operation, Dr. Suckling transferred the patient for this purpose to Mr. Jordan Lloyd, who performed the operation according to the method advocated by Mr. Horsley. A soft, very vascular tumor was found occupying the left lobe of the cerebellum, part of which was removed, with considerable hemorrhage. The patient soon sank into a collapsed condition, from which she rallied somewhat in twelve hours, and was able to speak rationally. She died, however, in collapse, forty-eight hours after the operation.

At the autopsy a large tumor, proved by microscopic examination to be gliomatous, was found to occupy nearly the whole of the left lobe of the cerebellum, and to have invaded the middle lobe also.

This makes the third operation for removal of a tumor of the cerebellum, and all three patients have died from shock. Dr. Suckling thinks that operation is justifiable, considering the otherwise hopeless nature of the disease, but that the only hope for success lies in early performance of it.

Impure Drugs in New Jersey.

Under the provisions of the "Food and Drug Act," passed by the last Legislature, the Dairy Commissioner of New Jersey is empowered to examine foods and medical products offered for sale in this State, for the purpose of testing their purity. Assistant Dairy Commissioner McGuire has been visiting drug stores in the different parts of the State, and has found that many pharmacists have adulterated the drugs and chemicals sold by them. Mr. McGuire discovered that with drugs such as laudanum, spirits of nitre and purgatives in common use the adulterations had made them below the United States pharmacopœia standard. At one place, Mr. McGuire collected twelve samples of different drugs from the drug stores and found one-half far below the standard. In another, he was surprised to find that nearly all of the seidlitz powders exposed for sale were only about half weight.

Homœopaths' Opinion of Homœopaths.

At the opening ceremonies of what is to be known as the "Hering Building" of a Hospital established by the "Women's Homœopathic Association of Philadelphia," one of the speakers thus referred to the large number of so-called homœopaths who look one way and now another: "This occasion gives us joy because it occurs in the interests of truth and uprightness—truth as opposed to ignorance and falsehood; uprightness as set against cowardice and dishonesty. Long enough has the spurious been passing for the genuine. For long has public confidence been misled and the community deceived; and now, through the stand which the management of this hospital has taken, and which this event celebrates, you cause us to hope that the cloud is to be lifted from the hearts of those who have long deplored a state of things they were powerless to change. Hahnemannian homœopathy is to be the rule of practice in this institution. The unmixed and pure law is to have full sway. The weights of stupidity and duplicity that have so often and so long hindered the soaring aloft of this wonderful truth have been cast away."

That is plain enough; and we wish its significance could be grasped by the community so that those who call themselves homœopaths, but are not such, could be separated from those who are homœopaths sincerely and consistently. Then we should see what the latter could do without getting surreptitiously help from the practices of the regular practice.

Treatment of Neuralgia by Intense Cold.

Dr. George W. Jacoby, in a paper read before the American Neurological Association on this subject, says:

The subject of this paper is not by any means new, but since 1884 our methods of applying cold therapeutically have been, so to say, revolutionized, and this has been accomplished by the introduction of chloride of methyl into our therapeutic armamentarium. Since Debove recommended this agent for the treatment of sciaticas, reports of so many successes with its use have been received from other quarters that we simply cannot avoid paying some attention to the matter. Since Debove's first publication I have, at different times, given considerable attention to the therapeutic action of the various refrigerants, and have finally come to the conclusion that we possess only two which can be easily and practically utilized.

These are the chloride of methyl and the fluid carbonic acid.

The method of application is as follows: The screw at the top of the copper cylinder containing the chloride of methyl is opened, and the opening of the atomizer is then directed obliquely against the part to be treated. The jet is then moved over the entire course of the nerve, also being applied to the surrounding parts. During the entire application the cylinder must be held in the left hand, and the right one must not be removed from the regulating apparatus.

The length of time during which it is admissible to act upon one spot cannot be estimated in seconds, but will depend upon the coloration which the skin assumes. As soon as it grows very pale the jet must be displaced. This occurs in a few seconds, but will vary in different places, according to the thickness or thinness of the skin. The skin must be continually under observation, and the apparatus displaced at the proper time. As the skin becomes pale it also becomes hard, and the patient complains of a burning feeling. As soon as the entire nerve has been acted upon in this manner, the patient is generally free from pain. In the majority of cases the pain returns again, after a few minutes, at certain points. These must be at once treated again, and thereupon the pain will be entirely gone.

Relief after the first application is the rule, but sometimes a second one is necessary. As stated, the spray must be directed obliquely against the skin, and not vertically, for in the latter case the great pressure produces a depression of the tissues, and this depression is the frequent seat of a blister or an eschar. A large surface must also be acted upon, as the success is to a great extent dependent upon this. Sluggishness of circulation, with reduced vitality of the skin, would contraindicate its use. There are certain objections to its use, which, however, are only of relative importance.

The pain produced by the applications is rather severe, but it is never as great as that produced by the actual cautery or the galvanic brush. Hyperæsthesia and redness of the skin remain in some cases for hours, and even for days. Vesications and eschars may be produced if sufficient care is not taken in the application; but Debove, in 1885, said that he had then used it over a hundred times without producing an eschar.

My general impression, from this brief experience, is that we have in the chloride of methyl a reliable analgesic, which does not affect the general condition of the patient,

and that it is invaluable in the treatment of neuralgias for the immediate relief of severe pain. On account of the difficulty of obtaining the chloride of methyl, I made use of the condensed carbonic acid for the treatment of the cases of sciatica which came under my observation.

In short, my conclusions are that the carbonic acid, used as above stated, is, in the absence of the chloride of methyl, able to take its place in the treatment of sciatica. That the pain is relieved very promptly by its use, but that its curative effect is not as great as that attributed to the chloride of methyl by other observers. If future observations show that in intense cold we possess a remedy which is capable only of relieving pain, we still will have very valuable remedies in the chloride of methyl and carbonic acid, remedies which all of us, who have at times found it almost impossible to relieve the intense sufferings of some of our patients, will know how to appreciate.

Ever since reading the "Bradshaw Lecture" for 1883, by John Marshall, I have come to agree with this author that in very many cases the neuralgic pain is situated in the nervi nervorum. At that time the existence of these nerves was only surmised by Marshall, but since then Mr. Victor Horsley has satisfactorily proven their existence. Now admitting, as we must, the existence of these nerves, we can easily understand that they must be acted upon much more intensely by the severe cold than the underlying nerve-fibre itself, and that in many instances they are entirely destroyed, or, at any rate, completely paralyzed.

Thus I account for the cases of permanent cure, which of necessity must also be a rapid one. Certainly, I am far from believing that the pain in all cases of neuralgia is in the nervi nervorum, and consequently in those cases in which the seat of pain is in the nerve-fibre itself, this seat not being so accessible to the freezing process, the pain will necessarily return after a longer or shorter interval.—*Med. Record*, October 8, 1887.

Rhus Aromaticus for Enuresis.

Dr. May, of Brussels, has had very good results in the treatment of children suffering from nocturnal incontinence of urine with from 20 to 50 drops daily, in three doses, of a tincture of *rhus aromaticus*, prepared by macerating 200 parts of the bark in 1000 parts of alcohol, at a temperature of 64° (Fahr.).

NEWS AND MISCELLANY.

Fraudulent Life Insurance.

Some time since, one Von Scheurer, a Bavarian by birth, a naturalized American, had his life insured for 300,000*fr.* in three British companies—the amount to be paid to Von Bakfalua, his mistress. Finding the premiums heavy, he thought the insurance money would be preferable, and devised an ingenious plan to secure it without the silly formality of dying. To this end he procured the assistance of "Dr." Castelnau, under promise of a share in the plunder. The "Doctor" is a character. Although not a graduate of the Faculty, but only at one time an *interne* at the St. Lazare Hospital, he was some thirty-five years ago the editor of a medical paper notorious for its virulence. He was also known as a model socialist and popular agitator. Of late years he was a contributor, under the name of Dr. Lux, to Rochefort's paper, the *Intransigeant*, always bitterly attacking Pasteur. At Mme. Huot's anti vivisectionist lecture, he sat next to her on the platform, and was conspicuous because he has no nose to speak of, and persisted in addressing the audience as "citoyens et citoyennes" in a snuffling voice. He had not been prosperous—he is now seventy-two—and it is said the hope of getting money enough to buy a pharmacy for his son led him to join Von Scheurer in the conspiracy. First they approached one L., a consumptive, who expecting to die, consented to personate the Bavarian for the sake of ease and comfort during his last days. So he was placed under the name of Von Scheurer, in a "Maison de Santé" at Bellevue. But there he was so well cared for that he recovered. The conspirators then looked for a better subject. One was supplied by a pharmacist of the Rue Geoffroy-St. Hilaire, named Martinet, also a shining light of the Socialist party, but who is thought to have acted innocently, under the belief that some new cure for consumption was under trial. The second patient, a Swiss called Glockner, in the last stages of phthisis, was then, under the name of Von Scheurer, installed in Dr. Castelnau's house at Meudon, where he soon died, and was buried in November, 1883. The legal mortuary papers having been duly obtained, the British companies paid the insurance money to Mlle. Von Bakfalua, and the German-American, after giving the Doctor, 25,000*fr.*, it is said, decamped with her to New York, where they now may possibly be riding in

Fifth Avenue or the Riverside Park. But it is different with Dr. Castelnau. On some information he was arrested a few days ago, and is now in jail at Versailles, under the charge of conspiracy and murder. The body of Glockner is to be exhumed for judicial investigation. M. Martinet has also been taken to Versailles jail, and so have Dr. Castelnau's son, son-in-law, and a servant girl. Many wild stories are circulating, hatched by inventive Parisian reporters, but the foregoing details are in the main supported by reliable evidence.—*Chemist and Druggist*, October 1, 1887.

Bay Rum Trade-Mark Case in Germany.

A lawsuit has just been brought against the Hamburg perfumery firm of C. Riese, for having fraudulently used the registered trade-mark of Mr. H. Michelsen, of St. Thomas, West Indies, on bay rum sold by the defendant. It appeared that Mr. Riese had been for many years in business relations with Mr. Michelsen, from whom he bought bay rum in casks, afterwards bottling it in Hamburg, and providing it with labels similar to those used by Mr. Michelsen himself, and apparently with the latter's knowledge. In 1884 Mr. Michelsen instructed his Hamburg agent, a Mr. J. D. Saune, to enter his trade-mark in the German register, a proceeding of which the firm of Riese was informed in 1885. As soon as the defending firm heard that Mr. Michelsen's trade-mark had been registered in Germany they wrote to the St. Thomas House, requesting permission to continue the use of the trade-mark on the bottle-labels, and while awaiting an answer to this request they continued to affix the label to the bottled bay rum which they sold. Mr. Michelsen wrote declining to allow the continued use of his trade-mark, whereupon Mr. Riese substituted another label, which was now complained of being a colorable imitation of the St. Thomas trade-mark. The genuine labels consisted of a representation of a bay rum leaf on a white background, with the words "Bay Rum. H. Michelsen in St. Thomas," whereas those used by Mr. Riese contained the same leaf on a golden background and bore the legend "Bay Rum of H. Michelsen in St. Thomas." On behalf of Mr. Riese it was shown that the latter did buy all the bay rum bottled by him in bulk from Mr. Michelsen's firm only, and that Mr. Michelsen had omitted to have his trade mark entered at Leipzig, where a register of foreign trade-marks protected in Germany is kept as well as at Hamburg. In

the result the Court decided against the St. Thomas manufacturer.—*Chem. and Druggist*, July 30, 1887.

Cholera at New York.

The committee appointed by the College of Physicians of Philadelphia to investigate the efficiency of quarantine arrangements for the exclusion of cholera at New York, which was composed of Doctors J. C. Wilson, E. O. Shakespeare and R. A. Cleeman, made its report to the college on October 28. From this report it seems that the committee finds it necessary to condemn the carelessness in respect to cleanliness among the passengers; the fact that cisterns are in the ground and accessible to the immigrants; that windows are in the disinfecting chambers; that there is a temporary hospital room opposite a lavatory; while there is no resident physician to alternate on duty. They further object to lack of official supervision of the personal hygiene of the immigrants; promiscuous heaping of blankets and bedding when the disinfectant floor washing was done, the occupation of beds by more than one sleeper, the successive use of bedding by different people, the absence of a resident physician even at the hospital, and the presence of male nurses in charge of female patients; the return of convalescents to Hoffman Island from the hospital without the disinfecting bath, and the lack of precautions against the presence of small boats which may communicate with the surrounding country. The report also suggests the prohibition of vessels from the infected Italian ports.

At the conclusion of the reading of the report the following resolution was unanimously adopted:

Resolved, That in order to secure concerted action among the medical societies of the United States looking to the early adoption of a uniform and efficient quarantine of all exposed ports, the committee be continued and be authorized to issue an address to medical societies of the country, and seek their co-operation.

Another Abortionist Brought to Grief.

Thomas B. Miller, who claims to be a Methodist clergyman as well as a physician, and who was "Dean" of the so-called Philadelphia University, conducted by Dr. Buchanan, some time since sent to prison for his offences, was on October 21st convicted of criminal malpractice and sentenced to an imprisonment of seven years in the Eastern Penitentiary of Pennsylvania.

—The American Association for the cure of Inebriety will begin its semi-annual meeting at the Turkish Bath Hotel, Brooklyn, on November 9th. The following is a list of the papers and addresses to be read: *The President's Address*, "On the Responsibility of Inebriety," will be delivered by Joseph Parrish, M. D., Burlington, N. J.; "*Report of the Colonial Congress on Inebriety*," London, by T. D. Crothers, M. D., Hartford, Conn.; "*The Pathology of Inebriety*," by Dr. Norman Kerr, London, England; "*The Physiology of the Drink Impulse*," by Dr. J. T. Searcy, of Tuscaloosa, Ala.; "*Cocaine Toxæmia*," by Dr. J. B. Mattison, of Brooklyn, N. Y.; "*The Power of Alcoholic Influence*," by Dr. T. L. Wright, Bellefontaine, Ohio; "*Turkish Baths in Inebriety*," by Dr. C. H. Shepard, Brooklyn; "*Hygiene in the Treatment of Inebriety*," by Dr. Albert Day, Boston; "*Report on Asylums for Inebriety in New Zealand and Australia*," by Dr. D. McGregor, Government Inspector, New Zealand; "*Sexual Insanity in Inebriety*," by Dr. T. D. Crothers, Hartford, Conn.

News Items.

—"Gentlemen," said a German professor, "I begin to-day my lectures on the practice of medicine. When a man is sick, nature and the disease are in conflict. The physician comes in and strikes at the disease. If he hits it, the man gets well; but—if he hits the man, it is all up with him."—*Zur Gene-sung*.

OBITUARY.

DR. S. B. KIEFFER.

Dr. S. B. Kieffer, a leading practitioner in Cumberland county, Pa., died October 28, 1887, aged 64 years. He was born in Franklin county, Pa., in 1823, and was graduated from Franklin and Marshall College in 1848. He was President of the Pennsylvania Medical Society, and was a member of the American Medical Association.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Oct. 23, 1887, to Oct. 29, 1887:

Major Chas. R. Greenleaf, Surgeon, will proceed from this city to the place hereinafter named, in the order in which they are named, for the purpose of investigating the methods of examining recruits at the depots and rendezvous located thereat, and of instructing recruiting officers in matters pertaining to such examinations: Baltimore, Md.; Philadelphia, Pa.;

Camden, N. J.; New York City and David's Island, N. Y.; Boston, Mass.; Portland, Me.; Albany and Buffalo, N. Y.; Cleveland, Ohio; Detroit, Mich.; Chicago, Ill.; Milwaukee, Wis.; St. Paul, Minn.; Jefferson Barracks and St. Louis, Mo.; Cincinnati and Columbus, Ohio, and Pittsburg, Pa. S. O. 240, A. G. O., Oct. 25, 1887.

Major P. J. A. Cleary, Surgeon, ordered to proceed from Ft. Huachuca to Ft. McDonald and report to the commanding officer for duty as Post Surgeon. S. O. 111, Dept. Ariz., Oct. 10, 1887.

Capt. Paul R. Brown, Assistant Surgeon, leave of absence extended one month. S. O. 250, A. G. O., Oct. 27, 1887.

Capt. H. G. Burton, Assistant Surgeon, ordered from Plattsburg Barracks, N. Y., to Watervliet Arsenal, N. Y.

Capt. J. C. Merrill, Assistant Surgeon, ordered from Watervliet Arsenal to Frankford Arsenal, Pa. S. O. 249, A. G. O., Oct. 26, 1887.

Capt. Chas. Richard, Assistant Surgeon, granted leave of absence for one month, to take effect when his services can be spared by his post commander. S. O. 247, A. G. O., Oct. 22, 1887.

First Lieutenant Nathan S. Jarvis, Assistant Surgeon, ordered for field duty in Dept. of the Platte. S. O. 246, A. G. O., Oct. 21, 1887.

First Lieutenant Nathan S. Jarvis, Assistant Surgeon, ordered from Dept. Platte to Dept. Missouri, for duty in the field. S. O. 249, A. G. O., Oct. 26, 1887.

List of Changes in the Medical Corps of the U. S. Navy, during the week ending Oct. 29, 1887:

Medical Inspector N. L. Bates, ordered to hold himself in readiness for orders to the "Trenton."

Assistant Surgeon F. A. Hesler, ordered to examination for promotion.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the three weeks ended Oct. 29, 1887:

P. H. Bailhache, Surgeon, to proceed to Buffalo, N. Y., Erie, Pa., Ashtabula, Cleveland, Sandusky, and Toledo, Ohio, as Inspector, Oct. 14, 1887.

C. S. D. Fessenden, Surgeon, detailed as Chairman of Board for the physical examination of cadets, Revenue Marine Service, Oct. 15, 1887. To proceed to Cape Charles Quarantine Station as inspector, Oct. 26, 1887.

H. W. Satelle, Surgeon, detailed Chairman of Board for the physical examination of officers, Revenue Marine Service, Oct. 27, 1887.

Fairfax Irwin, Passed Assistant Surgeon, to inspect unserviceable property at Boston, Mass., and Portland, Maine, to proceed to Vineyard Haven, and New Bedford, Mass., as Inspector, Oct. 8, 1887.

F. W. Mead, Passed Assistant Surgeon, detailed Recorder of Board for the physical examination of cadets, Revenue Marine Service, Oct. 15, 1887.

J. H. White, Passed Assistant Surgeon, leave of absence extended four days. Oct. 21, 1887.

P. M. Carrington, Assistant Surgeon, detailed as Recorder of Board for the physical examination of officers, Revenue Marine Service, Oct. 27, 1887.

J. B. Fattie, Assistant Surgeon, granted leave of absence for seven days. Oct. 28, 1887.

—J. Pettus, Assistant Surgeon, when relieved at Savannah, Ga., to proceed to Galveston, Texas, and assume charge of the Service, Oct. 17, 1887. Granted leave of absence for thirty days, Oct. 21, 1887.

J. J. Kinyoun, Assistant Surgeon, granted leave of absence for fifteen days, Oct. 19, 1887.

CLINICAL LECTURE.

COMPRESSION OF ONE HALF OF THE SPINAL CORD: BROWN-SE- QUARD'S PARALYSIS; LO- COMOTOR ATAXIA.

BY M. ALLEN STARR, M.D.,

Professor of Diseases of the Nervous System in the
New York Polyclinic.

Gentlemen:—The patient whom I show you first to-day is suffering from a disease which is very rare.

The patient is a girl fifteen years of age. She says she was perfectly well until three months ago. The only instance of traumatism was a fall from a window eleven years ago, from which no serious symptoms resulted.

Three months ago, she began to suffer from pain and stiffness in the neck. She then began to hold the head in the position in which you now see it, turned somewhat to the right, the chin slightly elevated and pointing toward the right shoulder. When I attempt to move her head with my hands, she resists very perceptibly. I am able to move it only very slightly, while the patient cannot move it except by turning the body. This stiffness of the neck is accompanied by pain running up over the back of the head. The pain is made worse by movement.

After this condition had continued about one month, she began to grow weak in the legs and arms. This weakness has continued up to the present time, and has grown somewhat worse.

Lately, she has noticed that the power of the left arm is less than that of the right, while the sensation in the right arm is less than that in the left. So much for her history as she has related it.

We will now make a careful examination of her present condition. You see at once that she is unable to turn her head to the left side; she is unable to innervate the right sterno-cleido-mastoid muscle which turns the head to the left, and the muscles of the neck are quite rigid, their contraction being independent of the will.

The neck is peculiarly prominent. It looks almost as if she had a goitre. The back of the neck is not only flat, but it curves forward in a manner so that I can place my finger in the depression; there is not that prominence of the vertebræ usually seen, especially of the fifth cervical. In your own necks there is a prominence at this point, while in hers there is a depression. When I put my finger into her mouth and feel the vertebræ at the back of the pharynx, there is a decided projection of the bodies.

She says she is weak in both legs; that she is unsteady on them; but there is no apparent ataxia. There is marked weakness in ordinary walking. I find marked flexor weakness in the left leg. I can bend the knee easily, although she opposes me. The right knee I am unable to bend; the flexor weakness on this side is very slight. There is hardly any difference between the two legs with regard to extension.

There is more sluggishness in flexion of the left foot than in flexion of the right foot.

The grip of the left hand is much weaker than that of the right.

The motions of the left forearm and arm are very limited, and although both arms are weak, the left is far worse than the right. There is in the left arm great exaggeration of the triceps tendon reflex, causing a trembling, wavy motion of the forearm on a single percussion at the elbow which I have never before seen. The motion resembles that of the foot in ankle clonus. The tendon reflex is also present at the wrist in the left hand. The patellar tendon reflex is very much exaggerated on the left side, and ankle clonus is also readily elicited; it is absent on the right side. The tendon reflex is much less marked in the right than in the left knee. There is slight tendon reflex at the right wrist.

She says that during the past two weeks she has had some difficulty in the control of her bladder. She has to evacuate the viscus very soon after the need arises. She has not yet had any dribbling of urine. But she is aware of the fact that her control over the bladder is not what it ought to be. That is another important symptom. The same is true of the rectum.

Now we come to sensation. She says her limbs are not steady. Steadiness of motion depends largely upon the muscular sense. There are two cases of locomotor ataxia present, which illustrate this fact, the men being strong in the legs, but unsteady. When this girl attempts to stand with the feet close together, she is unsteady. Her hands do not move with precision. This is not due alone to weakness of the arms, but in a degree to loss of muscular sense. Romberg's symptom, inability to stand steadily with the eyes closed, is manifest to some extent. It is called Romberg's symptom because Romberg, of Berlin, was first to elicit it. It is a very common symptom in locomotor ataxia, and indicates lack of perception of muscular impressions from the legs.

Precision of movement in walking is impossible with this patient. You see how she staggers, especially when she attempts to walk backward with the eyes closed. She seems to stagger more to the right side than to the other side. We see, then, a certain amount of ataxia in this patient's legs as well as loss of power.

When she tries to bring the index finger of her right hand to mine, or to her nose, when her eyes are closed, it tends to shake, showing some loss of muscular sense. Her left hand is too weak for this test, as she cannot lift the hand at all. I have placed her left hand in a particular position, and asked her, with her eyes closed, to place the right hand

in a similar position, which she has done. The same test for the other hand is less quickly responded to, showing impairment of the muscular sense of the left side.

We will now test the sense of touch. The most delicate test is by means of a piece of cotton-wool. We find slight anæsthesia to a touch on the right side. You will remember that the paralysis is most marked on the left side. The anæsthesia is less marked in the left than in the right leg, and less marked in the right leg than in the right hand.

She perceives sensations of cold very much better on the left side than on the right. She perceives sensations of heat on both sides, but more acutely on the left side.

The line of anæsthesia to touch extends up on the right side to the shoulder; it is not marked on her neck, and there is no anæsthesia on the left side at the shoulder; rather a peculiar fact.

Sensation on the face is normal, and she notices no difference between sensations on the face and on the left limbs, which indicates that there is no hyperæsthesia in them.

What, then, have we in this case? We have partial paresis with increased tendon reflexes on the left side of the body, and partial anæsthesia on the right side. Now, that is characteristic of only one form of spinal disease, called Brown-Séquard's paralysis, after Brown-Séquard, who was first to describe it. It is produced by a unilateral lesion of the cord. I have here a diagram showing two segments of the spinal cord, with the tracts passing through them,—from this you will see that the motor nerve fibres coming from the brain cross over and descend at the medulla, in the lateral pyramidal tract of the cord, to supply the muscles of the opposite side of the body. It can also be seen that the posterior nerve roots, on entering the cord, cross over at once to the opposite side, and there ascend in the posterior column to the medulla and brain. It is evident, from this arrangement of the motor and sensory nerve fibres in the cord, that a lesion limited to the left side of the cord will interfere with the motor nerve tract governing the left limbs, and with the sensory tract coming from the right limbs. In other words, a unilateral lesion in the left half of the spinal cord in the cervical region will produce paralysis of the left limbs with regard to motion, and anæsthesia of the right limbs with regard to sensation. No other lesion in the cord will produce such a trouble. It is evident, therefore, that this girl has some trouble in the left half of her

cord. To what can that trouble be due? We have a peculiar forward projection of one of the cervical vertebræ; we have a marked stiffness of one side of the neck, and a depression posteriorly where there is projection anteriorly of the fifth cervical vertebra. Therefore, I think we may say this patient is suffering from compression of the spinal cord due to displacement of one of the vertebræ following disease. The pathological condition is undoubtedly one of caries of the body of the fourth or fifth cervical vertebræ, possibly of both, and the symptoms are all due, primarily, to disease of the vertebræ, but secondarily to disease of the nerves and cord, set up by the trouble in the vertebræ. One of the first symptoms produced by caries of the vertebræ is interference with the conduction of impulses through the nerves which pass out between the vertebræ. That is true in this case, as it is the cervical nerves which go up to supply the back of the head and innervate the deep muscles of the neck. It has only been by watching this case for sometime that we have been able to draw a picture of the disease perfectly characteristic of a spinal lesion.

Under these circumstances the prognosis is rather unfavorable. The danger is that this carious process will go on; that there will be a greater amount of pressure on the cord. The fact that she already has weakness in both legs, and some weakness in the right arm as well as in the left, shows that the pressure upon the cord is now considerable, interfering with conduction not alone on one side, but upon both. In other words, interfering somewhat with conduction in the right half of the cord, but to a greater extent with conduction in the left half. So that already, at the end of three months, she has come into a condition which is pretty serious. And further, the pressure is exerted very near to the level of the cord from which the phrenic nerves arise, hence she is in some danger of death by their paralysis.

What can we do for her? The first thing, of course, will be to treat the cause of the trouble. You can not treat the paralysis or the anæsthesia in a case of this kind. You have first to remove the pressure from the spinal cord. That will have to be done by very careful adjustment of apparatus which will separate the vertebræ slightly from one another. That will take off the pressure consequent upon assuming the upright position. You will remember that she said she was more comfortable lying in bed than sitting or standing. Therefore, rest in bed and proper apparatus will prove of great value in

a case of this kind. I shall send her to Dr. Gibney, who is in charge of the orthopædic department, who can, I doubt not, construct such an apparatus as will support the head, and take off the pressure which is being made upon the cord and diseased vertebræ. If the condition has not gone on too far it may be that the pressure on the cord can be removed. It is amazing to what an extent the spinal cord will recover its functions after pressure upon it has been removed. We often see in caries of the dorsal region complete paralysis of the legs, which has existed for some time, disappear after removal of pressure upon the cord by suitably applied apparatus. It may be some time before the paralysis disappears. In one case which I recall it required three years, but at the end of that time it had disappeared entirely. If the compression has gone to the extent of producing disintegration of the elements of the cord and a transverse myelitis, of course the prognosis is worse. But, even in a case of transverse myelitis, if it has not gone on to absolute disintegration, breaking the continuity of the tracts in the cord, there may be a considerable degree of recovery. The treatment must be carefully carried out, largely by apparatus.

I will next show you two cases of locomotor ataxia.

The outline of this man's history is, that about eight years ago he began to have disturbance of vision, which has progressively increased until for two years past he has been unable to read. The trouble with the eyes was the first symptom in this case. That is an important fact, because many patients consult the physician with regard to trouble with the eyesight, and it does not occur to them to test the tendon reflex at the knee. This should be done in every case of failing eyesight. This man first consulted Dr. R. H. Derby for his eyesight. Dr. Derby examined the discs, and found a very advanced degree of atrophy of the optic nerves, which is a symptom of locomotor ataxia. He made the diagnosis, and very kindly sent the patient to me. I found in addition to the trouble in the eye a marked degree of ataxia. But this has come on only during the last two years; consequently the eye trouble preceded the ataxia six years.

I have no doubt that at the time this man's eyes began to trouble him he had lost the tendon reflex at the knee. I can strike the tendon below the knee as hard as possible, and get absolutely no response. Loss of tendon reflex at the knee, combined with

eye symptoms, should always awaken your suspicions of locomotor ataxia. If you will watch such a case long enough you will generally find the patient complaining of lightning pains and symptoms of ataxia.

The sequence of symptoms in this case has been, first, eye trouble; second, slight pains; third, ataxia; fourth, slight loss of control over the bladder, and, lastly, tingling in the fingers.

Our second patient's symptoms date back about eight years. He has been near-sighted all his life, he says, but no changes in the eyes have taken place since the development of symptoms of locomotor ataxia; there are no changes in the optic nerve. In this respect the case is quite in contrast with the other. He has shown weakness in the limbs, staggering gait, slight shooting pains, which have never been severe. Both of these cases are interesting, from the almost complete absence of lightning pains, which are present in most cases of locomotor ataxia. The books tell us that the first symptom of this disease is lightning pain, but our experience tells us that there are quite a number of tabetic patients who do not have lightning pains to any great extent. Here are two men who have passed the stage for the pains, and entered the stage of ataxia, and neither has suffered to any great extent from lightning pains. This symptom, however, is present in the majority of cases, and it is that which often leads to locomotor ataxia being mistaken for rheumatism.

This second patient complains of feeling more tired in the morning than on going to bed. Often this feeling of fatigue is one of the first symptoms of locomotor ataxia. This man has complained of it throughout.

There has been some sluggishness in setting up the mechanical action of micturition.

Both of these men have marked absence of tendon reflex; it is entirely absent in this patient. You see when he walks marked ataxia; it is much more noticeable when he walks backward; the foot swings irregularly to a certain extent; when he closes his eyes the ataxia becomes worse; with the eyes shut and the feet placed close to each other, Romberg's symptom at once develops. There is, therefore, no doubt of the diagnosis in this case.

Allow me to call your attention to the existence of what is known as the Argyll Robertson pupil. In both cases when I expose the eyes suddenly to the light there is absolutely no contraction of the pupils; but they do contract in accommodation. In both

cases the right pupil is constantly larger than the left. This irregularity in the size of the pupils is accounted for in one case by the existence of old adhesive iritis in the right or larger pupil. Both of these men have had syphilis. There is a controversy at present as to whether locomotor ataxia is always due to syphilis. Some say ninety per cent. of the cases are due to this disease, while others claim that not more than fifty per cent. of the cases can be attributed to syphilis. It so happens that in these two cases there is a history of syphilis, yet antisyphilitic treatment has had no effect. That I think you will find is very frequently true. It is only in a small proportion of cases of locomotor ataxia that antisyphilitic treatment has any effect, and in these cases the disease comes on within three years after the initial lesion, and is very rapid in its progress. These two patients are both in the second or ataxic stage of the disease. Now, what is the pathological change present? Neither patient has had much trouble with tactile sense, pain sense, or temperature sense. Both of them have had a great deal of trouble with the muscular sense.

The lesion in this disease is that illustrated in this diagram. It consists of sclerosis of the posterior columns of the spinal cord, primarily of the columns of Burdack, or what is known as the posterior root zone. It is known as the posterior root zone because here enter some of the fibres of the posterior nerve roots. Now, sclerosis beginning just at this point will interfere with the conduction of impulses coming in through the sensory nerves to the gray matter of the cord. It not only interferes with the entrance of sensory impulses, but it also interferes with the nutrition of these posterior nerve fibres, for the posterior nerve roots are nourished by the spinal ganglion outside the cord. If the nerve is cut off from the ganglion at any point, it degenerates from that point upward. We know that the posterior nerve roots enter the cord at the root zone, and some of them at least turn up to go to the brain. These lower roots, made up of fibres coming from the legs and trunk, pass up through the column of Goll; the fibres from the arm go up through inner part of the column of Burdack. In the posterior root zone enter the fibres which convey sensations of pain, and of the muscular sense and some of the fibres which convey touch and temperature. The fibres which pass directly into the posterior horn by its apex, the fibres related to the sensation of touch, escape to some extent, consequently the sensations of

touch are less impaired than those of temperature, pain and muscular sense.

What is the explanation of the lightning pains? The sclerosis in this area of the column of Burdack produces pressure upon the nerves there entering the cord. Some of these fibres convey the sensation of pain. If they are excited either by the prick of a pin at the periphery or in any part of their course, the same sensation will be elicited, a sensation of pain. You know perfectly well that whether the ulnar nerve be irritated by pricking the little finger or by compressing it at the elbow, the sensation will be felt in either case at the little finger. And if the ulnar nerve roots be compressed just as they enter the cord the sensation will be felt at the same place, namely, at the little finger. Both of these patients have felt pains in the little fingers and in the legs, but the trouble lay not in the fingers or legs, but in the cord, as just explained.

How can we explain the existence of the Argyll Robertson pupil, as it is called? Why it should occur in cases of spinal disease, especially in locomotor ataxia, we cannot say; but as a matter of fact, the symptom is due to an interruption in the reflex arc. The spinal reflexes are also interrupted. We know that sensations coming in at the posterior part of the cord and passing forward to the anterior horn to give rise to knee jerk, are interrupted in their course in locomotor ataxia. This interruption takes place at the point of sclerosis in the posterior root zone. In a similar manner (by interruption of the reflex arc), do we explain the Argyll Robertson pupil.

This diagram represents the optic nerve with its fibres passing to the corpora quadrigemina. From the anterior surface of the crus cerebri, beneath the corpora quadrigemina, is seen emerging the third nerve, which regulates the contraction of the pupil. The impulse comes from the retina, passes into the corpora quadrigemina, and passes from them downward to the nucleus of the third nerve. Now, it is at a point between the corpora quadrigemina and the third nerve nucleus that the interruption takes place, which interferes with contraction of the pupil to light. In the second patient there is no affection of sight except myopia from early youth; therefore we know that his Argyll Robertson pupil is not due to any trouble in the optic nerve. In the first patient there is gray atrophy of the optic nerve, but that might have come on long after the Argyll Robertson pupil. If this affection of the pupil is not due to disease

of the optic nerve, may it not be due to a lesion of the third nerve? It cannot in these cases, for neither of them has paralysis of the third nerve. If they had, there would be external strabismus, dilatation of the pupil, and ptosis.

If then the Argyll Robertson pupil is not due to disturbance in either the optic nerve, or the third or oculo-motor nerve, it must be due to a disturbance either in the nuclei of these two nerves or in the tract which joins the nuclei. That the trouble is not in the nuclei themselves is evident from the fact that there is absence of blindness in one case and of strabismus in both. Why the lesion should lie in the tract connecting the nuclei of the optic and of the oculo-motor nerves in locomotor ataxia, we do not know. The hour is too late to allow any further discussion of these cases.

A word with regard to treatment. Both patients are receiving Fowler's Solution, in from four to six drop doses, three times a day. That is the treatment which all my patients with locomotor ataxia receive at present. It is a treatment for which we can give no other reason than an empirical one. We simply know that it has had a favorable effect in a large number of cases. Gowers, I believe, was the first to treat cases in this manner. Since the publication of his article I have put all my patients with locomotor ataxia upon arsenic. A number have improved in many respects. A cure, after a sclerotic process has occurred in the cord, is, I believe, impossible. I have never seen the slightest evidence of improvement from the use of galvanism to the spine in these cases. I often use it, for some authorities claim that it is of benefit, and I am willing to give my patients the benefit of the doubt.

—A meeting of ex-resident physicians of the Philadelphia Hospital, Blockley, was held on October 25, at the College of Physicians, for the purpose of forming a permanent organization. Among those present were Professors Gross, Wood and Harrison Allen, Drs. De Forrest Willard and James B. Walker. On motion of Dr. Wood, a committee of six was appointed to arrange for a permanent organization. It was decided to hold the annual banquet sometime during the winter months, the date to be left to the discretion of the committee. Dr. H. C. Wood was appointed chairman of the committee, and the temporary officers of the meeting, Drs. Gross and Walker, were made *ex officio* members of it.

COMMUNICATIONS.

INFLAMMATION OF THE BLADDER
AND URETHRA, FROM ABNORMAL
CONDITIONS OF
THE UTERUS.BY C. W. LEIGH, M.D.,
CHICAGO.

Frequently in the examination of patients suffering from abnormal conditions of the female generative organs, such as lacerations, displacements or ruptures, we find the conditions giving rise to the greatest amount of inconvenience and suffering, are those referring to the urethra and bladder: these varying in the same individual at different times, according to the duration of this diseased condition and the causes operating.

Hyperæsthesia manifests itself by a feeling of heat and weight, which may or may not be constant; a desire to urinate often, the quantity passed at each time being small and followed by a scalding or burning sensation with vesical tenesmus. This condition may continue for an indefinite length of time without producing serious structural changes, but eventually all the above mentioned symptoms become intensified, and genuine inflammation is developed, with the accompanying aggravating phases of the same.

Often it is a matter of some difficulty to draw a line between hyperæsthesia and actual inflammation, and in such cases it is not a matter of practical importance to differentiate, the treatment of each, in such an event being very much the same. In perhaps a smaller proportion of cases, true cystitis, urethritis, or both exist, although of a type peculiar to these cases.

When there is general pelvic congestion from any cause, the bladder is quite liable to participate.

In lacerations of the cervix, ruptures of the perineum, or in any condition where the uterus is made to assume an unnatural position, it sinks lower into the pelvic cavity, and, by the pressure it exerts upon the veins, retards the proper return flow of blood from the uterus. In other words, mechanical congestion results, which may terminate in inflammation; nutrition is imperfectly performed, ulceration follows, and an unhealthy discharge takes place.

This condition gives rise to hyperæsthesia of various parts of the body, but especially

of the pelvic viscera and markedly the bladder. The mechanical pressure exerted upon the bladder by a displaced womb is not so frequent a cause in these cases as is commonly supposed.

In retroversion, manifestly there is greater pressure upon the rectum than the bladder, while the latter suffers more than the former. Yet each are excretory organs, performing their functions in a similar manner, and are identical in anatomical structure, *i.e.*, each is composed of four coats: serous, muscular, cellular, and mucus.

A very important factor to be taken into consideration, and one very frequently overlooked, consists in the unhealthy discharges from the uterus and vagina coming in contact with the meatus and urethra, acting as an irritant and causing their inflammation. Urethritis is often produced in this manner, which in turn is followed by hyperæsthesia and inflammation of the bladder. Of course these are results of a mere important lesion. The treatment should be both palliative and curative. Displacements should be corrected by properly tamponading, etc. Lacerations and ruptures should be repaired, and an operation performed for the relief of the same. In the correction of displacements and preparatory treatment for gynecological operations, the use of "antiseptic wool" is to be preferred, inasmuch as it does not pack into a hard mass, but forming a soft elastic cushion supports the uterus better than cotton does, and at the same time admits of a more perfect circulation. It can be medicated if desired, or placed in position perfectly dry. It is freed from oil and foreign substances, and rendered antiseptic by a solution of biniodide of mercury. This method of treatment has been well described by Engleman of St. Louis, and Etheridge of Chicago.

The palliative treatment consists, in addition to the above, in the employment of remedies directed to the diseased mucous membrane of the bladder and urethra, and none fulfill this purpose any better, if so well, as the preparation of hydrastis canadensis, commonly known as fluid hydrastis, a concentrated fluid without alcohol.

By the process used in the manufacture of this article, the alkaloids in their native combination are said to be retained while the resin is rejected.

Seemingly better results are obtained in these cases from the internal administration of the drug in the proportion of one to four drachms to four ounces of water, a teaspoonful four times daily, than from its local use.

In a patient recently under my treatment,

aged 28 years, who had five years previously sustained a laceration of the cervix and rupture of the perineum, presumably by the use of forceps, urethritis and cystitis followed among the results.

Surrounding the meatus was a swollen and well marked deep red zone, extremely sensitive to the touch; slight supra-pubic pressure produced quite severe pain, and with the finger in the vagina making upward pressure, it was still greater.

Introduction of the finger or speculum into the vagina, either for the purpose of examination or treatment, was always preceded by the local application of a four per cent. solution of cocaine hydrochlorate to the mucous membrane surrounding the meatus urinarius, and by the injection of several drops into the urethra. This afforded considerable relief to the patient on these occasions.

The cervix and perineum were prepared for operation by local applications, tamponading with "antiseptic wool," administration of tonics, laxatives, etc. Specially for the relief of the bladder and urethra, fluid hydrastis was prescribed, both internally and as an injection.

The patient improved quite rapidly and both operations were performed at one sitting, Dr. J. C. Pickard, of this city, and others assisting.

In a short time the generative organs recovered their normal condition and functions, but the cystitis and urethritis continued after the removal of the immediate cause.

If from any reason the internal administration of fluid hydrastis was discontinued, she became worse, but immediately improved when it was resumed.

The same was not true of the injection, although it was beneficial without doubt. Now, at the end of eight months, what appeared as the predominating factor in the case has disappeared and the patient is fully recovered. The preparation is certainly a valuable one, and seems to have a special action upon the entire urinary tract. It is especially useful in the class of cases just referred to.

—Condensed beef in tablets is being introduced into French practice under the name of *tabelettes Rousseau*. Each tablet contains 20 grammes (about 5 drachms) of beef powder, representing 80 grammes of fresh beef. According to the author, this preparation soon makes chlorotic and cachectic patients able to digest other kinds of nourishment easily. —*Am. Druggist*, Aug. 7, 1887.

INEBRIETY AND INEBRIATE HOSPITALS IN AMERICA.¹

BY T. D. CROTHERS, M.D.,
Supt. Walnut Lodge, Hartford, Conn.; Editor
Journal of Inebriety, etc.

Origin of the Movement.—In 1809, Dr. Benjamin Rush, of Philadelphia, Pa., published a work entitled "Medical Inquiries," in which he declared "that intemperance was a disease, and that hospitals for its exclusive treatment should be established in all the principal cities of the land." Similar views had been urged at different times in the past, dating from the comments of Ulpian, the Roman jurist, who wrote in the second century of the Christian era.

The honor of bringing this fact into the realm of practical science is due to Dr. J. E. Turner, a practicing physician in the state of Maine. He vitalized this idea in the organization of the first inebriate hospital in the world. In 1846, Dr. Turner became interested in this work, from an ineffectual effort to save an early friend who was an inebriate. He recognized the nature of the disease of inebriety and the need of hospital treatment, and began an enthusiastic agitation of the subject. After eight years of most persistent effort, in the face of great opposition, he succeeded in enlisting the attention of many eminent medical men, and in forming a company to build an Inebriate Hospital, with the late famous surgeon, Dr. Valentine Mott, as president. Laws were passed to give power to hold inmates, a charter was granted, and nearly ten thousand pounds subscribed for the grounds and building. Ten years later, in 1864, a magnificent building was completed and opened for patients, at Binghampton, N. Y., the pioneer hospital of the world. Later, a fire destroyed part of the building, which was soon after rebuilt. Then the board of trustees became involved in a controversy with the founder, Dr. Turner, resulting in his retirement, and placing the hospital in the care of the State. Passing into the management of politicians, its history was a series of misfortunes, until finally it was changed into a chronic insane asylum. Thus Dr. Turner, the founder, who had conceived and built this hospital, giving over a quarter of a century of time and effort, and his own personal fortune, shared the fate of all reformers and benefactors of the world, in the obloquy and disgrace of being driven away from the creation of his own genius.

¹ From an Address delivered before the International Congress on Inebriety in London, England.

Thus the pioneers and leaders of all great truths of science are martyrs in their day and generation.

The enthusiasm which at first centered about Binghampton Hospital reacted, and the moralists and temperance advocates, who from the first had opposed this movement as an "infidel work" to diminish human responsibility, used every means to spread the idea of failure and condemn other efforts in this direction. But a great fact had been recognized, and its practical character had taken deep root in the public mind. The birth of the Binghampton Hospital was followed by the organization of over a dozen different hospitals for this work in different parts of the country, some of which are still in existence, doing grand work.

The Hospitals for Inebriates of to-day.—Notwithstanding the misfortunes of the first hospital and its founder, a large number of similar places have been organized and managed with success. As in all new enterprises, many of these hospitals must suffer from non-expert management, and be organized on some theory of the nature and treatment of inebriety not founded in correct study and experience. After a time they are abandoned, or changed to homes for nervous and insane cases. Over fifty different hospitals for inebriates have been established in America. More than thirty of this number are in successful operation; the others have changed into insane asylums, water cures, etc. Three large buildings or institutions are practically "faith cures," where all physical remedies and means are ignored. Several asylums are called homes for nervous people, to conceal the real cause, and thus protect the patients from the supposed stigma of inebriety. Others are literally lodging houses, where the inmates can remain a few days and recover from the effects of spirits. Several places make a specialty of opium cases; in some the treatment is often empirical. In only a few of these hospitals is inebriety studied and treated on a scientific basis. The others are passing through the ordeal of "elimination and survival of the fittest," incident to every new advance of science. In many of the States large public hospitals are projected, and are awaiting pecuniary aid from the State or from other sources.

Inmates of Hospitals, and the Cures.—Not less than two thousand inebriates are under treatment in hospitals in America. Over a thousand of this number are in special hospitals. They represent most largely the incurable cases; persons who have tried every means found in the pledge, prayer, and by

moral suasion, and exhausted every resource of home and friends, and come as a last resort, expecting extraordinary change and cure. They have been victims of this disease from five to thirty years, and present the most complex and varied degrees of physical and mental degeneration. Yet, notwithstanding this fact, the experience of the few scientific hospitals in the results of treatment is exceedingly promising. Statistics of over three thousand cases, which have been under treatment at different hospitals, indicate nearly forty per cent. restored and temperate after a period of six to eight years from the time of discharge from the hospital. The best authorities unite in considering thirty-five per cent. of all who remain under treatment one year or more as permanently restored. In view of the chronic character of these cases, and the imperfect means of treatment, these statistics are encouraging, and indicate great possibilities in the future from a better knowledge and control of these cases.

Legal Control of Inebriates.—The legal control of the inebriates in America, and legislation, are very imperfect. In Connecticut, the best laws are in force, giving power over inebriates to voluntarily commit themselves, or be committed by their friends, without the formality of appearing before a judge or court. In other States they are committed to asylums in about the same way as the insane are. In the hospitals they are controlled legally the same as the insane, only with more difficulty, and the constant intrusion of disputed questions of authority which cannot be settled. Nearly all the leading hospitals have special powers of control, which they exercise with caution in most cases. But generally both legislation and legal authority are not far ahead of public sentiment, and hospital managers are unwilling to go beyond this. Most of the hospitals have power to control patients a certain specified time, agreed upon when admitted to the hospital.

Hospitals organized by State and private means.—Most of the inebriate hospitals in America are private and corporate organizations, which receive, from time to time, State aid. Some of them have endowments, such as free beds, or incomes from estates, or are given so much of the license money. Others depend upon the income from patients, private donation, and charities generally. Very few paupers or indigent poor are received in any of these hospitals. This class appear in the "lodging" and "faith cure" places. The State of Con-

necticut has projected a workhouse hospital for the criminal class of these cases where the commitment is for three years, but want of State aid has prevented practical work so far. In three other States similar projects for the pauper inebriates have been organized, but for various reasons have not gone into operation.

Literature of the Subject.—The exact scientific study of inebriety has revealed facts and conclusions which have aroused bitter controversy, from those who should have been first to welcome its truths.

A large number of so called reformers have been from the first denouncers of the disease theory, but unwittingly they have greatly helped on the work by controversy and agitation. In 1870, an association was formed of persons who were connected with inebriate asylums, or interested in the subject, called the American Association for the Cure of Inebriates. This Association has met yearly and semi-yearly ever since, and its papers and transactions comprise the first permanent literature on this subject. In 1877, the *Journal of Inebriety* was issued as the organ of this association, and from that time has been the medium through which most of the literature of the subject from America has been presented. Inebriety, and its curability in special hospitals, has been the cardinal principle of this Association, which it demonstrated and maintained with increasing vigor. Discussing exclusively the physical side of this subject, amid difficulties which only pioneers in a new field have to contend with, the foundation of a scientific literature has been laid which will be historic to future students of this subject. This Association and its journal are great silent powers, crystallizing and marshalling the many facts constantly appearing from a study of these cases. Already two members of this Association, Dr. Parrish and Dr. Wright, have published works on inebriety that mark the beginning of a "new era," and have given great impetus to its scientific study.

Inebriety in America.—It is evident that inebriety in America partakes largely of the intensity of life and living so noticeable to foreigners. It is more precipitate, maniacal, and rapid in its progress; stronger spirits are used, insanity follows more quickly, and all forms of degeneration appear.² The life of an inebriate, dating from the time of the first intoxi-

cation, is much shorter than in other countries. The victim seems to plunge into every form of excitement, such as speculating, politics, religious and temperance agitations, and every new movement which attracts attention. Public sentiment seems to seek relief more for the inebriates who are active brain and muscle workers, but has not advanced far enough to be much interested in the pauper and criminal classes. It is the cure and treatment of these cases, who seem to have power to help themselves, the men of genius, education, property and influence, that are rousing interest in the subject, and creating a demand for help, which quacks and charlatans are rushing forward to meet. Eleven different specific remedies are advertised as certain cures for inebriety, and the intensity and impulsiveness of the various moral movements for this end are psychological wonders of the age.

Some Conclusions.—The history of the inebriate asylum movement in America is only a repetition of every real advance in science, passing three regular stages of growth: first, agitation; then opposition; and finally acceptance. It is now in the first and second stages. The students of science who have examined the facts find the disease of inebriety and its curability in special hospitals supported by such an array of evidence as to demand its full acceptance. The opponents, who have misunderstood the subject, are still agitating and opposing this view. Inebriate hospitals in America are rapidly merging into well-appointed, thoroughly scientific places for the study and cure of the inebriate. Empiric institutions, managers, and methods of treatment still exist, but in them all there are most hopeful indications of a larger and more accurate work. A great undercurrent of public sentiment is not content with only the moral remedies urged by agitations; they are turning to physicians and scientists, with a growing conviction that from this side the true remedy for this evil will be found. The few pioneer workers grope along the borders of this "new continent" of facts like the "old Northman" on the shores of New England, conscious that a great, new, unknown world of laws and forces stretch out before them. The demand in America, as elsewhere, is for well established facts concerning inebriety and its treatment in special hospitals,—facts and conclusions reached by competent observers, and based on data beyond question. The subject must be studied, independent of all opinions and metaphysical theories, before its cure or prevention will be a practical

² Heredity is more positive and certain, both from inebriety and the many complex nerve diseases. Neurasthenia and all forms of nerve strains and drains are very active factors in the causation.

reality. Legal power over the inebriate long enough to make a possible cure, and means to organize and sustain hospitals for this purpose, are demanded everywhere to-day. These wants are being rapidly recognized, and all investigation sustains the conviction that the time is not far away when the inebriate will be taken from his home and on the street, and quarantined in special hospitals, the same as if suffering from an infectious disease. If an incurable, he will be housed and made self supporting for life. A united sentiment in this direction will be felt all along the line of progress and civilization.

EGYPTIAN TAMARIND FOR HEMORRHOIDS.

BY J. C. BROBST, M.D.,

LITITZ, PENNA.

Very recently my attention has been attracted to the Egyptian Tamarind Flower, a blossom that may be considered a most excellent specific for bleeding hemorrhoids or piles. In my practice I have had the most extraordinary results from its positive curative powers, and especially has this been so in cases deemed incurable and given up by other physicians. Prior to using it, I was in the habit of employing injections of turpentine, perchloride of iron, ointments of nutgall, oxide of zinc, rosemary, acetate of lead, and numerous other astringents; and while these may all give temporary relief, the actual or net result is irritating rather than soothing, as most certainly are the effects of the tamarind flower. I have noticed, after giving my patients three or four wineglassfuls of the decoction, that they were instantly relieved of the persistent itching and burning sensation, while the excrement seemed to be materially altered by it. I have also tried "tamarind" in nervous debilitated women, with like good results, especially when their sickness has been complicated with costiveness and loss of appetite. In these cases tonic properties were plainly discernable, and tamarind flower may in my judgment be well considered a "tonic laxative."

In Dr. W. H. Howell's essay, read before the State Society at Scranton, Pa., he speaks of tamarind flower in decoction as one of the best laxative nervines. The flower also makes an excellent face-wash, and for the removal of freckles and pimples it cannot be excelled.

In this present day, when both the profession and laity are fully aware of the fact that the physician is by no means the only resource

and medium of alleviating and curing diseases, I should like to have it placed on record that for the diseases mentioned herein, I believe the tamarind flower possesses more virtue than any other drug.

OBSTETRIC PRACTICE—CASES.

BY STANLEY M. WARD, M.D.,

ELLENVILLE, N. Y.

Breech Presentation with Hydrocephalic Head.

Most authors, so far as I can learn, agree with Scanzoni, in stating that about 20 per cent. of all hydrocephalic children are born with some or part of the body presenting beside the head. The patient, whose case I am about to narrate, is a German woman, healthy, well-formed, and was 23 years of age, pregnant with her third child. At the age of 20 she was delivered of a hydrocephalic child, breech presentation, after a tedious labor. I did not attend her and cannot furnish details. Her second child was born in about a year, was well-formed, and her labor was normal, though somewhat slow. During her third pregnancy I was consulted, as she expressed her opinion that the child would be malformed and present improperly. I examined her by the vagina and externally, but could get no information. She was taken in labor about noon. On reaching the house and making an examination, I was unable to make out the presentations at first; soon, however, I detected a breech and feared that I also should have a hydrocephalic head, in the light of her previous history. Uterine contractions were not strong, and expulsion took place slowly. In due time I delivered the feet, arms and part of the body of the child, and hoped then to be able to apply the forceps to the after-coming head. This was found to be impossible. The child was very large, and nearly completely filled the vulvar aperture. Her pains now ceased, and by the time my consultant, Dr. J. J. Ward, reached the house, the child was dead. We attempted delivery by the blunt hook, having thoroughly satisfied ourselves of the death of the child, and the presence of hydrocephalus. We tried the hook first in the jaw and in both eyes afterwards, vainly; the bony walls of the eye-sockets broke down completely, and we tore the jaw down. The patient would not allow anesthetics to be used, which, of course, compelled us to work at a disadvantage. Dr. B. R. Bevier now joined us. He attempted to apply forceps to the body of the child, but failed. I now

suggested a procedure of which then I had never heard, but which I since have seen recommended by some authorities, viz., decapitation as high up as possible, and forceps to the head remaining in the uterus, or failing to apply them, to perforate. This plan was objected to, and I yielded. After many attempts and failures I finally succeeded in getting my hand, not a large one, within the uterus and around the child's head. I had provided myself previous to introducing the hand with a bistoury well protected so that only the point projected; with this a hole was cut into the head large enough to permit of its enlargement with the fingers and it was soon made large enough to admit the hook; the other physicians performed traction on the legs and body of the child, and I managed the hook, and thus we succeeded in delivering her about midnight. As before noted no anæsthetic was allowed. The woman's getting up was not delayed. Her breasts she managed herself in a manner peculiar to German women in this locality, viz.: applied camphor, gum and lard thoroughly, and then bind a wide piece of muslin as tightly around them as possible. I can vouch for the usefulness of this proceeding.

This woman has since been twice pregnant, aborted once at four months, and had a living well formed child at full term in April last. This labor was normal, but tedious, like the second one. Should I ever be so unfortunate as to find this state of affairs again, I intend trying the method suggested by Tarnier, namely, to open the spinal canal as high up as may be, and by means of a catheter inserted through this opening into the brain cavity, to withdraw the fluid. Something of this kind suggested itself to both the consultants and me, when we were considering this case, but neither of us knew then of the success achieved by the distinguished French teacher.

Puerperal Septicæmia.

During the month of May, 1886, I had two consecutive cases of child-bed fever. Both made good recoveries. These were the only cases I saw either in my own practice or in that of my father, Dr. J. J. Ward, although we attended nearly seventy-five women in confinement between that date and the following April. On the 13th of April, 1887, I was asked by Dr. J. J. Ward to see with him Mrs. R. H. B., whom he had attended in confinement four days previous. Her labor had been normal and easy for a primipara. The placenta had been expelled naturally and without any in-

terference, and the uterus had contracted well. Her nurse had had a carbuncle on the back of her neck a week or two previous to the confinement, but as it had healed nicely, and she had been but little in the lying-in chamber, no danger was apprehended. The patient had done well until the evening of the third day after confinement, when she was attacked with a heavy chill, followed by aching head and limbs, with the usual attendants of fever. When I saw her she had photophobia and headache, yet seemed bright and cheerful. The external genitals looked healthy, but the lochial discharge was scanty and somewhat offensive, and the vagina was hot. My hand on withdrawal contained strings of a nasty, dark looking material. There was no secretion of milk. Notwithstanding the fact that nearly a drachm of quinine had been taken in divided doses since the first appearance of sepsis, and that vaginal injections of hot carbolyzed water had been used, probably in a perfunctory way, her temperature in the axilla was $105\frac{1}{2}^{\circ}$, and her pulse 120. It was between three and four o'clock P.M. The vaginal injections were ordered every four hours, to be used thoroughly, and ten grains of antipyrine were also given; the nurse was also ordered to sponge her thoroughly and to repeat it when the body heat seemed excessive. At 8 P.M. she was no better. She slept badly during the night. At 3 P.M., the next day, the local symptoms were aggravated; temperature 105° . She was given a scruple of antipyrine, and sublimate injections replaced the carbolyzed water. Affairs went from bad to worse, and at 9 P.M., when the attending physician and myself made our evening visit, he suggested that I take charge of the patient in the double capacity of nurse and physician. I therefore stayed in the house the entire night, administered medicine and used the injections. For nearly a week I lived in her house, and left her for but a few hours at a time. Nearly every unfavorable symptom that one might think of, except vomiting, we were called to combat,—diarrhœa, checked finally by suppositories of nitrate of silver and opium; delirium; excessive interior hemorrhage ending in a state of collapse, so that all one night we stood by her bedside using hot applications to the extremities, with hypodermics of brandy and ergot; abdominal pain and tenderness, together with excessive and almost uncontrollable hysterical symptoms—she had them all. Locally, the vagina became one festering mass. The sides and as far back as I could see were covered with a deposit that looked, possibly

was, diphtheritic; pus was formed in abundance and flowed freely out of the vulva; excoriations and erosions of the vulva occurred, and at times hemorrhage from this part took place. On the fourteenth and fifteenth days after her confinement, following severe uterine pain, she passed two masses about the size of a hen's egg from the vagina, which upon being opened emitted a sickening stench. These masses were either decayed and putrefying blood or else, as I then thought, parts of the degenerated endometrium.

The woman finally recovered and was around the house by the middle of May. A word or two as to the treatment she received. There are many fine spun theories which seem impregnable and satisfactory until put into practice, while on the contrary many procedures which are found to answer all the requisites in practice are hard to defend by pure reasoning. I may confess that, having consulted many authorities both ancient and modern regarding the fever of child-bed, I can advance no theory either as to its cause or treatment that could not be easily controverted by a believer or unbeliever in its septic causation; nevertheless I am no more certain of my own existence than I am of the fact that this patient would have succumbed under any less active treatment than was instituted. This was above all antiseptic. For several days she received vaginal injections every three to four hours night and day of either corrosive sublimate one to three to four thousand, or, after diarrhoea suspended, solution of chlorinated soda, diluted one-half. Of uterine irrigations she received but two, both of the chlorinated soda. Beside this her vagina was packed from three to four times daily with boracised cotton, and the external parts freely sprinkled with a mixture, half-and-half, of iodoform and boracic acid. Over the vulva was placed a pad of iodoform. Antipyrine proved its great value in this case, as I have seen it do many times before and since. A scruple, administered in brandy and water, would, within an hour, reduce the temperature from two to three degrees without any symptoms of collapse; and this with stimulants, chiefly alcoholic, was all the medication she received save as special symptoms demanded it.

'Puerperal Convulsions.'

On July 3d, 1886, saw Mrs. S., aged 18, primipara and far advanced in pregnancy, in a convulsion. The time was one P. M. Gave a half grain of morphine hypodermically. Could get no history, as the woman was unconscious and the friends around knew

nothing except that they had found her on the floor in a fit about a half-hour before. Having made an engagement prior to my seeing this patient, I told the family that I would be back in three hours, and if she had another convulsion to call another physician. Returned about a quarter before four and found Dr. Eastgate in attendance. The patient had rested quietly for nearly an hour after I left her, and then had a convulsion. The doctor had been in the house but a few minutes when I arrived, and requested me to take charge of the case with him. While discussing various plans of treatment, another convulsion occurred. Dr. Eastgate administered chloroform immediately and I examined the uterus by the vagina. The os was slightly dilated. We inserted a catheter into it, and as soon as the convulsion ceased made ineffectual attempts at venesection. In ten minutes another convulsion took place, and chloroform was again resorted to. As soon as possible another half grain of morphia was given hypodermically and a half drachm of chloral administered by the rectum. She did not have another convulsion until five o'clock. It was quite severe, notwithstanding the fact that chloroform had been administered all through the interval. Another injection of chloral, twenty grains, was administered. Chloroform cautiously continued. An examination of the uterus disclosed the fact that the child was making good headway. The membranes were protruding. At six o'clock she had another convulsion. It was not so hard as the others. Dr. Eastgate now left me to meet other engagements. At seven o'clock another convulsion occurred. I now ruptured the membranes and applied the forceps high up, delivering a large female child. The patient fell asleep, and after watching her an hour and observing no return of the convulsions, left her until the next morning. Found her at that time sensible and entirely ignorant of having given birth to a child until it was placed in her arms. This woman was perfectly unconscious from one o'clock P. M., July 3d, until four o'clock the succeeding morning.

Case II.—July 28th, 1886, saw Lena W., unmarried, pregnant with her first child. Dilatation was slow, and about two in the afternoon, having given morphine and chloral without effect, commenced administering chloroform. In fifteen minutes thereafter she had a convulsion. Dr. J. J. Ward and a fresh supply of chloroform were sent for. Before he reached me another convulsion took place. We administered chloroform then as

required. The convulsions occurred very rapidly, and the os uteri seemed very rigid. As soon as possible, and after she had had six convulsions, the forceps were applied and the child safely delivered. Dr. J. J. Ward now left me, and I was preparing to go also, when another convulsion, the hardest of any, occurred. I immediately resorted to the chloroform again and kept her under its influence one hour, then gave a quarter of a grain of morphine hypodermically and left her. Saw her at nine P. M. She was in a dazed condition; face bloated. Gave twenty grains of chloral by the mouth. In the morning she was much the same, though she had slept well during the night. Gave two drops of croton oil, with instructions to repeat in six hours if necessary. At four P. M., found her better. The oil had operated, she had passed urine and was perfectly conscious. She then for the first time realized that her child was born.

ON THE CONJUGAL QUESTION.

BY JANET E. RUNTZ-REES.

In the lower animals, where the balance of sexual relation is perfect, passion is frequently greatest in the female. In the generative relation of man this is less often the case, and where it is recognized as existing, it is rarely insisted upon. The reason of this fact is obvious. Among semi-barbarous people the male is inordinately jealous of the purity of parentage; he selects his wife, less from attraction or motives of affection than as the future mother of his children, and as affording reliable soil for his generative seed, and seeks more ardent embraces in the concubine. Hence, in the evolution of race, passion in the male is increased in transmission, while in the female a corresponding repression of natural instincts results. Now, this fact is attended with far reaching and injurious consequences. Nature is cruel; she demands perfection; and inflicts suffering upon all that fall short of her standard. The sexual relation, as nature intends it, includes perfect physical adaptation and absolute mental harmony. The evil resulting from imperfect physical adaptation is more serious for the participants; that arising from mental disagreement involves the healthful morality of the offspring.

Physical inharmony arises from one of two causes: either the male is precipitate in ex-

pression, and, if selfish or wanting in generosity, ignores the fact that he has aroused desire in his companion without gratifying or awaiting the expression of its appetite; or the female is the more ardent of the two and her lover is irritated by her anticipation of his relief. Perfect physical adaptation means equal ardor of anticipation on either side, mutual enjoyment of the mechanism of the sexual act, and simultaneous expression. In every case where union is less perfect, nature inflicts physical suffering on one or both of the participants. Coitus, in such cases, soon becomes mechanical to the male—mere appetite; and wearisome to the female. In her case, inharmony in physical adaptation is followed by one of two results: either she becomes indifferent and her non-response is followed by induration, congestion of the ovaries, partial paralysis of the generative organs, arrested menstruation, and incipient abscess or cancer; or the irritation and constant mechanical action of the sexual parts without corresponding relief, induces inflammation and a morbid *abstract* appetite, which bears no relation to affection, and is indifferent as to the individual; is, in short, depraved passion, and leads to infidelity, which is the open door to prostitution, and to nymphomania and insanity.

Mental harmony in the sexual relation means: ardent mutual love; absolute sympathy; unified expression. Where physical harmony exists, the gratification of desire results in healthful, true marriage; where both physical and mental harmony accompany the union of the sexes, a perfect marriage is consummated. The offspring of the true marriage is healthful and physically robust, the child of the consummation of the *perfect* marriage, in which physical adaptation is seconded by mental harmony, is—heaven inspired genius.

Every sexual union, of whatever nature, lawful or illicit, that does not include one or both of these harmonious relations, is prostitution, the mere gratification of unhallowed lust, to be followed by the unerring Nemesis of outraged nature, by suffering to the third—aye, and fourth generation.

—Dr. Harris thinks that if Macduff told the truth when he said: "I am even he that the wizards have told thee of, who was never born of any mother, but ripped out of her womb"—he is much more likely to have been delivered by a horn or sword than by the knife of a surgeon.

SOCIETY REPORTS.

NEW YORK PATHOLOGICAL
SOCIETY.*Stated Meeting, October 28, 1887.*

The President, T. MITCHELL PRUDDEN,
M.D., in the chair.

Report of the Committee on Microscopy.

Incrustation of the Tube Employed in Intubation of the Larynx.

At a recent meeting of the Society, Dr. Boldt presented a tube employed for the relief of laryngeal stenosis, which was coated with some kind of deposit. The committee on microscopy reported that the incrustation was limited almost exclusively to the exposed head of the tube, and was composed of the carbonate of lime. There was slight roughening of this portion of the tube, and the inference was that corrosive sublimate, used in the treatment, had formed an amalgam with the gold plating, after which the carbonate of lime was deposited,

DR. NORTHRUP said this raised a new point in the history of intubation. He had himself had a case in which the tube was slightly roughened after the use of corrosive sublimate. The patient's voice returned slowly after the tube was withdrawn, and perhaps this roughened condition of the tube would account for that fact.

Diverticula of the Mucous Membrane of the Bladder, with Diapedesis.

At the last meeting of the Society, Dr. Northrup had presented the bladder of a man who as many as half a dozen times had passed clear blood with the urine. At the autopsy, some enlargement of the prostate was found. The walls of the bladder were slightly thickened, and in the mucous membrane were apparently round, punched out ulcers. The bottom of the ulcers appeared red, as if in a state of ulceration. The microscopical examination, however, showed the mucous membrane intact, and that the depressions were only diverticula. The hemorrhage was accounted for by Dr. Prudden on the supposition that the flow of blood was here interfered with, resulting in diapedesis. This case had been of further interest in the fact that there was congenital absence of one kidney, and carcinoma of the gall bladder.

Dr. Northrup presented (for a candidate) a specimen of kyphosis, with the history.

Uterine Hemorrhage Some Years After the Menopause.

DR. A. P. DUDLEY related the case of a woman, who thirteen years after the menopause suffered from uterine hemorrhage, attributed by her physician to a fibroid. Examination failed to reveal a fibroid or any condition to account for the hemorrhage. The cervix being dilated, the mucous membrane was scraped, and a considerable quantity of a material resembling myxoma or polypus was removed. It was believed not to be malignant.

Hæmatoma of the Ovary.

Dr. Dudley also presented an ovary, the seat of hæmatoma, removed from a girl twenty-two years of age, who had been under his treatment for a year for local pain referred to the region of the ovary. Treatment by hot water, iodine, blisters, etc., failing, he finally resorted to laparotomy. The hæmatoma occupied the greater part of the organ. The patient was now convalescent, and had suffered no more pain.

DR. CARPENTER related a case the history of which was almost identical with that of Dr. Dudley's first patient.

Tubercular Meningitis.

DR. L. E. HOLT presented the brain of a child four and a half years old, the seat of tubercular meningitis. The child had healthy parents, but tubercular grandparents. The symptoms of meningitis were well marked, but neither before nor after death was there evidence of pulmonary tuberculosis found. A few tubercles were present in the bronchial glands. A point of some interest was the presence of a cheesy focus of considerable size at the lower extremity of the third frontal convolution, although during life there had been no disturbance of speech. There were scattering tubercles in the spleen and liver.

Acute Strangulated Hernia, Complicated by Acute Hydrocele.

DR. W. H. PORTER presented a portion of the intestine with the following history of the case: A man, between thirty and forty years of age, developed on last Friday night active symptoms of strangulated hernia. He had never before had any tumor in the inguinal region or scrotum. When a physician was called he found a large painful tumor in the right inguinal region, and tumefaction of the right side of the scrotum. He instituted taxis and caused rapid disappearance of the scrotal tumor, and, as he supposed, disappearance of the strangulated hernia.

But the symptoms of strangulation continuing, he made repeated attempts at taxis until Sunday night, when the patient became moribund and was transferred to a hospital. The surgeon in charge thought that at this time an operation would only hasten death, and it was not performed. At the autopsy there was no tumor in the scrotal or inguinal region. It was found that the sac of the hydrocele had ruptured and the fluid (about a pint of bloody serum) had escaped into the peritoneal cavity. There was no peritonitis. A knuckle of intestine was strangulated at the internal ring, but the gut was in fair condition.

Multiple Diverticula of the Bladder; Vesical Calculi.

DR. IRA VAN GIESON presented a bladder, the seat of a number of small diverticula of the mucosa, and of one larger one containing a number of small calculi. The case was interesting as illustrating how larger diverticuli might be formed from smaller, viz., by the deposit successively of small calculi in its interior. A small aperture led from the diverticuli to the interior of the bladder. The pelvis of one of the kidneys contained a number of calculi the size of a pea. There had been no clinical history referable to the bladder.

EDITORIAL DEPARTMENT.

PERISCOPE.

Infectious Tonsillitis.

In a review of this subject in *Le Concours Médical*, September 17, 1887, O. Le Gendre says: In 1880, Professor Ch. Bouchard taught that acute tonsillitis ought to be considered an infectious disease. He based his opinion upon seven observations. He had four times seen tonsillitis accompanied with an infectious nephritis, the urine being loaded with bacteria. In one case, the nephritis, which had seemed to get well at the same time as the tonsillitis, relapsed at the end of the twelfth day. In this attack, typhoid symptoms showed themselves, and the patient died. In another case, in which the nephritis appeared eight days after the outbreak of the attack of tonsillitis, the former became chronic. M. Bouchard also saw a father and daughter attacked simultaneously with sore throat, both of them presenting a transient albuminuria with bacteria in the urine. He has cited two observations in which, on the decline of acute tonsillitis, there appeared a pseudo-rheumatism involving especially the periarticular fibrous tissues of the joints of the fingers. In a case of phlegmonous tonsillitis, he has demonstrated, in the pus taken from the openings in the abscess of the tonsil, an enormous quantity of short and slender bacilli.

It cannot be denied that cold and dampness play a part in the etiology of tonsillitis, but it is a part similar to that which is properly ascribed to them in pneumonia. Cold permits the microbes, which are carried by the liquids of the mouth and by the air and deposited upon the tonsils, to invade the crypts, to penetrate more deeply, and to in-

fect the whole organism. If the organism is in a bad condition already, if the patient is an overworked, ill-nourished alcoholic, the infection will have a greater hold upon him. In such subjects the infectious state is so marked that every physician, even if not disposed to favor parasitic notions, will be obliged to recognize the general disease.

M. Dubousquet-Laborderie, of St. Ouen, has recently insisted upon the gravity of amygdalitis developing in this way. Chills, a violent fever, anorexia and headache open the scene as in every acute tonsillitis; but, besides, the patient complains of extreme backache, which sometimes is unbearable; swallowing is painful and the throat hyperæsthetic; nevertheless, one only finds redness and some swelling of the mucous membrane; no exudate, either herpetic or diphtheritic. However, there is more or less engorgement of the submaxillary glands. Some complications analogous to those of diseases which are most positively infectious can be pointed out: typhoid symptoms, vomiting, fetid diarrhœa, albuminuria, with epithelial debris and bacteria in the urine, pseudo-rheumatic joint-diseases, even to orchitis and ovaritis, which Joal has noted, as they are seen in mumps.

Just here may be related a very curious observation by Professor Henrot, of Rheims, who was by turns spectator, actor and victim in the pathological drama.

Dr. Henrot was called on May 1, 1886, to see a patient who had passed three or four days in Paris occupied with business affairs. He had been subjected to a draught, and in the evening, on retiring, he was seized with a sharp pain in the throat, which prevented him from sleeping. At the time of his first

visit, which occurred in the morning, there was only redness of the arches of the palate and of the left tonsil. For some time the patient had been occupied with business that required considerable thought, and had become nervous and impressionable, although the pain of which he complained seemed exaggerated, for the redness was not very intense and did not cover a large surface. In the evening, there was some œdema of the uvula. On May 2d, the uvula was swollen to the size of the thumb, but the rest of the mouth not especially swollen. The swelling extended so as to involve the tongue and prevent the swallowing of even a drop of water. The larynx remained unaffected. Finally, the neck also became swollen and the lower jaw immovable. M. Verneuil was called in consultation, and used the thermo-cautery. No pus was found. On the 5th of May, the patient was somewhat easier, but the bowels were obstinately constipated, and very little urine had been passed since the beginning of the disease. Profound adynamia ensued some hours later, and on the 6th of May the patient died in coma.

MM. Henrot and Verneuil regarded the disease at the beginning as due to the poison of anthrax, but M. Dubousquet-Laborde considered it as analogous to several of his observations in infectious tonsillities.

M. Henrot himself was taken sick in a short time afterwards with an attack similar to the one his patient suffered from; and after a very sharp illness, lasting three or four days, recovered.

Renal Ballottement.

Dr. Charles Tisné, in the *Annales Médico-Chirurgicales*, August 1, 1887, reviews a paper by Dr. Clado, which was published in *Bulletin Médical*, July 27, 1887. The following directions are given for practicing renal ballottement: Let the patient lie horizontally, without flexing his thighs. Then insert the right hand into the space between the ribs and the ilium, and make at first gentle concussions. If pain is occasioned, the exploration ought to be made very gently. The left hand resting upon the abdominal wall exerts too gentle a pressure to render the kidney immovable, but feels the movements of the kidney and explores its wall. As the result of experiments made upon a healthy man and upon the cadaver, M. Clado concludes that perception of the shock of the kidney clearly indicates an increase in its volume. Ballottement, as might be expected, is easy in thin subjects and difficult in fat ones.

Moreover, the pain in acute affections of the kidney, and the contraction of the abdominal muscles which accompanies it, absolutely prevent its successful employment.

If it is true that ballottement indicates an increase in the volume, it ought to disappear when the kidney returns to its normal state. This is actually found to be the case in the congestion which accompanies the painful attacks of pyelonephritis. If the size of the kidney is great enough to reach the abdominal walls, ballottement disappears.

M. Guyon has investigated this sign in a great number of surgical affections, and especially in tumors of the kidney. Its importance is extreme from an operative point of view, for the sooner ablation is performed, the less is the danger. It is evident that a study of the patient will alone reveal the nature of the disease.

The production of renal ballottement bears no resemblance to foetal ballottement, because, in addition to normal adhesions, there can exist some pathological adhesions without which ballottement ceases to exist. Simple palpation does not suffice, because the kidney, but little increased in size and fixed posteriorly, does not extend beyond the verge of the psoas and of the crest of the ilium, while, by this procedure of M. Guyon, the kidney is driven forwards and outwards from its seat by the exploring finger.

Salol.

Seifert states in the *Centralblatt f. klin. Med.*, No. 14, 1887, that he has employed salol as a mouth-wash and gargle with very good results in different ulcerative processes in the mouth. He makes a six per cent. solution in alcohol, and adds a teaspoonful of this to a glass of warm water. The drug was not only well borne, but also relieved the disease much more quickly than the treatment with chlorate of potash or salicylic acid. The author calls particular attention to a case of chronic diphtheria which for three weeks had resisted every treatment. After using the salol gargle for three days, the dense, tenaciously adherent membrane became loosened, and did not return.

Insufflations of salol in fetid atrophic rhinitis, in the after-treatment of operations upon the nose, and in tuberculous ulcerations of the larynx, gave less favorable results. The drug acts as an antiseptic and is not irritating, but does not cling to the mucous membrane, and is therefore unsuitable for the purposes just named.—*Centralblatt f. d. med. Wissensch.*, September 10, 1887.

Phlebitis in Gonorrhœal Rheumatism.

In reviewing this thesis of Charles Martel's, Paris, 1887, Pichevin says: It is admitted at the present time that gonorrhœa, which is a local affection at the outset, can produce a general infection of the body by the introduction of the gonococcus into the circulation. This diffuse infection can manifest itself by localizations appearing at a distance, in the eyes, articulations, heart and nerves. Martel has undertaken the task of throwing light upon some of the more rare and less recognized manifestations of the infectious state created by the gonococcus. The purpose of this inaugural thesis is to prove the microbial nature of certain inflammations of the veins arising in the course of gonorrhœa.

After stating that, unfortunately, the observations collected by the author are not all absolutely convincing, and endorsing Martel's words that a small number of facts proves nothing, Pichevin expresses the opinion that in affirming the microbial nature of phlebitis there ought to be presented conclusive microscopic, anatomical, and experimental proof.—*Progrès Médical*, August 27, 1887.

New Way to Use Iodine as a Disinfectant.

In the *Med. Press and Circular*, October 5, 1887, Drs. Casson and Brownen give the following original method of developing the vapor of iodine: The deodorizing properties of iodine have been long known, and although it has for many years been employed as a deodorizer in the cancer wards of the Middlesex Hospital, and probably in many other similar institutions, its employment as a general disinfectant has been greatly lessened, owing to the difficulties experienced in its regular and gradual vaporization. Combined, however, with salicylic acid they find that it can be readily and permanently incorporated with fats, paraffins, or wax, and when candles made from these hydrocarbons thus treated are ignited, iodine and phenol are evolved in a gaseous vaporized form. The phenol is produced by the decomposition of the salicylic acid, and its amount varies according to the temperature or rate of the combustion. Its presence may be verified by passing the vapors of the combustion through dilute nitric acid, and thus producing trinitrophenol or picric acid. But where the combustion is rapid and complete, the phenol is entirely destroyed, as all other organic materials, such as eucalyptus, which

has been suggested for somewhat similar treatment, must necessarily be. It is not so, however, with regard to the iodine. Being *inorganic*, it is wholly volatilized and thrown out as vapor into the surrounding atmosphere, but it is in no sense destroyed. Its presence in the gaseous products of the combustion may be demonstrated by passing them through a solution of starch, or along a tube moistened with starch mucilage. In either case the iodide of starch is speedily produced, and may be recognized by the usual tests. A very faint odor of iodine may be detected when these candles have been burnt in quantity in a close atmosphere; but this is never unpleasant, or in the least degree irritating to breathe; indeed, in several cases of asthma, spasmodic cough, and "hay catarrh," the patients have experienced great relief from the iodine vapor thus liberated. As a deodorizer its action is most marked; the smell of tobacco smoke is quickly and entirely destroyed by the combustion of these candles in the smoking room. The air of stuffy rooms and smelling closets may be rapidly purified by the same means. The odor of sulphuretted hydrogen and of ammoniacal air from a close stable have been very speedily and completely discharged by contact with the same vapor.

They are continuing experiments with regard to a similar treatment of oils for burning in lamps, whereby they hope to be able to furnish means of disinfecting on even a larger scale.

Asthma Crystals Without Asthma.

Dr. Pfuhl, of Hamburg, has reported in the *Deutsche Militärärztl. Zeitschr.*, the case of a private soldier, who was subject to violent attacks of chronic bronchial catarrh, for which he had to be brought to the hospital. In his sputum was found an enormous quantity of the crystals which Leyden has described, and which he believes to be the cause of bronchial asthma; but the man never showed a sign of asthmatic trouble. The constant association of these crystals with lixiviated, shrunken or granular red-blood corpuscles, which had undergone disintegration, has induced Pfuhl to think that the origin of the crystals depends upon the product of the destruction of the cell elements of the blood, and of these, probably upon the albuminate of the red blood corpuscles.

Schreiner has demonstrated that these crystals are phosphates of an organic base. He has also observed that sputum containing derivatives of its base has an intense odor, like fresh human semen. This odor was

present in Pfuhl's patient, and he thinks that this base can be found in different affections of the lungs, and that under some circumstances asthma crystals are found associated with it.

The above case cannot set aside the rule that Leyden's crystals are the characteristic sign of asthma; it is an exception which proves the rule. Pfuhl has during five years investigated the sputa of 855 patients with disease of the lungs at the garrison hospital, but only in this particular case under discussion were crystals demonstrated.—*Deutsche Medizinal-Zeitung*, Sept. 22, 1887.

Post-Rectal Dermoid Cyst.

Dr. von Biernacki describes in a thesis quoted in the *Centralblatt für Gynäkologie*, No. 39, 1887, a remarkable case which occurred in Professor Guesserow's wards. A post rectal tumor was diagnosed, and during labor its nature was made evident by tapping, whereby nearly a pint and a half of hair and greasy material escaped. Notwithstanding the consequent diminution in bulk of the growth, it still remained such an impediment to labor that perforation was necessary. Convalescence was retarded by supuration of the cavity of the cyst. Notwithstanding free incisions, pus with a fecal odor burrowed beyond the limits of the growth, under the right labium majus, the nates, and the vagina. After two months, the patient was discharged cured. Dr. von Biernacki has found records of four other cases of post-rectal dermoid cyst.—*Brit. Med. Journal*, October 1, 1887.

Note Upon the Local Use of Fluid Extract of Quebracho.

Mr. Bourdeaux writes to the *Archives Méd. Belges* that, according to his investigations which have been conducted within the last few years, quebracho is an energetic aid to cicatrization. Painted upon fresh wounds with a smooth edge, it produces transient stimulation and slight pain, just like collodion, and secures healing by first intention. It can also be used with good results in burns and frost bite, if the ulcerated spots have a good ruddy aspect. The fluid extract of quebracho hardens in an hour after being painted on, and forms a brown crust resembling dried blood, which clings firmly to the tissue and can only be removed by warm water. The secretions of the wound dry up,

and if the crust falls off the wound has healed, so that here healing under a scab can be properly spoken of. One great advantage of this treatment consists in the fact that all bandages may be dispensed with.—*Deutsche Medizinal-Zeitung*, September 22, 1887.

The Antiseptic Value of Roasted Coffee.

Dr. L. Keim writes to the *Münch. med. Wochenschr.*, in recommendation of coffee as an antiseptic, declaring that it not only retards fermentation, but also disinfects by killing the fungi. This power is found not to exist in even a strong solution of caffeine, but rather in an ethereal solution of the empyreumatic oil of the coffee, although the experimental proof of this has not yet been adduced. As we already have better antiseptics, infusion of coffee can only be employed when one needs to improvise an antiseptic for use as a prophylactic. For this purpose the powdered coffee is probably more active than the infusion, and the question arises whether the same action can be expected from the former as from the latter. Nevertheless, freshly ground roasted coffee applied to fresh wounds both prevents the development of spores within the wound and offers a useful antiseptic protective against impurities from without.—*Deutsche Medizinal-Zeitung*, September 22, 1887.

Very Rare Presentation in Midwifery.

W. H. Borham reports the following rare case, which he says he never saw before during forty years' experience:

Upon examination of the patient, he found the cord hanging external to the vulva in a loop about three inches long; there was a slight pulsation in it, and it was getting cold. Upon introducing his fingers, he found that the palm of the child's left hand was flat and pronated on the side of the child's occiput, between it and the mother's sacrum. In the interim of the pains, which were flagging, he at once introduced his hand into the vagina, pushed up the child's hand and head, then, by gradually insinuating his right hand into the uterus, grasped the left foot, turned the child, and in a few minutes delivered the mother of a female child. It had suspended respiration, but the heart was still pulsating. With the usual treatment of warm bath, etc., the child was restored, and both are now quite well.—*Lancet*, Oct. 15, 1887.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D., } EDITORS.
CHARLES W. DULLES, M. D., }

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	- 2.50
Reporter and Compendium,	- 6.00
Physician's Daily Pocket Record,	- 1.50
Reporter and Pocket Record,	- 6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

CORROSIVE SUBLIMATE AS AN ANTISEPTIC.

There is a valuable paper by DR. ERNEST LAPLACE, of New Orleans, in the columns of the *Deutsche med. Wochenschrift*, of October 6, 1887. In this paper Dr. Laplace describes the results of an admirable series of experiments made in Koch's laboratory, in Berlin, with corrosive sublimate as an antiseptic. The conclusion at which Dr. Laplace arrives is that the action of corrosive sublimate as an antiseptic is materially enhanced by combining it with tartaric acid. For this purpose he recommends the use of two solutions, one for washing wounds, and the other for impregnating surgical dressings. The first solution is composed of: corrosive sublimate, one part; tartaric acid, five parts; and distilled water, a thousand parts. The second solution is composed of: corrosive sublimate, five parts; tartaric

acid, twenty parts; and distilled water, a thousand parts.

The evidence which Dr. Laplace presents to show that these solutions are effective as antiseptics is conclusive, and they have also the merit of cheapness. They do not destroy the fabric of which surgical dressings are made, and they can be used in conjunction with iodoform.

In the same paper, the author speaks briefly of the effect of adding hydrochloric acid to corrosive sublimate for disinfecting purposes. Our readers are, no doubt, aware that this combination is more efficient than either substance is alone. But it will be interesting to note that Dr. Laplace finds that a mixture containing one part in twenty thousand of corrosive sublimate, and one part in ten thousand of muriatic acid, will destroy the spores of anthrax in twenty-four hours. It would be interesting in this connection to know how much the addition of common salt to a sublimate solution would affect its antiseptic power. Perhaps some of our readers will follow this subject up.

THE VITALITY AND CAPABILITIES OF BLOOD-CELLS.

As the result of five years of patient study, A. P. FOKKER (see *Centralblatt f. d. med. Wissenschaften*, October 1, 1887) announces some remarkable discoveries in regard to the vitality of blood-corpuscles, which have a most important bearing upon a number of problems in medicine, and even in philosophy. Fokker took blood, under the strictest conditions of asepsis, from the carotid artery of rabbits, and brought it into sterilized vessels containing fluid culture mediums prepared with equal precautions. He found, as a rule, that no bacilli were developed, and that the blood continued *to live*, and gave rise to the production of a determinable amount of acid. He came to the conclusion, further, that animal protoplasm has the property—without the co-operation of bacteria—of causing decomposition, and that they retain this power for months in the presence of a proper nutritive material. The difference between or-

ganized and unorganized ferments consists in the fact that the latter have no power of multiplication. Portions of organs, which are not themselves decomposed, continue to live, and the decomposition to which they give rise is a manifestation of life.

Another part of Fokker's investigation dealt with hæmatocytes, certain living bodies which can be produced from blood by cultivation. When he studied blood—again with the strictest aseptic precautions—in the presence of nutritive material, containing sodium, calcium and sulphates, he found that hæmatocytes were developed in from two to three weeks at a temperature of 38° – 40° (centigrade), and in a prepared complex medium, at a temperature of 50° – 52° , so rapidly that their development could be seen on a warmed object glass. He regards hæmatocytes as living bodies; and he found that blood-cultures, which had been kept for a whole year, could be made to produce new crops of hæmatocytes in the presence of new nutritive material. Certain of his investigations led him also to the conclusion that bacteria could develop out of hæmatocytes.

The important bearing of these studies upon various vital processes, including those of the generation of bacteria, can hardly be estimated. It staggers the imagination to conceive the possibilities suggested by the thought that blood-cells may retain their life and their vital functions long after the death of the individual from whom they have been taken; and if it be true that they may actually produce bacteria, without previous infection, the science of bacteriology may have to be reconstructed.

CHEMISTRY VS. BACTERIOLOGY.

In the present state of bacteriology, it is interesting to find contributions to its proper appreciation which indicate that the part played by bacteria alone is not to be overrated. Many careful thinkers have believed, without being able to prove it, that much of the results sometimes attributed to bacteria ought rightly to be attributed to the chemical

substances which they produce, or which accompany them. In the *Archiv für pathologische Anatomie*, October 3, 1887, Prof. P. GRAWITZ, of Greifswald, describes the results of a series of experiments with cadaverin, an alkaloid belonging to the group of ptomaines, which indicate that this substance is capable of exciting suppuration without the presence of the "specific" micrococci of pus. So far is it from requiring the assistance of these cocci, that it is actually capable of destroying them, when they are present. This destructive power is exerted even when the alkaloid is tested in a $2\frac{1}{2}$ per cent. dilution.

But, while cadaverin seems to be able to destroy the peculiar coccus of pus, it favors the development of a large bacillus. Grawitz found, however, that this bacillus does not give rise to suppuration when injected into living animals.

The results of these investigations harmonize with those of others, which tend to show that it is not wise to attribute to bacteria every process with which they are associated. A very refined chemistry must be called to the assistance of bacteriology before we can hope to arrive at a correct understanding of the phenomena of disease. Our forefathers were of the belief that the chemical products of decomposition could cause surgical diseases, and their views are corroborated by such facts as Grawitz adduces, notwithstanding the fact, which seems to be well established, that these diseases are often propagated by specific bacteria.

A careful review of what has already been done in investigation of the part which chemical substances play in the production of morbid processes, indicates that such investigations present a fruitful as well as fascinating field for future study, and one which may well engage the attention of American students of pathology.

RESEARCHES ON MENSTRUATION IN SYRIA.

The *Centralblatt f. d. med. Wissenschaften*, October 1, 1887, cites an interesting paper of ROUVIER, from the *Annales de Gynécologie*, on the menstrual function in women

of various nationalities in Syria. These the author divides into fourteen groups, and finds that certain of them begin to menstruate at an earlier period than others. Temperature has no perceptible influence upon the period at which menstruation begins. Occupation, on the contrary, does influence it; for Rouvier finds that women who work do not begin to menstruate so soon as those who live at ease. The length of the menstrual period is greater in hot countries than in temperate or cold regions, and in both the menstrual period in working women is shorter than that in women of ease. As to the menopause, Rouvier finds that it usually occurs at the age of 45 years; and that the period of its occurrence is not affected by the age at which menstruation begins.

HYPODERMIC MEDICATION OF ANIMALS.

Many of our readers who live in the country, and probably some who live in the city, are interested in the treatment of domestic animals. To these it will be of value to learn that ELLENBERGER reports (see *Centralblatt f. d. med. Wissenschaften*, October 1, 1887) the results of a thorough study of the effect of the hypodermic administration of 31 remedies to horses, sheep, dogs and rabbits. He finds that pilocarpine and muscarine are very valuable cathartics, when administered hypodermically. For many cases he finds a combination of pilocarpine or muscarine, with physostigmine, desirable, because the former produces increased secretion from the intestinal glands and mucous membrane, while the latter produces increased peristalsis.

CHEERFULNESS.

One of the greatest opportunities of the medical man is that he often has it in his power to brighten the sick-room, and to allay the anxieties of a patient, and of those who love him, by a cheerful demeanor. This fact is not unknown to, or unappreciated by, most physicians; and it is not to discuss the value of a well directed cheerful disposition

that we bring the subject before our readers. On the contrary, it is in order to say a word about a mistake which may be made by being too cheerful.

There are times when gravity is more in place than the best meant cheerfulness. Such times are when an illness assumes a serious aspect, of which it may be the right of the patient, or of some one of his attendants, to be informed. It sometimes happens that a man, or a woman, is very ill indeed; that the physician feels it to be important that no depression of spirits should be added to that of the body; and, yet, it is desirable that some responsible person should be informed of the danger which threatens. At such a time, it is not right to keep up assurances of safety, or even of much hopefulness, so as to deceive those who have the greatest interest in knowing the truth. This would be pushing cheerfulness too far, and might lead to a calamity. In such a case cheerfulness would be a fault—even though a generous fault; and those who suffered by it would hardly forgive the physician, no matter how good his intentions might have been.

THE CROWN PRINCE'S THROAT.

Recent despatches from Germany seem to confirm the opinions which were expressed in the REPORTER of June 4, in regard to the nature and probable issue of the growth in the throat of the Crown Prince of Germany. In spite of the hopeful bulletins which were telegraphed from Europe, the progress of the case has been such as to give great concern to those who have had clinical experience with malignant growths. And now, it is reported that the state of the Crown Prince's throat is so serious that a grave operation—probably extirpation of the larynx—has been decided upon, and Professor von Bergmann has been selected to perform it.

The present aspect of this case is not only very sad in its personal bearings, but also very serious in its bearings upon the welfare of the German Empire.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

OPERATIVE SURGERY ON THE CADAVER.

By JASPER JEWETT GARMAN, A.M., M.D., F.R.C.S., etc. 8vo, pp. ix, 150. New York: D. Appleton & Company, 1887. Price, \$2.00. From P. Blakiston, Son & Company, Philadelphia.

This book contains a simple and clear statement of the way in which a large number of operations are to be performed upon the cadaver, and can be recommended to the use of teachers and students in this important part of a surgical education. We hardly agree with the sweeping statement that "to introduce rubber catheters (into the bladder) requires no manipulative skill;" although it does not require much in most cases.

We observe that the author, in speaking of the use of the hypodermic syringe, does not refer to injections into the substance of muscles; which are usually easier to make, and often more desirable than those under the skin. We would suggest also that an imitation of the operation of herniotomy might be introduced with advantage into such a book as this; and in the matter of suturing tendons, a description of the suture proposed by Kocher (Arch. f. klin. Chirurgie, Bd. xxxiv, 1886). Other points arise in our mind—as, no doubt, they have arisen in that of the author since he saw his book in print—but it would be hypercritical to mention them. The book is an excellent one, and calculated, we believe, to be very useful in the sphere for which it was intended.

UEBER DEN MECHANISMUS DER SCHÄDELBRÜCHE (ON THE MECHANISM OF FRACTURES OF THE SKULL). INAUGURAL DISSERTATION. By WILHELM GREIFFENHAGEN. 8vo, pp. 79 (paper), with 5 plates. Dorpat: Schnakenburg's Buchdruckerei, 1887.

This work is one of a kind not uncommon in Europe, in which a graduating thesis bears the marks, not only of the diligence of the student, but also of the wise guidance and assistance of the preceptor. In Europe, very many valuable studies of special subjects have been prepared in this way—the preceptor furnishing the suggestion of a subject and of the way to treat it advantageously, and the student doing all the rest of the work. In the present instance, we have an admirable presentation of what is known as the "bursting-theory" of indirect fractures of the skull—a theory which has been ably defended by Messer, Greder and others in Germany, and by Von Wahl in Russia, and advocated at some length by one writer in this country. It seems to us so reasonable, that we wish the subject might receive more attention from English and American surgeons than it has yet had.

TREATISE ON HUMAN PHYSIOLOGY.

For the use of Students and Practitioners of Medicine. By HENRY CHAPMAN, M.D., Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia, etc. 8vo, pp. xvi, 945. Philadelphia: Lea Brothers & Company, 1887. Price, cloth, \$5.50; leather, \$6.50.

Dr. Chapman is peculiarly well fitted for the preparation of a treatise on human physiology by his extensive acquaintance with the whole range of zoölogical science; and everywhere in his book the

evidences of this acquaintance, and of its value in discussing the subject in hand, are apparent. The author's style is pleasant, so that this book is not only instructive, but also interesting. Our space does not admit of a critical review of his teachings; but they may be said to be generally abreast of the present knowledge of physiology. There appear to be some omissions—for example, we have searched in vain for any mention of the blood plaques of Bizzozero, or haematocytes, in the chapter on the blood; and we cannot find any discussion of the problems of intracranial pressure from the blood and cerebro-spinal fluid, or of the effects upon pulse and respiration of pathological or experimental alteration of this condition. We incline, also, to the opinion that more space is devoted to the study of electricity than is necessary in a work of this sort.

THE PRINCIPLES OF THEORETICAL CHEMISTRY, WITH SPECIAL REFERENCE TO THE CONSTITUTION OF CHEMICAL COMPOUNDS. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Third edition, enlarged and thoroughly revised. 8vo, pp. xii, 318. Philadelphia: Lea Brothers & Company, 1887. Price, \$2.00.

This work, by a recognized authority, has already met with so much favor at the hands of those best qualified to appreciate its merits, that there is little for us to do, in noting the appearance of this third edition, but to congratulate its author upon its success, and wish for a continuance of this success.

TO WHAT EXTENT CAN WE CLASSIFY VESICAL CALCULI FOR OPERATION?

By A. VANDEVEER, M.D., of Albany, N. Y. 8vo, pp. 48 (paper). Reprinted from the Transactions of the American Surgical Association, 1887.

This pamphlet contains the opinions of the author, founded upon an experience of forty-one operations for stone, the histories of which he gives. He does not answer the question in the title very satisfactorily; but seems to think litholapaxy the best operation for stone in general, and to have a favorable opinion of the suprapubic method of lithotomy.

—The Faculty of Medicine of Paris has escaped much public obloquy. Pranzini, a vulgar criminal, who murdered three women for the sake of robbery, was duly executed some time ago, his body being sent for dissection to the laboratory of the Faculty. Ugly rumors soon gained currency that a professor *agrégé* had caused Pranzini's skin to be tanned and made into card-cases. But an investigation has shown that some of the skin had been surreptitiously taken by a laboratory porter and given to a member of the police force, who really had the card-cases made and presented to two of his superiors. So it turns out that the Faculty was not guilty of impropriety. The three implicated police officials, Messrs. Taylor, Goron and Rossignol, find themselves in an awkward predicament, expecting to be dismissed. Some wits say that, living, Pranzini killed three women, and is going to cost three men their heads after losing his own.

CORRESPONDENCE.

Ophthalmia Neonatorum.

EDS. MED. AND SURG. REPORTER,

Sirs:—In the treatment of ophthalmia neonatorum, every hour, day and night, the lids are gently opened, and the discharge washed out with tepid water, and removed with a soft, moistened rag; or a syringe may be used. Every six or eight hours a few drops of a solution of alum, grs. ij-iv, in an ounce of water, are to be dropped into the eyes after the washing. Occasionally, after a week's treatment or thereabouts, a case will remain stationary; and then a solution of nitrate of silver, grs. ij in an ounce of water, may be substituted for the alum drops with satisfactory results. The main point is the repeated washings to remove the discharge.

The above is an old-fashioned treatment, and during an experience of thirty-two years it has proved so satisfactory that the writer has never had any desire for a change.

BACKWOODS.

London, Ontario, Nov. 1st, 1887.

EDS. MED. AND SURG. REPORTER,

Sirs:—Under the head of "Notes and Queries," I would like to ask, as an old subscriber of the MED. AND SURG. REPORTER, your own views and those of any of your subscribers, as to the galvano-cautery treatment in hay-fever. I have myself had no experience in this method of treatment; but as I have one or two patients who suffer severely every fall from this troublesome disease, would be pleased to have the views of some of the more experienced in the medical profession, in regard to it. Would I be justified in recommending them to incur the expense of a trip to some of the Eastern cities, with a view to undergoing that treatment?

Please reply, and oblige one of your old subscribers.

J. R. WALKER, M.D.

Regersville, Tenn., Oct. 27, 1887.

[We have serious doubts of the general applicability of cauterization in the treatment of hay-fever. But we think that the patient referred to above would do well to consult a skilful specialist in diseases of the nares, and follow his advice.—EDS. REPORTER.]

NOTES AND COMMENTS.

The Proper Splint for Gunshot Fracture of the Lower Limbs in Connection with Transportation.

R. F. Tobin, F.R.C.S.I., in a paper on this subject in the *Lancet*, October 15, 1887, after stating that his remarks will apply to gunshot fractures of the hip and upper third of the thigh, says that an appliance, which will give rest to a fracture in the locality indicated, must fix not only the injured limb, but also its fellow, and the trunk as far as the thorax. Liston's and Bryant's splints are satisfactory when the patient is on his bed; but no splint, as far as known, on which the limb does not rest by its own weight, gives satisfactory support when for any purpose the patient has to be lifted. The foregoing conditions are fulfilled by the splints of Thomas, of Liverpool, and Fagan, of Belfast. The objection to using these on the field is due in the former splint to the difficulty in fitting it, and in the latter to its costliness. It is hoped that these obstacles, which are not insurmountable, will be overcome. In the meantime, the author purposes the following dressing, which he says can be rapidly applied, and forms the most available dressing for gunshot fracture of the lower limbs in connection with transportation.

Having treated and dressed the wound after the fashion in vogue for wounds in general, the canvas of a stretcher with removable poles is spread upon the ground, and is cut transversely into two about its centre. The following materials are also made ready: (1) Two pairs of trousers, viz., that of the wounded man and any other obtainable of about the same size; (2) a few strips of blanketing, or a few large towels or other material, of a size to go as a binder round the waist and hips in three or four layers; (3) one stone and a half of plaster-of-paris; (4) three gallons of water; (5) a bucket or other receptacle in which to mix the plaster and water; (6) three yards of calico torn into three many-tailed bandages; and (7) a roll of cotton wadding. The plaster is mixed with about an equal quantity by measure of water, and into the creamy fluid so formed, the two pairs of trousers and the material that is to go round the waist and hips as a binder, are immersed. When these have been thoroughly imbued with the fluid, the trousers are spread out one over the other on the canvas of the stretcher, the forks of the combined trousers being made to lie a few inches away from and above the

division in the canvas, and a many-tailed bandage placed, ready to be tied, under each leg. The material which is to form the abdominal binder is spread, with a many-tailed bandage underlying it, transversely under the waist of the trousers; and over all a thick layer of wadding is layed. On to the splint thus formed the patient is lowered in such a position that the margin of the fork of the trousers corresponds to a point two inches and a half above the arms, and that his legs, being immediately over each leg of the trousers, are about six inches apart at the knees. The fractured limb is held in good position by the surgeon, while two assistants, by tying together the tails of the bandage, bring the splint into close apposition with the posterior surface of the patient's legs, buttocks, and loins, and make the binder encircle the hips and abdomen. As soon as the plaster has set, the poles are passed through the folds in the canvas and the patient is removed. The whole dressing, not including the treatment of the wound and the setting of the plaster, can be applied in less than a quarter of an hour by a surgeon and two skilled orderlies. During the subsequent treatment of the case the canvas of the stretcher is never removed from underneath the patient. When an action of his bowels is about to occur, the poles are put in position, the halves of the canvas are separated, the patient is raised, and the bed-pan passed underneath him. He is lifted in a similar way when his wound requires to be dressed. The situation of this may require that windows be made in the splint and canvas; and in cases where it is apparent that this will have to be done, hoop-iron, if obtainable, should be placed between the trousers, when first put in position, so as to strengthen the splint under the injured limb.

Jhambul in Diabetes.

In the *Maryland Medical Journal*, October, 29, 1887, Dr. W. H. Morse gives an account of jhambul, from which the following abstract is taken: The drug is obtained from the bark, but especially the seeds, of a small evergreen shrub, whose habitat is the humid regions of India. It is administered in the form of a powder, the dose of which is five grains three times a day.

According to Dr. Morse, the action of the drug, in the dose mentioned, is threefold. (1.) The excretion of urine is lessened in quantity. (2.) The specific gravity is lowered at once. (3.) The formation of sugar in the urine is arrested by a prevention of

the conversion of starch. Among other minor actions may be enumerated a checking and control of the boulimia and abnormal thirst, an improvement in nutrition, and a permissible removal of the restrictions of diet. During treatment the patients are excitable, but sleep well, and gain strength rapidly.

In a word, uniformly successful results are obtained speedily and without compensation. Exceptions are noted in fat subjects, and where phthisis complicates. Although these classes of cases are decidedly ameliorated, it cannot be said that any have been cured. In all other classes a cure is the rule, the arrest of the changes in the nervous system which accompany or cause the disease being an early accomplished fact. Health is regained even when the disease is of long duration, and when the patient is in an apparently hopeless condition.

In enteritis, acute gastritis, and peritonitis, the results attending the use of jhambul are very gratifying, and the author only regrets that a limited experience prohibits the giving of a line of testimony of particular interest. To increase the action of the heart the indications from the use of jhambul are promising.

As the author begins his consideration of the therapeutics of jhambul by saying: "It is as yet too early to enter far on the therapeutical actions of jhambul," his positive statements as to its curative powers in diabetes seem unwarranted. It is not clear either, from the paper, by what process the author arrived at the conclusion that "the formation of sugar in the urine is arrested by a prevention of the conversion of starch."

The Lime Treatment of Cancer.

Dr. P. Hood, in a letter to the *Lancet*, October 1, 1887, refers to a former communication by him in which he recommended the carbonate of lime obtained from oyster shells as a cure for cancer. He says that the pharmacopœia preparation may be used in doses of six grains in a wineglassful of milk or other fluid, such as tea, two or three times a day. He also recommends the following ointment as a local application:

R Cretæ preparatæ.....ʒiij
Ol. amygdal fʒij

Mix the lime intimately with the oil and add two ounces of lanoline. Apply twice a day.

Should the smell be unpleasant, three or four drops of oil of bergamot or geranium will correct it.

Transient Œdema of Half the Lip.

Dr. Alfred W. Hughes reports the following interesting case to the *Brit. Med. Journ.*, September 24, 1887: A case to which I have given the above designation came under my notice a few days ago, when I was called to see a patient whose lower lip had become enormously swollen during the night, the swelling being confined to one side, extending only to the middle line of the lip, where the line of demarcation between the swollen and healthy tissues was very definite. The patient told me that some years ago a similar swelling occurred, which also appeared during the night, and, like the present one, disappeared gradually during the early part of the following day, having caused no inconvenience beyond a slight difficulty in articulation and mastication, which was not due to any pain, but simply to the large size of the lip. I may mention that a lymphatic gland, which I considered abnormally large, could be felt on the same side of the face, on the surface of the jaw near the anterior margin of the masseter muscle, but this the patient informed me was always of the same size.

I recommended no treatment, for, as I anticipated, the swelling disappeared in the course of a few hours, but I was naturally expected to explain the condition. At first, upon noticing what I considered an enlarged gland in the course of the lymph stream from the part, I thought the swelling was due to lymphangiectasis, from some blocking of the lymph vessels, or some interference with the flow of lymph through the gland; but were it of this nature, it would have been preceded by an inflammatory condition of the lymphatics or lymphangitis, with the ordinary symptoms of inflammation—namely, heat, redness and pain, and a dilated condition of the lymphatic vessels—would have been apparent beneath the skin and mucous membrane of the lip, which symptoms and appearances were here entirely absent. I therefore consider the following a more feasible explanation, that during sleep the facial vein was compressed at the point where it crosses the lower jaw, thus stopping the flow of blood through it. This compression would not interfere greatly with the venous circulation in the upper part of the face, due to the communication which exists between the facial vein and the pterygoid plexus of veins beneath the masseter, which veins open into the internal maxillary vein, a radicle of the external jugular. But the flow of blood out of the veins of the lower lip would be greatly impeded, as these veins open into the

facial below the communication above mentioned, which communication is therefore unable to relieve the inferior labial veins which are now engorged.

This engorgement would lead to extravasation of lymph and swelling, unaccompanied by any inflammatory symptoms; and this swelling is transitory, because, when the compression is removed, the circulation returns to its normal condition, and the extravasated lymph is reabsorbed.

Localized Sweating.

The *British Med. Jour.* of September 24, 1887, contains a letter from R. G. Wilde, who says: With reference to the cases of localized facial sweating, recorded in the *Journals* of July 9th and August 20th, the following may be of interest: M. H., a gentleman, when aged 22, suffered from supuration of the parotid, following typhus fever. The abscess was opened in three places, small scars now remaining—one just below the zygoma, one below the angle of the jaw, and the third in the anterior wall of the external auditory meatus. Profuse sweating now occurs on a patch about an inch in diameter, in the middle of the left cheek, invariably during mastication, or when any acid substance is taken into the mouth; never at any other time. There is not, and according to the patient's account never has been, any loss of power or sensation on that part of the face. This has now lasted for upwards of twenty years, coming on soon after the abscess had healed.

A second letter from W. J. Penny, F.R.C.S., says: During the last two months I have had two cases of localized sweating of the groin under my care, which may possibly throw some light on the cause of the cases of localized facial sweating published in recent numbers of the *Journal*.

In one of these cases the sweating appeared round the scar of a bubo. The bubo healed four or five years ago. After that the sweating came on, and has continued to the present time. It was very profuse and strictly localized, the other groin remaining dry. The patient consulted me on account of the discomfort he experienced from the perpetual damp condition of the part.

The second patient was recovering from a recent attack of gonorrhœa when he called my attention to a profuse sweating limited to his left groin. No signs of inflammatory swelling were apparent; but, on careful examination, the cord on that side was found slightly tender. The sweating in this case struck me

as possibly being a manifestation of a pre-inflammatory stage, and accordingly I treated him very carefully.

The first case had existed for some years, and was probably due to the altered condition of the parts—possibly to some change in the vaso-motor nerves of that region.

Pernicious Anemia and Bothriocephalus Latus.

In 1886, Prof. Runeberg suggested that pernicious anemia is sometimes due to the presence in the intestines of the tape-worm known by the name of *bothriocephalus latus*. Recently, Dr. Schapiro has recorded in the Russian journal *Vratch*, the history of a case which supports this view. The patient was a boy, 13 years old, with marked anemia, diminution of the proportion of red blood-corpuscles, tendency to hemorrhage, etc. After the administration of anthelmintics and the evacuation of a large quantity of segments of the *bothriocephalus*, he recovered.

Cases of Spontaneous Rupture of the Aorta and Heart.

In the *Lancet*, October 1, 1887, Mr. W. Goode Adams gives an account of a young woman, twenty-three years old, of healthy parentage and family history, who had been brought home on May 6, with the history that she had had cardiac pain, and had become faint. She was kept in bed for the next two days, and on the third was allowed to go out with her sister. After walking about twenty minutes, she was seized with violent pain over the region of the heart, and immediately became faint. She was at once taken home, but continued faint and semi-conscious until next morning, when she died. No physical signs of heart disease were detected during life. At the autopsy, the pericardium was distended with serum, and the heart invested by blood clot. A small opening, just sufficient to admit a probe, was found in the posterior wall of the aorta at its junction with the left ventricle, and almost touching the point of attachment of the semi-lunar valves. There was also a transverse rupture of the inner coat of the aorta, extending nearly entirely around the aorta, and a little higher up than the point of rupture of the external coat. No areas of fatty degeneration were found. The kidneys were full of cysts. This case is supposed by Mr. Adams to be a remote sequel of typhoid fever, from which the patient had suffered eleven months before, but he thinks the immediate sequel was the kidney disease. The rupture of

the walls of the aorta probably occurred on two separate occasions, at an interval of four days, during which interval a dissecting aneurism began to form.

Mr. Adams also reports the case of a patient fifty-nine years old, who had suffered for some months with occasional but slight pain in the cardiac region, the pain radiating into the arms. On the morning of his death, while in the water-closet, he was heard to vomit, and on coming out said that he felt faint and would go up and lie down on his bed. An hour afterwards he was found there dead.

At the autopsy, a very small valvular opening was found in the anterior wall of the left ventricle, running upwards and inwards. The opening would only admit a small probe. The heart muscle was in a state of fatty degeneration, while the aortic valves were atheromatous, and so, likewise, were the coronary arteries.

These two cases are interesting, particularly the first one, on account of the supposed mechanism of the rupture and its remote cause. Neither of them, however, compare with the extraordinary case communicated to the *REPORTER* (Oct. 8, 1887, page 479) by Dr. John C. Holmes.

Imaginary Ulcers of the Tongue.

At a meeting of the French Academy of Medicine, on September 27, 1887, M. Verneuil spoke of imaginary ulcers of the tongue which, he said, were characterized by pain and by the taking of the natural condition of the part for an ulcer. The persons affected are, in Verneuil's experience, men from thirty-five to fifty years of age and of the best bodily condition, though giving evidence of gout. Tobacco did not seem to have a serious influence. The course of the disease is irregular, and the pain of variable intensity, but the disease is chronic and rebellious to treatment. One of the five patients, whom the author has seen, died, three years after the first visit, of general paralysis; the others recovered. The prognosis is doubtful, because of the persistency of the pain. Verneuil recommends alkalies, arsenic, the bromides and local anodynes. He would also like to suggest the use of parenchymatous injections of morphine into the tongue, and the application of the cautery to the painful points.

M. Fournier expressed the opinion that the disease is not as rare as M. Verneuil seems to think, and regarded tobacco as one of the causes.—*Progrès Médical*.

Alarming Syncope from Syringing the Ear.

In the *Lancet*, October 15, 1887, Mr. J. Middlemass Hunt, M.B., Surgeon to the Throat and Ear department of the Newsham Dispensary, Liverpool, reports that he was called to see a boy with suppurative disease of the right middle ear, who had suddenly fainted after his ear had been syringed out by his mother. It should be stated that previous to the syncope the child had been running about apparently well. He found the boy in profound coma, with slow, irregular respiration, rapid pulse, lividity of the lips, cold extremities, and dilated pupils. He considered the boy to be at the point of death, but ordered mustard to be applied to the nape of the neck and the lips moistened with brandy and water. In a few minutes after the mustard was applied the child became conscious and to all appearances as well as usual, except that he was somewhat pale and languid. There were no signs of caries in the ear, and the urine was free from albumin. The child has since remained well.

Roosa has reported a similar case, which occurred in a man forty-five years of age, but gives no explanation of the cause of the coma. Hunt is disposed to think that it is a nervous reflex starting from the termination of the auditory nerve in the semicircular canals and labyrinth, or from the tympanic plexus. Lockhart Clarke has demonstrated a connection between the roots of the fifth cerebral, the glosso-pharyngeal and the vagus.

A. New Method of Treating the Vomiting of Pregnancy.

In the *Lancet*, October 15, 1887, Dr. William Duncan, F.R.C.S., assistant Obstetric Physician to the Middlesex Hospital, reports three striking cases of the vomiting of pregnancy, in which he obtained complete and rapid relief by the local application of cocaine to the vagina and neck of the uterus. The first patient was a woman of nineteen years, who had persistent vomiting for a month. She was two months pregnant with her first child. The uterus was markedly ante flexed and tender on pressure. The roof of the vagina and the cervix were painted freely with a 15 per cent. solution of cocaine, and a plug of cotton-wool soaked in this solution was carefully inserted to a depth of three-quarters of an inch into the cervical canal. The patient returned in a week reporting that she had not vomited once in the interval.

The second case occurred in a woman

twenty-six years old, three months pregnant with her second child. The uterus was normal in position, but tender on pressure. The same treatment was followed by a precisely similar result.

In the third case, a woman twenty-three years old, pregnant two months and a half, had been vomiting for six weeks. The uterus was somewhat ante flexed. The same treatment was used, except that the cocaine was not applied to the cervical canal. In a week the patient returned saying that she had not vomited for the first four days, but since that time it had recurred. The vagina, and this time the cervical canal also, was again painted, and vomiting had not recurred when the patient again reported in a week.

In conclusion, the author speaks guardedly of the ultimate value which may be put upon this method of treatment, and calls attention to the danger of exciting abortion from a careless application to the cervical canal.

How to Keep Ice From Melting.

It is often a most important matter to be able to preserve ice from melting quickly in the sick-room. Various devices have been suggested for this purpose; but the most efficient seems to be one proposed by Dr. Julius Stumpf, in the *Allg. Med. Central-Zeitung*, Sept. 14, 1887. Dr. Stumpf recommends the use of chaff—barley-chaff. He says that a piece of ice placed in a bag, and then in a box or basket containing enough barley-chaff to surround it with a layer five or six inches thick, will not lose 25 per cent. of its weight in five or six days, in a room, the temperature of which is between 70° and 80°. This suggests an excellent way to preserve various articles of food and drink, as well as ice itself.

Elixir of Cascara Sagrada.

A committee appointed by the British Pharmaceutical Conference, held in 1886, to prepare a formulary of unofficial remedies, reported the following formula for cascara sagrada:

℞ Tincture of fresh orange peel... 2 fl. ozs.
Rectified spirit..... 1 fl. oz.
Cinnamon water..... 3 fl. ozs.
Syrup..... 6 fl. ozs.
Fluid extract of cascara sagrada... 8 fl. ozs.
Mix.

Dose: 15 minims to 2 fluid drachms.

—*Druggists' Circular.*

NEWS AND MISCELLANY.

Coffee and Tea.

"The berry of Mocha" is declining in public favor, according to the latest returns of the Commissioners of Customs. To many persons this will not in the least be a matter of surprise, for it will in all probability only confirm that which they had noticed to be the case during the last few years. Coffee unquestionably has its drawbacks as a beverage. To glean from it its full flavor, the berries must be freshly ground, and, generally, care exercised in preparing it, otherwise anything drinkable is better than coffee. Those tourists who have paid a visit to Norway will doubtless have a lively recollection of the superlative character of the flavor of the coffee which is provided in the Norwegian hotels, and the explanation of this fact is readily forthcoming to any one taking the trouble to inquire. The berries are taken in their green state and freshly roasted, and there is generally only one person in the establishment who understands the process; the goodness of the infusion altogether depends upon the degree of roasting, a fact which the Norwegians thoroughly admit. Perhaps coffee is most out of place when it is drunk after a full meal. Nothing can be conceived more harmful for digestion than coffee, as handed round at dinner parties. The mixture of wines on these occasions is far from a consummation devoutly to be wished, but mixed wines diluted with a concoction of coffee is too appalling for anything. Let any interested person make the experiment, not upon himself, but in a glass receptacle, and then let him view the mixture, and ask himself whether it looks inviting enough to imbibe. Much of the discomfort which is felt in the morning after "dinners" may be attributed to the postprandial cup of coffee which has been indulged in, and which should have been avoided. This is a little matter, which, we may rely upon it, the stomach has found out, and which it accordingly resents. However, in its place, in the long run coffee is less harmful than tea. The flatulent dyspepsia, which from the depression of spirits that is caused, has probably not a little to do with the cases of women who largely follow the practice of "pouring spirits down in order to bring the spirits up," is one of the most common results of indiscriminate tea-drinking. There is, it must be confessed, a sequence of events in these instances. First, the tea-imbibing to excess ;

secondly, the flatulent dyspepsia with depression of spirits; thirdly, the resort to alcohol to correct the depression, with consequences which exhibit a remarkable variety. The principle of cause and effect is, of course, in these cases lost sight of. Probably many a woman, at first against her will, is led on by this means to become a confirmed tippler, not because the human predilection for alcohol induces her to give way, but because she is over-burdened with something of which all mankind has the intensest hatred, "the blues," and for this she finds gin and whisky unfailing remedies. But the poor are partial to tea, and one of their reasons is, that it enables them to get along with less nourishment, and by this means helps them to economise in their food. We do not dispute the reasoning; it may be possible that theine diminishes tissue waste; we should, however, be much more inclined to believe that the inimical effect of tea-drinking upon the gastric mucous membrane banished the appetite, and rendered eating almost impossible, not from choice, but from compulsion. "The Prince of Tea-drinkers was Dr. Johnson, one of the most sedentary of men, and the most unhealthy." But it is scarcely to be believed that all his tea-drinking could have done him any good; on the contrary, a martyr, so to speak, to struma as he was, he probably aggravated his constitutional malady by the habit.—*The Med. Press and Circular*, Sept. 14, 1887.

Leprosy.

Dr. Besnier stated in the course of a paper on leprosy, which he read at a recent meeting of the French Academy of Medicine, that there are always a few cases of leprosy under treatment at the Hospital of St. Louis, in France, and that the number tends to increase with the spread of the French colonial empire. Leprosy is now known to be a microbial disease. The bacillus is scarcely distinguishable in appearance from the bacillus of tuberculosis. It was at one time believed that particular climatic conditions and particular articles of food—notably certain species of fish—were capable of producing the disease; but this theory is now abandoned. Leprosy, Dr. Besnier affirms, is propagated by contagion, and by contagion alone. The bacillus is not found in the soil or in the water of the regions where the malady prevails. It is, therefore, by its direct passage from one human organism to another that the disease which it causes is communicated and spread.

Killing a Monstrosity.

A Calcutta despatch to the London *Times* says: An extraordinary appeal case has lately been heard in Madras which shows the character of existing superstitions. It seems that one of the accused in the original case gave birth in December last to a male child having four eyes, the face of a monkey, and crooked arms and legs, while it grunted like a pig immediately on its birth. The midwife placed the child under a trough and sat upon it, both she and the mother raising cries of alarm. The male prisoners then came and took the child into a field and killed it by striking it on the head with a club. Their explanation was that the child was an evil spirit, which they were justified by the custom of the country in killing in order to prevent it from doing evil. The judge acquitted them on the ground of a mistake of fact. This decision was necessarily upset on appeal. The accused believed that unless the child had been killed it would have grown to an immense size and devastated the country, and that they were therefore committing a meritorious action in obviating so grave a public calamity.

Preserving Oysters in the Shell.

Mr. M. A. Freeman, of Philadelphia, has recently patented a method of preserving oysters in the shell, which promises to revolutionize the business of shipping them, and to make it possible for oysters to be obtained in the best condition at the greatest distance from the sea. According to the *Public Ledger*, October 28, the invention consists simply in so fastening the two shells of a living oyster together that they cannot open. The inventor claims that death and subsequent decomposition of an oyster are due to the introduction of air, that in the normal condition the shell is completely filled with the body of the oyster and his liquor, and that the two shells close together so perfectly that if they are not allowed to open not a drop of liquor can leak out nor a bubble of atmospheric air leak in.

The plan is wholly original, but the inventor states that it has been thoroughly tested. In 1884 he shipped oysters to Denver, Colorado, fastened together with Yankee clothes-pins, and they carried safely. After some experiment he adopted iron wire, and has some remarkable records of the results. On the 17th of November, 1886, a barrel of clamped oysters was shipped to a Liverpool firm. The last of the oysters were sampled on the 7th of February, and were in salable

condition. Another barrel made a round trip over the Atlantic on the steamship Lord Gough, occupying thirty-seven days, and were eaten by gentlemen interested, at the end of the voyage, and were pronounced excellent. Others have been shipped to San Francisco and the extreme Northwest.

Activity of Surgeons.

The recent death of the famous surgeon, Professor Langenbeck, has called attention to the fact that great surgeons not only as a rule are blessed with long life, but are very unwilling to retire from their profession till compelled by old age, although to the lay mind surgery does not appear a specially enjoyable employment. Dr. Spencer Wells relates that when Dr. Astley Cooper became too infirm to practice on human patients any longer, he continued to treat cows, horses and dogs; and one day, when a visitor called on him, Cooper asked: "Do you know what is my favorite employment at present?" "Well?" "To go about my garden and select the tree best adapted for hanging myself." One obvious reason why surgeons live so long is that they know how to take care of their health. Thus Dr. Billroth, of Vienna, during a recent sojourn in the country, never neglected his daily heart and lung gymnastics.

A Serious Mistake.

A very serious mistake occurred in a Vienna pharmacy recently, attended with extraordinary circumstances. Two girls entered at the same time and were waited upon simultaneously by two different assistants. They both brought bottles of about the same size, in which one wanted oil of vitriol (dil.), and the other "Kindermeth" (presumably syrup of rhubarb comp.) The assistants were confused by the similarity in the appearance of the girls, and gave the acid to the one wanting the "baby syrup." Despite the fact that the latter is a familiar preparation, and of a brown color, the acid was administered to the child with nearly fatal result. The pharmacist was fined for carelessness, an extraordinary pressure of duties being his only excuse. Nothing is said concerning the labeling of the bottles. Was this entirely omitted? The acid should at least have been labeled "poison," if sold at all without a prescription, and careful inquiry made as to its use. We had not expected such loose construction of the duties of pharmacists in the Austrian capital.—*West. Druggist*, October, 1887.

Medical Aphorisms.

A correspondent of the *Canada Lancet*, signing himself "Artz," says that he came across the following professional aphorisms of Amédée Latour, which are sufficiently curious and shrewd to merit reproduction:

1. Life is short, patients fastidious and the brethren deceptive.
2. Practice is a field of which tact is the manure.
3. Patients are comparable to flannel, neither can be quilted without danger.
4. The physician who absents himself runs the same risk as the lover who leaves his mistress: he is pretty sure to find himself supplanted.
5. Would you rid yourself of a tiresome patient, present your bill.
6. The patient who pays his attendant is but exacting, he who does not is a despot.
7. The physician who depends on the gratitude of his patient for his fee, is like the traveler who waited on the bank of a river until it finished flowing so that he might cross to the other side.
8. Modesty, simplicity, truthfulness! cleansing virtues, everywhere but at the bedside; there simplicity is construed as *hesitation*, modesty as *want of confidence*, truth as *impoliteness*.
9. To keep within the limits of a dignified assurance without falling into the ridiculous vauntings of the boaster, constitutes the supreme talent of the physician.
10. Remember always to appear to be doing something—above all when you are doing nothing.
11. With equal and even inferior talent the cleanly and genteely dressed physician has a great advantage over the dirty or untidy one.

Another Medical College.

Application was made to the Court of Common Pleas of Philadelphia, November 1, 1887, for a charter for the Burton Medical College Association, whose purpose is "to establish a college to be known as the Burton Medical College, and subsequently, in connection therewith, a hospital for clinical advantages."

New York Eye and Ear Infirmary.

The Directors of the New York Eye and Ear Infirmary are about to resume the work of raising funds for a new building. Subscriptions to the amount of \$60,000 are now on the book. As soon as \$100,000 is secured they will proceed with the erection of the east wing. The present building will remain in use exclusively for hospital purposes until it can be replaced by something better. The infirmary is the oldest institution of the kind in the country.

Quarantine Commissioners Stirred Up.

The quarantine commissioner of New York are much exercised over the report of a committee of the College of Physicians, of Philadelphia, which visited the quarantine station at New York, and found it entirely inadequate to the necessities of so large a port. Commissioner Judd in reply says: "We don't want any advice from Philadelphia, nor do we want any more opinions from medical men there or anywhere. In my opinion, the community have more to fear from doctors than from the cholera."

A Large Piece of Ambergris.

Charles Reade, in one of his novels, gives a graphic account of a lucky catch of a quantity of ambergris in the body of a sperm-whale, which was found floating on the ocean "as high as a frigate," dead of disease. David Dodd, the narrator of the story, states how, as his vessel approached the sperm-whale, the stench of the carcass became so intolerable that the skipper gave the crew leave to go below and close the lee ports, only remaining on deck himself with Dodd. They stuffed their noses and ears with cotton steeped in aromatic vinegar, and their mouths with pig-tail; they lighted short pipes, and broached the vessel upon the putrescent monster, and grappled to it. Then the skipper jumped on it, a basket slung to his back, and a rope fast under his shoulders, and drove his whale-spade in behind the whale's side-fin, digging a hole four feet deep. After a long search he gave a shout of triumph, and picked out some stuff that looked like Gloucester cheese, and when he had nearly filled his basket, returned on deck. Soon a heavenly perfume arose from the cheese-like stuff, struggling for mastery with the stench from the carcass. The stuff was ambergris—eight pounds of it—which the captain sold to a wholesale chemist at a guinea an ounce, clearing 128*l.* by the transaction.—*Chemist and Druggist.*

The Sale of Intoxicating Liquors by Druggists.

The *Western Druggist* says: The sale of intoxicating liquors by druggists in Michigan will be kept within strictly legitimate bounds if the law recently enacted on the subject is enforced with any degree of energy. As will appear from extracts published elsewhere, the minimum license for vending liquors is \$500 per annum, but this provision does not apply to druggists selling liquors for

"chemical, scientific, medicinal, mechanical, or sacramental" purposes, provided they make a detailed record of all such sales, and file a bond in the sum of \$2000, by which the signer agrees not to sell to a minor (except upon the written order of parent or guardian), nor to a person "in the habit of getting intoxicated," nor to any "Indian, or person of Indian descent," nor to any person when forbidden in writing to do so "by the husband, wife, parent, child, guardian or employer of such person," nor to sell any such liquor "to be drunk on the premises, nor to be mixed" with soda-water; that he will sell liquors only for the purposes before named, and then hold himself liable for all "damages, actual or exemplary," which result from such sales. For the first violation of any provision of the act, the minimum penalty is \$100 or ninety days' imprisonment, or both, in the discretion of the court; for the second offence, an additional penalty of forfeiture of all privileges under the law, for a period of five years.

Quackery on a Grand Scale.

The English journals contain an account of a most audacious quack who has recently had full swing in Paris. Some months ago the quack in question opened a splendid suite of rooms in a building on one of the Boulevards. He had footmen in plush and pages in livery, and advertised largely, announcing that he had an infallible cure for hoarseness and diseases in the throat by inhalation. He called himself Dr. Pitchitchine,—a name which had been culled promiscuously from an ordinary atlas, and at once began successfully an extensive scheme of deception. By and by a young actress, who had just accepted a six months' engagement, was allured by his representations to visit him to obtain relief from some laryngeal difficulty. The folding doors on her arrival were thrown open by a gorgeous attendant, and the great quack appeared before her gaze dressed in oriental garb. The head of the actress was enveloped by the quack in a cloud of cashmere, and she was told to inhale the contents of a tube. She did so, and instantly fainted away. The quack became alarmed, and at once sent for the nearest medical practitioner, who quickly revived the patient. The actress found herself subsequently hardly able to speak, and her voice so injured as to compel her to cancel her engagement, and the quack has been proceeded against for damages to indemnify the actress for the loss of her engagement, while he is also to be prosecuted

for illegal practice of medicine. The inhalation consisted of a mixture containing a large quantity of chloroform.

An English Opinion of American Dentistry.

America, that is to say the States, is the home of scientific dentistry. In no other country probably does one see so much gold utilized for stopping what might otherwise have been aching cavities as in the home of the sweet potato. Useful it undoubtedly is, but it is occasionally a positive disfigurement. Many Americans—especially among the female portion of the population—cannot laugh without the observer being startled by the metallic masses which excite at once his surprise and his cupidity. We have not heard so far of any murders directly attributable to the temptation to which the unwary traveler is thus exposed, but this absence of crime can only be attributed to the wonderful control that some people have over their itching palm. It is true that to pilfer a gold-laden tooth is a task requiring considerably greater dexterity than that of rifling a pocket, and the immunity of these brazen-teethed persons from robbery with violence is possibly due to this fact.—*Med. Press and Circular*, Oct. 12, 1887.

Antiseptic Duels.

A triumph of antiseptic surgery, which was probably unforeseen by Sir Joseph Lister, is recorded by the French papers. As is well known, the *duello* still flourishes among our neighbors with a vigor that would have delighted Captain Bobadil. As a rule, honor is very easily satisfied in these encounters, and all the scientific thrusts and lunges end usually in wounds which are well within the range of minor surgery. It appears, however, that in a recent affair of honor the principals, who "meant business," ran each other completely through the body. Great, therefore, was the amazement of their friends to see both the heroes of the fray walking about a few days afterwards as if nothing had happened. This fortunate result is attributed to the fact that the surgeon who was in attendance on the ground had taken the precaution to dip the swords in a strong solution of carbolic acid before they were used. This humane idea might possibly be still further improved upon, and the combatants might be compelled to fight in suits of antiseptic gauze and protective, and under a cloud of carbolic spray. The sterilisation of pistol bullets may follow, and impetuous politicians on the other side of the Channel will then be able

to indulge in their favorite recreation with even less risk than at present.—*Brit. Med. Journ.*, October 17, 1887.

Not a Medical Editor.

A sullen-looking man with a horsewhip entered a Nebraska newspaper office and asked the boy where the editor was. The boy "sized him up" and answered:

"Gone to Ohio; won't be back for six months."

"Where's the foreman?"

"He's gone to Washington with an invitation to the President. Won't be back 'fore cold weather. What do you want—want to paralyze 'em?"

"No, no; I owe them \$4 and thought I'd pay up."

"That so? hold on a second; perhaps the editor hasn't started yet."

He whistled; a long, dark form crawled out of a wood-box, and the editor was ready for business.—*Nebraska State Journal*.

Items.

—Dr. John M. Carnochan, a well-known surgeon in New York, died suddenly of apoplexy, October 29th. He was born in 1817.

—Dr. James Knight, Surgeon-in-Chief of the Hospital for the Relief of the Ruptured and Crippled, in New York, died October 24. He was born in Maryland, in 1810.

—The people of Musquodoboit Harbor and Jessore, in Nova Scotia, are terrorized by highway robbers and burglars. A few nights ago Dr. Stoddart, a well-known physician, had his wagon stopped by a highwayman, but escaped by applying the whip to his horse. The robber fired after him, but missed his aim.

—On Monday, October 24, Dr. Baker, of Bay-City, Mich., was sent for by one Joel Dietz, a travelling agent, who had developed symptoms of insanity. When the doctor arrived Dietz shot him twice with a revolver, and then shot himself through the heart. Fortunately the doctor was not seriously injured.

OBITUARY.

DR. MOSES GUNN.

Dr. Moses Gunn, of Chicago, the eminent surgeon, died November 4th, at his residence in that city.

Dr. Gunn was born in East Bloomfield, N. Y., in 1822. He graduated at Geneva

Medical College in 1846, and settled at Ann Arbor, Mich., and commenced practice. At the same time he instituted a course of anatomical lectures, the first systematic enterprise of that kind in Michigan. Upon the organization of the Medical Department of the State University, he was appointed to the Chair of Anatomy and Surgery, and occupied it for nearly eighteen years. He served in General McClellan's army during the war. In 1867 he succeeded Dr. Daniel Brainerd in the Chair of Surgery in Rush Medical College, Chicago.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Oct. 30, 1887, to Nov. 5, 1887:

Capt. Chas. B. Byrne, Assistant Surgeon, ordered for temporary duty at Ft. McHenry, Md. S. O. 231, Div. Atlantic, Oct. 28, 1887.

Capt. Curtis E. Munn, Assistant Surgeon, relieved from duty at Fort Canby, Wash. Ter., and ordered for duty as Post Surgeon at Fort Klamath, Oregon. S. O. 231, A. G. O., Oct. 28, 1887.

Capt. G. W. Adair, Assistant Surgeon, the leave of absence for seven days granted on the 27th inst. by the Commanding Officer, Fort Brady, Mich., is extended twenty-three days. S. O. 231, Div. Atlantic, Oct. 28, 1887.

List of Changes in the Medical Corps of the U. S. Navy, during the week ending Nov. 5, 1887:

Surgeon P. Fitzsimmons, ordered to the U. S. steamer "Marion."

Assistant Surgeon L. W. Atlee, ordered to the U. S. steamer "Marion."

Medical Inspector N. L. Bates, ordered to the U. S. steamer "Trenton."

Passed Assistant Surgeon Henry G. Beyer, ordered to the U. S. steamer "Trenton."

Assistant Surgeon Stephen S. White, ordered to the U. S. steamer "Trenton."

Passed Assistant Surgeon P. M. Rixey, detached from the U. S. steamer "Trenton" and await orders.

Passed Assistant Surgeon Richard Ashbridge, ordered to the U. S. Receiving Ship "St. Louis."

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Nov. 5, 1887:

C. S. D. Fessenden, Surgeon, detailed as Chairman of Board for the physical examination of officers of the Revenue Marine Service, Nov. 1, 1887.

F. W. Mead, Passed Assistant Surgeon, detailed as Recorder of Board for the physical examination of officers of the Revenue Marine Service, Nov. 1, 1887.

A. D. Bevan, Passed Assistant Surgeon, relieved from duty at Portland, Oregon; ordered to Marine Hospital, New York, Nov. 2, 1887.

INJURIES TO THE FÆTUS DURING LABOR.¹

BY THEOPHILUS PARVIN, M.D.,

Professor of Obstetrics in the Jefferson Medical College,
Philadelphia.

Though injuries of the child during labor are not frequent, probably they are much less rare than is commonly believed. In many instances they are not recognized immediately after delivery, and they may disappear spontaneously, and in some their consequences are attributed to erroneous causes. Some of these lesions may happen in spontaneous labor, and others in artificial, whether the interference be manual or instrumental. It is impossible to classify them according to their causes, and apparently their most satisfactory division is one resting upon the regions or parts affected. Hence, in the paper now presented, injuries to the fœtus in labor will be divided into those involving the head and neck, those of the trunk, and, finally, those of the extremities.

Injuries of the Head and Neck.

Contused wounds of the scalp and of the face, and incised, punctured, and lacerated wounds of the former are met with. So far as contused wounds of the face are concerned, it usually happens that they follow difficult delivery with the forceps, especially if the instrument be a powerful compressor; so too these result if the blades

are applied obliquely, or antero-posteriorly to the head, instead of to its sides. But in almost all cases the effects are trivial and soon disappear. Punctured and incised wounds of the scalp have been made from mistaking a caput succedaneum for the fœtal sac. Tarnier mentions an instance of a wound thus inflicted leading to the death of the child from erysipelas, a few days after birth. More extraordinary is a lacerated wound of the scalp, made in the effort to apply forceps, the operator introducing one of the blades between the scalp and the cranial bones. An example of this terrible blunder is mentioned by Charpentier, and I have met with a similar case.

Sloughing of a portion of the scalp has been observed following some cases of spontaneous labor. Thus, Priestley¹ has reported a case of this kind, resulting in death eight days after delivery; the labor was protracted for forty-eight hours because of a narrowed pelvic outlet. Lizé,² of Mans, states that in the case of a multipara, forty years of age, the bag of waters ruptured five days before the birth of her child, which presented by the vertex, but occupied an occipito-sacral position. Five days after delivery, a slough involving almost the entire extent of the occipital bone appeared; three days subsequently it became detached and the child recovered. Bouchut³ quotes from Lorain a case of gangrene of the scalp in a new-born child occurring in the service of Moreau. The mother was a primipara, and the labor lasted forty-eight hours, terminating sponta-

² *Annales de Gynécologie*, 1875.

³ *Traité pratique des Nouveau-Nés*, etc.

neously; the child died on the nineteenth day. Dr. Goodell informs me of a case in which an oblique application of the forceps was made—one blade being in relation with the right frontal bone, and the other with the left occipital—and the right anterior portion of the head was so bruised that sloughing occurred a few days after birth. After the detachment of the slough, a fatal hemorrhage occurred.

Depressions and fractures of the cranial bones, separation of their union to each other, fractures of the bones of the face, as well as disjunction of their articulations and joints, have been observed more or less frequently in cases of difficult labor, manual or instrumental—some of them, indeed, in spontaneous labor. Some obstetricians have asserted that depressions of the bones of the foetal skull are always accompanied by fractures. This was the opinion of Danyau, of Lachapelle, and of Schröder. But a case,¹ given by Matthews Duncan, seems to strengthen the view held by most obstetricians, that such depressions may occur without the bone being broken. The case was one in which a persistent impression was made on the right parietal bone, by the finger of the accoucheur, who was endeavoring to cause rotation. The result was slight, short, but frequently repeated epileptiform seizures, which lasted some time after the impression had disappeared, and were finally replaced by choreic movements. It seems hardly probable that the pressure of the finger produced a fracture of the bone.

Dugès² has given an instance of great depression in one of the parietal bones, not followed by any serious consequences. The child was delivered by the feet through a pelvis of which the conjugate diameter was estimated at three inches and a quarter. Powerful traction upon the shoulders and upon the lower jaw was necessary to bring the head past the obstruction, and the parietal bone, which was in relation with the sacro-vertebral angle, presented a depression half an inch in depth and two inches in breadth. The infant was resuscitated with difficulty, then had convulsions, but in a few days was quite well, and in fifteen days the depression had entirely disappeared.

Minor depressions or indentations are sometimes seen, especially after the application of the forceps, and in rare instances such marks are permanent. But we must not be in haste to conclude that these indentations,

found upon the head of a newborn child, are proofs of instrumental delivery, for Oslander¹ has stated that, having delivered a child by podalic version through a narrow pelvis, he found upon its head a depression into which the end of a forceps-blade accurately fitted; so that he himself would have concluded, had he seen a similar depression, that the delivery had not been spontaneous, but by the forceps.

Fractures of the foetal skull have been observed as the result of direct violence, as when a woman expels her child while she is standing, and it falls on the floor. Or, again, a woman,² near the close of the second stage of labor, the child's head being at the vulvar opening, threw herself out of the window, and several fractures of her limbs, as well as a fracture of the child's head, resulted. But apart from these cases in which the injury has resulted from direct violence, and those observed in delivery, whether spontaneous, manual, or instrumental, in narrowed pelves, which will be referred to in a moment, fracture may occur when the labor is in all respects perfectly normal, so far as duration and facility are concerned. Thus, Dr. Charles West³ has reported a case of an infant dying from convulsions nine days after birth, the labor having been an easy one and lasting but five hours. The mother had previously given birth to two living children, and these labors too had been normal. Yet, at an autopsy of the third child, a fracture of the right parietal bone was discovered, with effusion of blood between the cranium and dura mater, the effusion being more than half an inch thick and occupying the entire fossa of the bone. Dr. West states in his report that fractures of the skull have been known to take place during easy labors, and wholly independent of any preternatural degree of ossification of the skull. Monteith¹ mentions having attended a case of perfectly natural labor, in which the child had a fracture of the right parietal bone. There was a marked depression in the middle of the bone, and the fracture extended to the sagittal suture on one side, and to the coronal on the other. It is quite apparent that a case such as either of these might give rise to

¹ Given by Cieslewicz, *Verletzungen des Fœtus durch den Geburtshelfer*. Halle, 1870. Cieslewicz gives forty cases of fracture, fissure, contusion of nerves, laceration of muscles, separation of epiphyses, etc., occurring in labor; he also reports two of rupture of the longitudinal sinus.

² Quoted by Delore. *Fractures du Fœtus*, *Dictionnaire Encyclopédique des Sciences Médicales*.

³ *Transactions of the London Medico-Chirurgical Society*, 1845.

¹ *British Medical Journal*, October 18, 1873.

² Quoted by Jacquemier, *Manual des Accouchements*. Paris, 1846.

medico-legal investigation, or to unjust censure of the obstetrician.

In regard to fracture of the bones of the cranium or face, or rupture of the joints of the maxillary symphysis, or of the cervical vertebræ, or fracture of a vertebra—for it is claimed that usually the body of one is broken rather than two vertebræ are separated, as the consequence of great traction occurring in manual or instrumental delivery—an important question arises as to the amount of force which may be safely used either with hand or instrument. In illustration of the great force which has been employed in forceps delivery without injury to mother or child, I quote the following from Dr. Peugnet.² He states: "I was called to Mrs. K., a multipara, in labor with her third child. The first two were delivered by craniotomy. The vertex presenting, R. O. A., and impacted between the sacrum and the pubes, the conjugate diameter of the superior strait greatly contracted, I applied forceps, and had great difficulty in locking them. Dreading the laceration which might ensue in this case from side-to-side lever action, I concluded to rely upon direct and steady traction. My strength giving way, her husband held me round the waist, whilst the patient was held *in situ* on the dorsum by four women. In forty-five minutes I had the satisfaction of bringing the head down upon the perineum. The delivery was then speedily accomplished. Both mother and child, a girl, did well." The least that can be said in regard to this case is, that the result was very remarkable, and it is doubtful if the practice pursued could be repeated in any considerable series of similar cases without injury to both mother and child.

Delore,³ after remarking that the foetal head may endure, without injury, a great compressing force if applied to a large surface, and if made by a regularly concave surface, as that of the blades of the forceps, states that from his experiments he found a compressing force of one hundred kilogrammes (250 pounds) did not cause a fracture. But, on the other hand, if the blades slip, if the pressure is made upon a small surface, fracture follows the exercise of much less force. Further, a blunt, angular body, such as the sacro-vertebral angle, the spherical surface of which is described by a radius of two or three centimetres, produces a fracture with a force of twenty kilogrammes (50

pounds). As the force which is exerted in difficult labor is more than twenty kilogrammes (50 pounds), fracture results. Nevertheless, these results are not in complete accord with those of Goodell,¹ though, as will be seen, he is discussing the question of the amount of traction force that may be used in a narrowed pelvis without injury to the neck of the child. Nevertheless, the subject of injury to the bones of the head is also involved, and in only one instance, I believe, does he mention fracture of one of the cranial bones. He states that he has on several occasions delivered living children after throwing on their necks a weight of 130 pounds. He further says that, although exerting all the manual strength at his command, he has never seen the body part from the head. He mentions one instance in which there was not the slightest apparent injury to the neck, though the sacral side of the head had been broken in. Further, in another case, the force of traction upon the child's head, combined with suprapubic pressure, amounted to 200 pounds. Stone² has more recently reported a case of podalic version, and delivery by traction through a narrowed inlet, in which he put on the neck of the child all the force of which he was capable, using the pump handle movements described by Goodell. The child was dead. There was no fracture of the bones of the head. The spine had parted in the upper dorsal region during the traction upon the trunk, which was necessary to cause the shoulders to come low enough to reach the arms. The cervical spine was not broken.

Delore's conclusion as to the amount of force followed by fracture of the cranium of the foetus is erroneous, or such injury ought to have been observed in all cases where a force even approaching 100 pounds was used. Champetier's³ investigations as to the force that could be safely used in the delivery of the foetus, led him to the following conclusions, the first of which does not correspond with the results obtained by Goodell: First, there is danger of fracturing one of the parietal bones, whatever the method of extraction, if the total force employed reaches thirty-five to forty kilogrammes (87-100 pounds), the infant being at term, twenty to twenty-two kilogrammes if it be premature. Second, the inferior maxilla of a child at term will bear, without rupture, a traction of twenty-five kilogrammes (62½

³ Du passage de la tête foetale a travers le détroit supérieur rétréci du bassin.

pounds). Third, the vertebral column of an infant at term was ruptured in three cases by a force of fifty kilogrammes (125 pounds).

If it is objected that these results have been obtained by experiments upon dead children, and, therefore, are not applicable to the force which may be exerted upon living ones, the answer of Matthews Duncan may be repeated. He, after consulting physiological and physical authorities, could say that a child living and one recently dead were the same as to tensile strength.

In this connection it is well to refer to the amount of traction which may be safely applied to the lower jaw of the fœtus, as stated by Duncan¹ from his own experiments. It will be observed that his results are not the same as those announced by Champetier. Duncan states: "It is now ascertained that a force of half a hundred weight (fifty-six pounds) may, at least in some cases, be applied by dragging the lower jaw of the fœtus without producing any easily discovered injury of parts." He further says, that compound dislocation would be almost certainly fatal, and in one of his experiments this injury was inflicted by a weight of fifty-six pounds. Not only does Duncan's statement as to the force which the inferior maxilla will bear without injury differ from that of Champetier, but the difference is still greater from that given by Delore, who makes this forty kilogrammes (100 pounds).

Fractures of the cranium usually involve the parietal bones, but they may also occur in the frontal, in one of the temporals, or in the occipital bone. Jacquemier first pointed out the separation between the squamous and the basilar portion of the occipital bone, to which some more recent writers² have directed attention without giving him just credit. He also stated that he had met with fracture of the occipital bone, above the protuberance. Ruge,³ referring to separation of the epiphyses between the squamous portion of the occipital bone and the articular part, states that Schröder is the only one who has recently drawn attention to it; and, notwithstanding its importance in regard to the life of the child, this lesion is not referred to in classic works as one of the immediate consequences

of extraction. The lesion may also occur in a narrowed pelvis, though the head present. In these cases there may be not only effusion of blood, but further compression, from the squamous portion having its anterior inferior margin forced against the medulla.

On the other hand, severe injury of the frontal bone has been observed without serious consequences. Thus, Dugès¹ saw a child recently delivered, whose left eye was almost completely outside the orbit, so great was the depression of the frontal bone; yet the infant did not have convulsions or any other grave symptoms. I have seen protrusion of the eyeball in a newborn child, following fracture of the frontal bone by Hodge's forceps, in a case of tedious labor in a primipara, the delay being from an occipito-sacral position. The child lived for a week. That an infant may survive very grave injuries in labor is proved by a case reported by Lamotte,² in which a surgeon, in a case of shoulder presentation, had torn away the arm, and then performed a craniotomy, evacuating a large amount of the cranial contents; yet the child was born alive.

Zweifel³ regards fissures and fractures of the cranial bones as of clinical significance only if a sinus be injured and consequent hemorrhage occur. On the other hand, Delore⁴ asserts that all these fractures are grave, on the ground that they may be accompanied by contusions of the brain. Further, there may be hemorrhages between the bone and the periosteum, in the cavity of the arachnoid, or between the pia mater and the brain. If the solution of continuity be at the position of a sinus, there is frequently rupture of the vessel. He adds that in all cases in which the head has undergone severe compression from dystocia, he believes hemorrhages occur. The significance of this last remark will be appreciated, especially when we consider the remote consequences upon the mental condition of the child, as urged more especially by some English observers.

Injuries to the bones of the face are usually of the inferior maxilla. This bone may be fractured, or separation of the mental symphysis may occur. Ruge mentions cases in which, in addition to injury of the bone, there were lesions of the soft parts—as, for example, tearing of the skin at the angle of the mouth, as well as of the mucous membrane of the pharynx, and rupture of the

genio-glossus muscle. Yet, if we fail to use traction upon the lower jaw in cases of difficult head-last labors, we miss what may prove an important means of delivery when other means fail. Some years ago, in a case of narrow pelvic inlet, having failed to deliver with forceps, I performed podalic version, and sought to deliver by traction, while a consultant aided me with suprapubic pressure. I am confident that I did not use the force which some operators have employed safely under similar circumstances; yet the cervical vertebræ gave way, either by separation or by fracture, and I found apparently nothing but the integument holding the head to the body. I then succeeded by traction upon the inferior maxilla, suprapubic pressure assisting, in bringing the head into the pelvic cavity.

That the head may be left in the uterus, the body being dragged away, is a fact proved by occasional instances in the history of obstetrics. In other cases the division had been made, not by rupture, but by cutting through the neck. An instance is reported¹ in which the obstetrician, failing to deliver the head in a case of shoulder presentation, after detaching the arm and bringing down the feet, performed decollation, and the head and the placenta remained in the uterus for forty days. Freund mentions a case in which the head was left in the uterus for ten years.

Probably the most remarkable case of multiple injuries to the face has been recorded by Petit.² The face presented, rupture of the uterus occurred, and the woman died undelivered, though the forceps had been used. The autopsy of the child showed multiple separations of the bones of the face, and fractures.

Paralysis of one of the facial nerves has been observed most frequently, but not exclusively, after the use of the forceps. In a paper read before the American Gynecological Society in 1885, I referred to eight cases of spontaneous facial hemiplegia, and also mentioned one case observed by Seeligmüller, in which the paralysis affected both sides of the face. But the disorder usually occurs from the use of the forceps, and is caused by the pressure of one of the blades at the stylo-mastoid foramen, or a little in front of the lobe of the ear. Landouzy, who has best described this affection, has remarked that in the infant the complete absence of the mastoid apophysis and the slight development of

the auditory canal, favor compression of the facial nerve near its point of emergence. According to Parrot and Troisier, recovery usually takes place in six weeks in paralysis of the facial nerve caused by the forceps. Many cases, however, get well in ten days. Nevertheless, while recovery is the rule, it should be remembered that in some cases the injury is permanent. Duchenne¹ refers to two patients, one fifteen years old, and the other five years and a half, in each of whom the paralysis continued. It should also be observed that there may be facial paralysis in the newborn, caused by protracted labor and intracranial hemorrhage.

Injuries of the sterno-cleido-mastoid muscle have been observed by several practitioners. Torticollis, of obstetric origin, is explained by Stromeyer and Dieffenbach as resulting from improper application of the forceps, the muscle being bruised or torn. But this explanation is rejected by Saint-Germain as not plausible. A very large proportion of infants that have wry-neck are born with pelvic presentation, and it is asserted that the traction exerted causes rupture of some fibres of the muscles; a hæmatoma follows, and, finally, contraction of the cicatricial tissue results in drawing the head into an unnatural position. One of the first references to tumors of the sterno-cleido-mastoid was made by Melchiori² in 1862. He spoke of them as indurations of muscle, sometimes met with in young infants, and to which he found no reference in authors. He met with this disorder four times, and he described the affection as an indurated, plastic deposit. While he mentions temporary deformity of the neck, he does not speak of any case in which this was permanent. In referring to its etiology, he suggests that compression of the muscle, or laceration of some of its fibres, may take place during labor. The next year both Dr. Wilks and Sir James Paget³ met with cases of what they described as chronic induration of the sterno-cleido-mastoid. Another case of the affection was reported the same year by Dr. Harris; and thus the published cases in a few months numbered at least six. But no reference was made by any of the reporters to the previous observations of Melchiori.

Bryant,⁴ in 1863, reported two cases of thickening of the sterno-cleido-mastoid.

² *Annales de Gynécologie*, 1874.

One patient was four, the other eight weeks old, when he saw them. In each instance the birth was with pelvic presentation. Probably in all the cases, or at least in a majority of them, the disease was hæmatoma. Nevertheless, Blachez¹ regarded these tumors as caused by an interstitial myositis, in consequence of traction upon the muscle. He describes the tumor, observed in one of his patients, as elastic, almost painless, and the size of a pigeon's egg; it was situated in the right sterno-cleido-mastoid, and was not discovered until two or three weeks after birth, when the attention of the parents was called to it by the infant's keeping the head inclined to the right side. Zweifel recognizes injuries of the sterno-mastoid muscle in labor as a cause of torticollis. Professor Albert,² of Vienna, referring to a child with torticollis, stated that the sterno-cleido-mastoid may become contracted during intrauterine life, or be injured during birth. In breech presentations, and in difficult forceps delivery, a laceration of this muscle may occur, and be followed by inflammation and contraction.

While such injury is more frequent after head-last labors, yet they are also met with in vertex presentations, and if the forceps have been used.

Injury to the brain.—On October 2, 1861, a paper was presented to the London Obstetrical Society by Dr. Tyler Smith for Dr. W. J. Little, the title being "Upon the influence of abnormal parturition, difficult labors, premature birth, asphyxia neonatorum, on the mental and physical condition of the child, especially in relation to deformities."³ In this paper—which by the way mentions two cases of wry-neck, attributed to difficult labors—the author says: "It is impossible not to connect the persistent affections of the intellect, of volition, and of organic life, with the injury the several nervous centres, suffered in some instances before the fœtus had reached the maternal pelvis; in others whilst in transit through it; and in a third set of cases, where the fœtus was exposed to neither of these kinds of injury, it suffered from asphyxia neonatorum, suspended animation, and its concomitant congestions, effusions, capillary apoplexies of the brain, medulla oblongata, and spinal cord." Dr. Langdon Down, in discussing the obstetrical aspects of idiocy, stated that in a very large number of cases of idiocy the subjects were born after difficult and unusually tedious

labors; and he held that if a neurotic tendency was present the tedious labor and suspended animation might determine the catastrophe, where otherwise all might have gone fairly well.

The following note from one of Dr. Little's¹ correspondents may be of some interest; it is in reference to a young man in regard to whom inquiry had been made by Dr. Little: "I have again ascertained he was asphyxiated for two hours when born, and that he has always been a weak creature; very slow in mental development; with difficulty in speaking; trembling and shaky; unable to fix his attention on a book; and a bit of a punster." The final statement, "a bit of a punster," is conclusive as to the intellectual feebleness of this unfortunate man! These views are further strengthened by the statement of Dr. Arthur Mitchell,² that he believes there is a connection between difficult labor and idiocy.

Injuries of the Trunk.—The chief lesions of the trunk are: rupture of the connections between the dorsal vertebræ, or fracture of one of these; injuries to the abdominal wall by a badly directed blunt hook; effusion of blood in muscles, similar to those that have been referred to as occurring in the sterno-cleido-mastoid; retropleural hemorrhages along the spinal column in case rupture of this column occurs; hemorrhage into the abdominal or thoracic cavity; collections of blood beneath the capsule of the liver, or of the kidneys; and rupture of the sacro-iliac joint. Ruge has collected forty-four cases of injury to the fœtus occurring in extraction after version, and twenty-nine of injuries in pelvic presentations. In the former there are three cases of rupture of the sacro iliac joint. It is probable, as suggested by Zweifel, that some cases of ankylosis affecting this joint, of which the etiology is obscure, are to be attributed to injury in birth. Zillner³ has reported a rupture of the sigmoid flexure occurring in labor.

Injuries of the Arms.

In connection with these lesions those of the scapula and clavicle, which belong to the arms rather than to the trunk, will be considered. Delore states that *fractures of the humerus* are more frequent than all others, as they are usually readily cured, and are generally caused by *mal-adresse*; they are rarely published. But he further says that this accident may occur in the hands of the most expert

¹ *Gazette Hebdom.*, May 19, 1876.

accoucheur, if the pelvis be contracted. They occur most frequently in the disengagement of the arms after podalic version, when extraction is necessary; and they may also happen in pelvic presentation, but usually, if we do not have to extract the child—that is, if the expulsion can be left solely to nature—the arms will not ascend, but remain applied to the chest. Smellie¹ states that he fractured the humerus in a case in which he turned, and delivered by the feet. This is the only case he gives, while he mentions three cases of fracture of the femur, two occurring in the practice of his assistants, and one in his own.

All obstetricians agree that in bringing down an ascended arm it is important that no pressure be made until the internal angle of the elbow is reached, and that three or four fingers should be employed, and not one or two. Pajot regards it as important that the posterior arm should be liberated first. Küstner² describes separation of the epiphysis of the head of the humerus from the diaphysis as one of the injuries of labor which may be overlooked, or falsely regarded as a luxation, a fracture of the neck of the scapula, or an injury to nerves. Fractures of the clavicle, separation from its sternal attachment, transverse fracture of the scapula, separation of the epiphysis of the neck of the scapula, injury of the acromion process, and dislocation of the humerus, have been observed.

Fracture of the Clavicle is most frequently caused by pressing directly with one or two fingers, in the endeavor to bring the head through the pelvic inlet after podalic version, or in pelvic presentation. McClintock, in one of his annotations to the

Sydenham Society's edition of "Smellie," observes, "Although Smellie gives no example of fracture of the child's clavicle during delivery by the pelvic extremities, yet, in my experience, it is a bone very apt to be broken by the manipulations of the accoucheur, more so even than the humerus; this may, perhaps, be explained by its greater degree of ossification."

Paralysis of the Arm.—Sinkler recognizes hemiplegia as, in some cases, the consequence of injury at the time of birth, either from the forceps or from the pressure of a prolonged labor. Nadaud gives seven cases of paralysis of the arm attributed to the forceps; the first case of this injury reported is one of Smellie's. Jacquemier mentions an instance of paralysis of the deltoid following a long and difficult, but spontaneous, labor; the recovery was complete in fifteen or twenty days. He attributed the disorder to compression of the axillary nerve against the humerus at the point of its attachment to the deep face of the deltoid. Fasbender found a tumor, as large as a pigeon's egg, situated above the right clavicle, in an infant soon after delivery; the hæmatoma gradually disappeared, but at first there was paralysis caused by nerve compression. Delore suggests that paralysis may be caused by the rupture of a nerve trunk near its connection with the spinal cord. He states that this accident is not rare in the new-born, or in young infants, as a consequence of traumatism; it is followed by incurable paralysis, which is compatible with life if an upper member only is affected. Disengagement of the extended arms in pelvic deliveries, and traction upon the axilla in delayed delivery of the body in vertex presentation—the traction in some cases being with the blunt hook, in others with the finger—have resulted in paralysis of the arm. The same disability has occurred in a case in which the arm protruded in shoulder presentation and delivery was effected by podalic version.

Luxation of the humerus has, in some instances, been mistaken for obstetric paralysis. Further, it is important to distinguish between cerebral and traumatic paralysis. Duchenne¹ gives an instance in which there were both cerebral and obstetric paralysis, the latter consequent upon a fracture of the ulna near the elbow.

Injury to the Legs.

Fracture of the femur may be spontaneous, or consequent upon artificial delivery.

¹ Sydenham Society's edition of Smellie's Midwifery, vol. iii., pp. 296, 297. This great obstetrician, in the first volume, remarks: "In laborious or preternatural cases, when considerable force hath been used in delivering the child, the whole body ought to be examined, and if there is any mark or contusion on the head, it will disappear if anointed with pomatum, and gently rubbed off or chafed with the accoucheur's hand; if any limb is dislocated or broken, it ought to be reduced immediately; luxations, though they seldom happen, are more incident to the shoulder than to any other part, the humerus being easily dislocated, and as easily reduced. The ones of the arm and thigh are more subject to fracture than any other of the extremities; the first is easily cured, because the arm can be kept from being moved, but a fracture of the thigh-bone is a much more troublesome case, because over and above the difficulty of keeping the bones in a proper situation, the part is often necessarily moved in cleaning the child."

² Ueber die Verletzungen der Extremitäten des Kindes.

¹ See Nadaud, op. cit.

Meyer has recently¹ reported two cases in which spontaneous fracture of the femur was observed; in one a single femur was broken; in the other both femurs. In May, 1847, Dr. Vanderveer² reported a case of such a fracture in childbirth. But probably more fractures of the femur are to be attributed to the attempt to pull down a lower limb in pelvic presentation, when the presenting part is already partially in the mother's pelvis, before pressing up the presenting part, or from the use of the blunt hook. Delore's experiments show that with the untied finger traction to the amount of fifteen kilogrammes (37 pounds), may be made upon the groin, and this cannot break the femur. If a force of fifty-five kilogrammes (137 pounds) is exerted upon the femur, fracture occurs; if the instrument be perpendicular to the bone, the latter gives way with a pressure of twenty kilogrammes (50 pounds).

Again, the femur has been broken, or separation of the epiphyses has been caused, by traction upon the leg. A. R. Simpson mentions an instance in which podalic version was performed, the right lower limb brought down, and traction made. Subsequent examination showed that there were three fractures of the femur.³

Luxations of the femur, consequent upon obstetric operations, are exceedingly rare according to Ruge. In 300 autopsies upon new-born infants, he did not find a single true dislocation of this bone. Küstner, in referring to luxations of the hip, speaks as follows: "Göschel relates a case in which Langenbeck reduced such a luxation after the subject, a girl, was thirteen years old, and mentions in this connection that Stromeier had met with twenty cases. The only possible way in which this injury could occur would be by sudden and violent force drawing down the limb, and then dislocation upon the ilium might result. But the force must be great. I have suspended to the leg of a child, from six to ten minutes, a weight of from thirty to forty kilogrammes (75-100 pounds), without any injury to the joint."

Complete paraplegia, in connection with facial paralysis of the right side, has been observed following a difficult labor in which the forceps were used. Examples of rupture of the spinal cord, in connection with rupture of a vertebra, have been observed, and, of course, paralysis of the lower limbs. It is

remarkable that, in two such cases the children lived for some hours. Paraplegia in the new-born is, as Nadaud states, usually an evidence of serious lesion of the cerebro-spinal organs, and the child dies after a short time.

I think the study of these cases of obstetric injuries, which might be greatly extended—for much more remains unsaid than has been said—ought, in the first place, to lead us to a larger charity for fellow practitioners, as many of the most serious injuries in childbirth may occur without the slightest blame necessarily attaching to the accoucheur. Another lesson is that an important distinction should be made, as urged by Ruge, between podalic version and extraction, and that we should never resort to the latter, unless absolutely necessary, after the performance of the former. Thereby many of the obstetric lesions of the fœtus may be avoided. Lamotte very wisely says, referring to the injuries which may be done to the child by the accoucheur: "The hand improperly used is more dangerous than any instrument."

Again, the question arises as to the safest manual means for the delivery of the head in head-last labors. In Cieslewicz's collection of cases of injury to the fœtus in labor, there are several in which very serious consequences resulted from employing the Prague method. One of these, reported by Güsserow, showed, upon post-mortem examination, such complete rupture of the vertebræ and most of the soft parts of the neck, that the head was attached to the trunk only by the skin and the vertebral arteries. Ruge, rejecting both the Prague and the Vienna method, prefers elevation of the occiput, bringing the face down, and carefully conducted expression, as least liable to injure the fœtus.

Another question of practical interest is the best method of delivery in pelvic presentations, when interference is necessary. Should we follow that employed by Goodell, in all cases bringing down a foot as soon as possible, and thus command the situation, in case necessity for extraction arises? Must we use the blunt hook? Is the application of the forceps to the breech to be generally advised?

Again, while treatment of fractures of an upper limb, or of the clavicle, is said to usually present no great difficulty, can a similar statement be made as to fracture of the femur? What method of treatment is best?

In depressed fractures of the skull, is it

¹ *Archiv. f. Gynäkologie.*

² *New York Medical Journal.*

³ *Edinburg Med. Journ.*, 1880.

not probable that some lives might be saved by the use of the trephine? and in other cases, not followed by death, perfect mental integrity be insured?

Finally, many questions as to the diagnosis of obstetric paralyses of the new-born arise, and, also, as to when and what treatment should be employed.

EXPERIENCE WITH VERATRUM VIRIDE.

BY A. ADY, M.D.,
MUSCATINE, IOWA.

The editorial on veratrum viride, in the REPORTER of October 29, prompts me to narrate my experience with this drug. I have been using it for thirty-four years, and it has disappointed me fewer times than any other medicine. In proper doses, I do not believe that it has any tendency to weaken the heart. On the contrary, by slowing its contractions, it gives that organ time to rest and recuperate. As a heart tonic I consider it equal, or superior, to digitalis; as a controller of the heart and arteries, superior to all other remedies in use.

In all inflammatory disorders in which the action of the heart is too strong and frequent, it is superior to blood letting. In acute pleurisy and pneumonia, when a patient is brought thoroughly under its influence, he is about cured. The cumulative effects of veratrum viride are not dangerous, as they are relieved by vomiting, after which the patient will almost invariably ask for something to eat.

In typhoid fever veratrum viride is one of the best of remedies. Thoroughly unloading the stomach and portal circulation, controlling the circulation, preventing the tongue from becoming dry and parched. I feel sure, also, that in many cases it has shortened the course of the disease. Patients eat well while taking veratrum viride. The doses in these cases must be small, one drop of Norwood's tincture every four hours being often sufficient.

In puerperal convulsions it is a most efficient remedy, but must be given in very large doses, the uræmic condition producing tolerance of its effects. A patient in puerperal convulsions can safely take from thirty to sixty drops of the fluid extract. I have not been obliged to repeat the dose in such cases, nor has vomiting occurred.

In membranous croup it is *the* remedy; but must be given for effect, not in ordinary

doses. I have given a child two-and-a-half years old, twenty drops of the fluid extract inside of six hours, with the best results. It is worse than useless in diphtheria, scarlatina, and pyæmia.

I have used it in small-pox, bringing the patient under its influence in the initial fever, and not allowing the pulse to rise above sixty beats per minute during the course of the disease. In this case no delirium occurred, nor any secondary fever, and when the crusts dropped off no pitting of the skin was left. Dr. Maxwell, of Davenport, now dead, confirmed my experience, after ample opportunity to test it in the army pest-houses during the war. He also claimed that, if the drug was administered during the course of vaccination, no scar would be left.

The only unpleasant symptoms, which I have witnessed in the use of veratrum viride, have been nausea and vomiting, and according to Prof. H. C. Wood (*Amer. Journ. Med. Science*, vol. 49, p. 30), they can be entirely avoided by separating the alkaloid containing the sedative principle from that of the emetic, as was done by Mr. Chas. Bullock, of Philadelphia, with the article experimented on by Prof. Wood.

I have been trying for the last fifteen years to get some pharmacist to prepare and put the viridæ sulphas upon the market. It certainly would be extensively used, especially by the practitioners of the west.

In conclusion, I would say that, if I had to rely upon four articles for an armamentarium, they would be quinine, calomel, opium, and viratrum viride.

A CASE OF GANGRENE OF THE LUNG COMPLICATING CROUPOUS PNEUMONIA.

BY THEODORE DILLER, M.D.,
LANCASTER, PA.,

Member Lancaster County Medical Society, formerly
one of the House Physicians to Phila. Hospital.

Charles Manlove, colored, age 35, was brought to the hospital in an ambulance, June 6, 1887. He was taken from one of the lowest dens in St. Mary street, where he was found in a condition of squalor and filth. The following history was obtained: He had had the ordinary diseases of childhood and typhoid fever, and for many years had been a very hard drinker; but had considered himself a healthy man, and had worked up to May 24, 1887, on which day he was seized with

a severe pain in his left chest from the nipple downwards. He said he felt very feverish about this time, and expectorated a considerable amount of tenacious, viscid material, which at first was brownish in color, latterly, yellowish white. His sleep was very irregular, and he complained of sweating a great deal during sleep. Up to this time (June 6, thirteen days after the initial chill), he had had no medical attendant, and indeed very little attention of any kind. After being placed in a medical ward, a physical examination was made by Dr. Bruen and me, which showed the resonance over the right chest to be impaired from the fourth rib downwards, and the tactile fremitus correspondingly increased. Over this area of impaired resonance numerous râles were heard and some blowing breathing. The same physical signs were elicited over a corresponding posterior area.

Anteriorly, just below the clavicle (on the right side), the presence of a considerable sized cavity was discovered, by means of the ordinary physical signs. The patient's breathing was hurried, his pulse quick, but lacking in force, and there was a peculiar *pinched* appearance about the face. His breath was exceedingly fetid; so much so that the other patients in the ward complained bitterly of it. I was forced on this account to isolate him. His treatment was a stimulating and supporting one, consisting of amm. carb., tr. digitalis and whiskey—the last was given very largely, while nourishment was given at short intervals in a concentrated and easily digested form. A spray of carbolic acid solution (1 to 60) was used as a local application by means of an atomizer, with the view of rendering his breath less offensive. This measure was in a large degree efficacious. Patient died June 11th.

An *autopsy* was made, twenty-six hours after death, by Dr. H. F. Formad, assisted by me. The following notes were taken: Body that of a colored man of medium height, considerably emaciated. Heart normal. *Pleura* on right side very adherent, from the apex to the fifth rib.

Right lung crepitant at the extreme apex, the remainder of the upper lobe being in a state of gray hepatization. The two lower lobes are in a state of red hepatization passing into the gray. In the upper lobe there is a cavity about the size of an orange, situated anteriorly and just below the pleura, but in no place perforating it. The walls of the cavity are very ragged and irregular, while there is surrounding the cavity a hard, indurated mass of gray material. Several

good sized vessels are seen crossing the cavity. The odor emitted is horribly offensive, and there is a blackish, semi-fluid material contained in it.

Left lung crepitant throughout, except at the base, which is in a state of hypostatic congestion.

Other organs not examined.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, October 26, 1887.

The President, J. Solis Cohen, M.D., in the Chair. The discussion on Dr. Parvin's paper¹ on

Injuries to the Fœtus During Labor

was opened by Dr. W. T. Lusk, of New York, who said: Dr. Parvin, in his exhaustive *résumé* of the subject, has said that we should exercise charity toward those under whose care these accidents may happen. At the same time, I think we should, as scientific men, look upon this record as most humiliating, and should ask ourselves if we should exercise this charity toward ourselves as individuals, should these accidents fall to our lot.

I wish to avoid a repetition of the points which have been already so ably presented. In going over the subject there may, however, be found one or two matters which have been overlooked, or which it might be well to make more emphatic. In speaking of fractures of the skull occurring in spontaneous deliveries, cases which occurred many years ago have been given. In modern times reports of fractures in head-presentations terminating without the intervention of art are very rare. My attention has been called to one such case reported by Veit. The patient had received large doses of ergot. When the child was expelled it was found that the right parietal bone was separated from its fellow, from the occipital, and, to a great extent, from the frontal bone, and two fractures were found in the bone itself. It is a question, whether the cases of spontaneous fracture reported many years ago were due to the abuse of this certainly most unreliable drug?

I saw last summer a very interesting case of depression of the skull following a rather easy forceps delivery. I was sent for because

¹ See page 663.

the question had arisen between two practitioners as to the advisability of trephining the skull—introducing an instrument and elevating the depressed bone. I am not sure that this might not be good practice in some instances, but so far we have had no experience as regards results. We know that if the child shows no immediate symptoms from the depression, it is likely to thrive, and that in time the depression nearly or entirely disappears. In the case above referred to we decided to wait, the child has been thriving since, there is still a quadrilateral depression in the frontal region, which has not entirely disappeared. I was quite certain that the mother of this child had a contracted pelvis with projection of the promontory; but, in making an examination some three or four weeks after the birth of the child, to my surprise, found that the woman had a fairly roomy pelvis. The antero-posterior diameter measured at least three and three-fourths inches. The only conceivable cause of the depression was the blade of the forceps. This was to me certainly a novelty.

With reference to the amount of force which may be exerted on the neck of the child, I think that if we rely upon the experiments to which reference has been made, we are likely to be led into error. There is no doubt that the resistance of the neck under pressure varies greatly in different subjects. While the neck of one child will bear a weight of 160 pounds, the vertebræ of another will separate under a much less amount of tension. I do not believe that there are ever circumstances in which such an enormous pressure as 160 pounds should be exerted. If the after-coming head is retained by tonic retraction of the womb, such traction force must tear through the cervical tissues. If the head is retained by the brim of the pelvis, it is nearly certain that the child will be stillborn when the necessity for such an amount of force exists. It is a question whether we ever should use much force in pulling on the child? Whether, indeed, the head cannot better be shoved through the pelvis by suprapubic pressure, in the manner described by Dr. Goodell and Dr. Taylor.

There is one injury to the child which I do not think was particularly referred to by the author. He spoke of the dislocation of the occipital bone which sometimes occurs. In the case of a flattened pelvis, where the head enters in the transverse diameter, it will sometimes happen, where forceps are used, that the pressure of the blades bears directly upon the forehead and upon the occiput. This will be tolerated for a certain

length of time, but, when continued, the pressure ultimately affects the medulla oblongata. It is then difficult to get the child to breathe, the respiratory sense being destroyed, and often the child is born dead, as the result of such pressure. It is always well to be careful that, when the blades of the forceps cannot be applied to the sides of the head, they are applied in the oblique diameter.

With reference to fracture of the clavicle, it sometimes happens that this injury is due to direct pressure; more frequently, according to Ruge, it is due to the introduction of the hand into the vagina to bring down an extended arm. If the pelvis is small, the vagina rigid, and there is insufficient room for the hand, as the result of pressure upon the shoulder, the clavicle is apt to bend like a bow, and break in the middle.

In a well-conducted labor, the arms should not become extended above the head. In cases where this does take place, we know the directions that are given to draw on the elbow and push the arm over the face, but where the space is small you cannot always press the arm around the front of the face in the limited time required to extract the child alive. In these cases I think that we are justified in breaking the arm to accomplish delivery. Cases of true dislocation are probably exceedingly rare; at least we have no evidence of cases where the lesion has been demonstrated by dissection; but separation of the epiphysis closely resembles dislocation backward or forward, and, until dissections were made, dislocation was considered a common accident. There are one or two points in regard to separation of the epiphyses that are of interest. As a consequence of this fracture, Küstner has shown, that the cartilaginous portion of the bone is rotated outward by the action of the infra- and supra-spinatus and the teres minor muscles, while the shaft of the bone is rotated inward by the pectoral muscle, the latissimus dorsi, and the teres major. If the position of the arm is not rectified and union is allowed to take place, the movements of the arm will be more or less affected. Both external and internal rotation can then be accomplished only to a slight extent. Separation of the epiphyseal end of the humerus closely simulates paralysis, and some recent writers have gone so far as to assert that all cases of supposed paralysis of the arm are really cases of this injury. This is, however, not always the case. Last summer I attended an excitable primipara, who early in labor passed into a maniacal condition, which necessitated keeping her under an anæsthetic.

After the chloroform had been kept up for two or three hours, the cervix was partly dilated, and not wishing to continue the chloroform, for the immunity which attends its use in labor does not apply to its prolonged administration, I put on the forceps before dilatation was complete, and with considerable difficulty extracted the head through the cervix, the vagina, and through the vulva. The perineum did not tear, but the moment the head escaped, the vaginal orifice closed down tightly on the neck of the child, and I was compelled to introduce two fingers into each axilla to complete the delivery. After the birth one arm was found to be paralyzed. As I knew these have been recently asserted to be cases of epiphyseal separation, I examined the arm with great care, but failed to find the slightest evidence of fracture. There was no pain. There were no evidences of brain disturbance, although the pressure of the forceps had been continued for a long time. The galvanic current was applied to the arm, frictions were employed and it was kept warm, and in about ten weeks the child began to move its arm, though recovery is still far from complete.

To pass over the other points referred to, I should like to say a few words in regard to extraction in breech cases. It is nearly impossible where the arm has been bent behind the neck of the child to extract the arm without fracture. Then why not fracture the arm? Is the physician responsible if this accident occurs as the result of efforts to release the member? I should say, no, but he is responsible for the displacement of the arm behind the head. If he lets the body alone and does not twist the trunk, the arm will not remain extended. The child does not spontaneously flex its arm and place the forearm underneath the occiput.

There is a case recently reported by Englebach which I would add to the list of accidents. In this case the child was born with an enormous swelling of the scrotum, due to an effusion of blood into the tunica vaginalis of each side.

I have taken some interest in the questions connected with the extraction of the breech when both extremities were reflected upward, and I wish to reiterate what I said two or three years ago with reference to the use of forceps to the breech. In a recent brochure, Küstner condemns this method, but confesses to have never tried it. We all know that in the exercise of the usual method, a person with strong fingers is capable of exerting a great deal of force which bears to a great extent on the sacro-iliac synchondrosis,

and under these circumstances rupture of the sacro-iliac joint is likely to take place—a rupture which may be followed in after life by the development of the Nægeli deformity. I think that the application of the forceps to the breech is easier than a person who has not tried it would suppose. I speak of cases where the breech has reached the floor of the pelvis. Here it is not necessary to use a great deal of force. If the breech is brought down to the perineum and then allowed to recede, and this is continued until physiological softening of the pelvic floor and perineum takes place, a very moderate degree of force is required. I think that the use of the forceps under these circumstances is attended with less risk to the child than the employment of the finger or the blunt hook. I have succeeded with the forceps in three cases where the fingers had been used in vain.

I do not feel like occupying any more of the time of the Society. I would say, in conclusion, that this is a subject to which too much attention cannot be given, for woman after passing through the discomforts of the period of gestation, and the perils of labor, is entitled to the only reward that it is possible to give her, that of having a living child, sound in body and limb; and anything that will contribute toward the prevention of such a record as we have heard to-night is certainly worthy of the attention of any body of scientific men. At the present time the public hold us responsible if we allow a patient to die of puerperal fever. It would probably intensify our interest in the subject if the public were to take a similar position with reference to dead and injured children.

DR. E. WILSON said: I have been much interested in, and instructed by, the paper of the evening. I was glad to hear the last speaker condemn the use of great force in the delivery of the child by forceps, or by traction in cases of breech presentation. With reference to the application of the forceps to the breech, I can only say that I have participated in but one case where such application was made. This was a case of first labor, and the physician had applied the forceps to the breech on the supposition that it was the head. As the labor was progressing satisfactorily and safely, cautious traction was made with the forceps, and the labor terminated without injury to the mother or the child.

DR. H. LEAMAN said: I think that the presentation of this subject has been opportune. I believe that we are entering upon

a new period with reference to the subject of labor. The careful studies of gynecologists have forced upon obstetricians the careful use of instruments.

Some of the injuries referred to to-night I have seen. In my early practice I was unfortunate enough to fracture the inferior maxilla, but that has been the only case in a practice of twenty years. I have seen the clavicle broken, and I have seen paralysis. I recently had a case of facial paralysis, which was due to the fact that the sacrum was greatly curved, the coccyx being movable. The presentation was vertex left front, but the head was held from complete rotation by the deep curvature of the sacrum. This was overcome without difficulty by the application of the forceps. The instrument was then removed, and the labor allowed to proceed. The caput succedaneum was on the right parietal region, while the paralysis was on the left side. This passed off in the course of six weeks.

The injuries referred to are rare, and I believe have been necessary in the course of events. It is to be hoped that they may in great measure be prevented in the future. There is one injury not mentioned, which I am satisfied exists to a greater extent than any already referred to. I believe that too much haste in delivery, and in tying the cord, often causes non-closure of the foramen ovale. I have made a number of post-mortems in the case of children, and I have found the foramen ovale open too frequently. Many of the nutritive diseases of childhood are doubtless due to malnutrition resulting from a persistent foramen ovale.

DR. WHARTON SINKLER said: A very large proportion of the cases of paralysis, that I have met with in infants, have followed instrumental or prolonged and difficult labors. The most frequent form that we meet with is facial paralysis, either unilaterel or bilateral. This generally results from the pressure of the forceps upon the facial nerve or upon the mastoid process. Facial paralysis may, however, result simply from the impaction of the child's head in the pelvis without the use of the forceps.

Hemiplegias are often met with in the newly born as a result of the use of the forceps. A few days ago I saw a child with right hemiplegia, and the mother stated that the child had been delivered by forceps, and that immediately after birth there was a deep depression behind the left ear. I found upon examination of this child, who was now sixteen months old, that a depression still existed in the left mastoid process. There was

right hemiplegia present. The right leg was spastic and the movements of the arm limited and incoördinate. Spastic paralysis, and what is sometimes called double spastic hemiplegia, very frequently occur in children who have been born by the breech. These conditions generally persist during life and are associated with a feeble condition of the intellect.

Professor Parvin has referred to injuries to the sterno-cleido-mastoid muscle. I have seen cases where the child has lost power in all the muscles of the neck, so that it was unable to support the head. Some of the cases have been delivered by the breech and considerable traction made. Some have followed delivery by forceps, perhaps from pressure on the spinal accessory nerve, or perhaps from extravasation of blood. In the case of paralysis following difficult or instrumental labors, the lesion is often an extravasation of blood over the motor convolutions, a meningeal hemorrhage. If the amount of the extravasation is great, the prognosis is, of course, bad, but in some of the cases, especially where there is monoplegia, where there is paralysis of one arm alone, the child entirely recovers the use of the limb; and in facial paralysis recovery, as a rule, occurs in a few days, but the condition may persist during life.

DR. C. B. NANCREDE said: I believe the treatment of the injuries of the soft parts is too often left to the nurse, who either does nothing, or does that which ought not to be done. It has been recently shown that even the slightest injury of the scalp may end in periostitis, inflammation of the sinuses, meningitis, encephalitis, and often pyemia. The prompt carrying out of antiseptic precautions greatly reduces the mortality from such injuries. Although in these cases certain forms of antiseptic dressing may be impossible, the principle of antiseptis is easily carried out in many ways. Here, of course, the Lister dressing, or the application of any irritant or poisonous substance, is out of the question. But we may use boric acid freely, and it has the especial advantage of being a dry dressing.

Depression of portions of the bones of the skull, without fracture, is readily understood when we study the anatomy of the bones usually broken, viz., the parietal, frontal, occipital, and squamous plate of the temporal. Ossification proceeds from the centre in ray-like projections of bony fibre which, near the free edges of the bone, readily admit of various new relations to one another, without actual rupture of the osseous fibres.

I believe, however, that fractures are more common than is generally supposed; but that they are not noted, because the break is usually a simple fissure, or because it is concealed by a marked "caput" or cephalæmatoma, since such injuries are usually met with after hard or instrumental labors. I would call attention to the fact that simple fracture of the skull is in itself of no consequence. The injuries to be feared are those done at the same time to the subjacent tissues by the force which produces the fracture. If I should ever see a case in which I was convinced that existing paralysis was due to depression, I might trephine. The recently published statistics, that seem to indicate that trephining under antiseptic precautions is entirely without danger, are not to be relied on, and, while I am a thorough believer in antiseptics, I must call attention to the fact that as inflammation of the membranes or brain may occur from injury without any break of the cutaneous surface whatever, you certainly may have the same after, and because of trephining, despite antiseptics. Trephining cannot remove many of the conditions referred to by Dr. Sinkler, which are the real sources of danger, such as effusion of blood upon the surface of the brain or in the arachnoid. Fractures producing epileptic seizures, etc., later in life, are rough fractures where projecting spiculæ or rough edges impinge on the brain or membranes; and such fractures—except perhaps, *very rarely*, projecting rough edges—cannot occur in the infant skull; which is *devoid of* an internal table, from the shattering of which, in fractures in adults, secondary nerve trouble results. In the skull at birth, the articular eminence, which keeps a dislocated adult jaw from returning to its normal position, is practically absent; so that a dislocation of the jaw cannot be produced unless the force is sufficient to tear the soft tissues surrounding the articulation, giving rise to a compound dislocation. If the force applied is less than this, as soon as its application is suspended, the jaw returns to its normal position.

I believe that fracture of the long bones during labor is not very common, but that separation of their epiphyses is, for their union with the shaft is effected at this time only by the periosteum and soft cartilage. It has been shown that a few pounds weight exerting cross-strain will cause the separation, while six times the weight applied by direct traction will produce no injury. I do not believe that the injuries reported as dislocations were dislocations; but think they

were separations of the neighboring epiphyses or pathological displacements. Any one who is accustomed to dissect the body of the newborn child knows how readily such separations are produced. No one has ever been able to produce a luxation in an infant's cadaver, because of this ease of separation of the epiphyses. Dr. Lusk has described a case of separation of the upper epiphysis of the humerus, which produced a peculiar displacement. Probably in this case all the epiphyses of the proximal end were together separated from the shaft. I would advise in the reduction of a similar case, the method proposed by Dr. Moore, of Rochester. In the treatment of fractures of the foetal humerus, a friend of mine has had good success by fixing the whole upper extremity with a moulded splint in a straight position. Fractures of the femur are more difficult to manage. Here sheet vulcanite which can, by softening in hot water, be accurately moulded to the limb, had better be used, because it will absorb neither urine nor fæces. An anterior splint should be made which will extend well up over the abdomen, and a posterior splint to reach from the buttock well below the knee, thus fulfilling the important indication of fixing the joints above and below the fracture. It only requires ten or twelve days for firm union to occur.

In speaking of torticollis the sterno-cleido-mastoid muscle has alone been referred to. It is possible that in some cases this is the only muscle at fault, but in most instances several other muscles, as the trapezius and scaleni are involved. I have seen instances of injuries to this muscle in the newly born, but have never traced the cases in later life. Again, in a recently treated case of so-called congenital wry-neck, absolutely no history of injury during labor could be elicited.

DR. W. GOODELL said: I present for inspection this evening a specimen of firmly united fracture of an infant's humerus, of which I am not ashamed, but rather proud; for by the fracture I saved the child's life. It was a case of breech presentation, where the heart's action was failing and the ominous convulsive movements of the child were giving out, which indicates the near approach of death. The arm was up alongside the child's head, and if I had had more time, I could have brought it down without injury; but every second was precious. So I snapped the arm, and quickly delivered a living child. It died a few months afterward of cholera infantum, and the mother, knowing my interest in the case, allowed me to obtain the specimen. I have

reported elsewhere a unique case, where fracture was produced by the maternal forces. The vertex presented, the pains were strong, the passages ample; but the head did not descend. Suddenly, during a very severe pain, a hand shut out of the anus, without tearing the perineum. While I was gazing on in amazement, another pain suddenly took place. There was an audible snap, the hand as quickly disappeared from the anus, and the child was born with a fracture of the clavicle. The rent in the vagina was sewed up, and the fracture dressed with adhesive strips. The vaginal wound healed up perfectly, and the child recovered without deformity. This remarkable accident I attribute to the arm being thrown across the nucha. The protruding hand perforated the vagina, and was button-holed there. Then the advancing body forcibly dragged the arm down the back of the child, and the clavicle was fractured by the twist or strain it sustained.

In a case seen with my friend, Dr. James F. Wilson, fracture of the clavicle, and of the skull also, occurred. It was an exceedingly difficult case. She was delivered in her first labor by craniotomy, by Dr. Wilson, in conjunction with the late Dr. Parry. In this, her second labor, after using the forceps ineffectually, we turned, and delivered in a very few minutes, by vigorous traction and by very great pressure from above. The fractures were caused by the projection of the sacro-iliac promontory. The child recovered perfectly.

I have repeatedly seen facial paralysis; but in instrumental labors it has occurred only when the blades of the forceps were not applied exactly to the sides of the child's head. Dr. Parvin speaks of the child living a few hours after the performance of craniotomy. It was to such an occurrence that we owe the travels of Mungo Park, who was a physician, but who, early in his professional career, was so disgusted by this accident that he gave up practice. In his case the infant lived to manhood. With regard to head-last labors, I have tried to deliver the breech by the use of the forceps on the buttocks, and have succeeded with them, but they are liable to slip off. I therefore always bring a leg down in breech cases, and then I have command of the situation. The force of traction which the neck will bear is uncertain, and doubtless varies greatly; but I believe that the man who, in trying to save the child, breaks the most necks, saves the most children, and I respect him accordingly. Such labors are al-

ways very dangerous to the child; the percentage of deaths is a very large one. I look on a child in breech presentation as a child drowning, to which help must be sped—help at all hazards. It is emphatically a case of "neck or nothing," and we must not sacrifice the life of the child to any sentimental considerations about breaking its neck.

One point that perhaps does not come strictly under injuries to the foetus, but may be considered here, since it causes the death of the foetus, is pressure on the cord, prolapsed or wound round the neck, by one of the blades of the forceps, and especially by the occipital one, when the blades are not applied exactly to the sides of the head. I am sure this has occurred at my hands. An annoyance in cases of face presentation is the subsequent unnatural position of the child, which for days will lie with its head greatly extended, though it ultimately takes the natural position.

DR. D. LONGAKER said: I wish to speak of injuries to the soft parts of the head, from application of the forceps and pelvic deformities. I have reported a case where, after premature delivery with the Tarnier forceps, through a rachitic pelvis with a conjugate diameter of three inches, there was a rather clean-cut contused wound in the left anterior parietal region, which I am morally certain was not made by the extremities of the forceps, but occurred when the head suddenly slipped through the narrowed conjugate diameter. Then there are wounds caused by faulty construction of the forceps, particularly an excessive cephalic curve, which brings the distal extremity of the blades into close apposition. I have seen one cut, and several severe bruises, produced in this way. A peculiar parchment-like condition of the bones of the foetal head is sometimes observed, especially of the parietal bones; and I have seen it so marked that I was able to diagnose it through the abdominal walls, but have never known it to lead to fracture. Fracture of the long bones has only occurred in my experience where the difficulties to delivery of a living child have been insurmountable. I have seen one case of separation of the epiphyses of the humerus, in a very large child, which was dead when delivered; and I have had one fracture of the femur from the application of the fillet, this being also a difficult delivery of a dead child. I fully agree with Dr. Leaman as to the injury of tying the cord too soon. The researches of Budin have fully shown this. I think we ought to lay

down the definite rule, that the cord should never be tied until flabby, pale and pulseless. It has happened to me also to compress a loop of the cord in the application of the forceps. I am glad to learn that Dr. Goodell succeeds in converting face into vertex presentations, by introduction of the hand; but if we fail in this we have produced an early rupture of the membranes with all its undesirable effects. For this reason the method of Schatz, of Rostock, is to be preferred.

DR. H. C. WOOD said: It has been eleven years since I attended a case of obstetrics, for which I trust I am duly thankful; and I should not presume to take part in this discussion had not the remarks of the last speaker been so entirely contrary to my own experience. We do not see hemiplegias and paraplegias due to injury during labor, in children of five or six years, simply because children so injured never live that long. What we do see are the cases of spastic paralysis. Spastic paralysis is the secondary effect of an earlier destructive lesion, the immediate evidence of which may have been entirely overlooked. In all such cases presenting at my clinic I inquire as to the history of the labor; and invariably find that it has been unusually severe or instrumental. The brain at birth is so soft, so liable to injury, that while I would not have the obstetrician entirely discard the use of the forceps, I think he should never take them in his hand without bearing in mind the possibility that they may do serious permanent injury to the nerve centres of the child.

DR. W. H. PARISH said: Though Dr. Wood is no obstetrician, he talks like a very sensible one. I believe the forceps in proper hands save the lives of many children; but where improperly used they sacrifice not infrequently the child's life and often lead to subsequent harm. Their application at the superior strait is, under some conditions, exceedingly dangerous to the child.

Last year I saw a laceration of the child's perineum, extending from the vulvar orifice clear through to the rectum, produced evidently by the tip of one blade of the forceps, which the practitioner had attempted to apply to an unrecognized breech presentation.

I recall the case of a robust Irish woman at the Blockley Hospital, who had borne five or six healthy children. Labor was delayed, and ergot was freely and, of course, improperly given in my absence, until the contractions came on with unusual force. The child was speedily delivered, but died in a few minutes. At the autopsy I found that the

principal lesion was a separation of the lateral, or articular, segment of the occipital bone, which was pressed in upon the medulla; doubtless by the excessive contractions produced by ergot. Recently, a friend of mine saw in consultation a child, which, having presented by the breech and the scrotum become considerably distended from oedema; the medical attendant, mistaking the scrotum for the bag of waters, had cut it open and cut into the testicle.

DR. J. PRICE said: I desire to call attention to the fact that the "Simpson forceps" probably makes less compression of the head than any other form in use. As to the frequency of separation of the head and trunk, by contraction in head-last labors, I might say that I knew of two cases in which it has occurred this summer, in this city. In one the patient died after Cæsarean section for the removal of the head; and the other died and was buried with the head still in the cavity of the uterus.

DR. J. L. LUDLOW said: When I was a student, Dr. Hodge taught us to apply the forceps only after careful deliberation and consultation. Since then the forceps have come into more general use; and there are certain practitioners, who, if labor does not terminate in a certain set time, will always apply them, and who thus get a reputation for quick delivery, and draw patients. The obstetrician needs a great deal of patience, and great injury is often done by want of it.

DR. PARVIN, in closing the discussion, said: The reason obstetric paraplegia is not seen at six or seven years is that such paraplegia is caused by rupture of the spinal cord connected with fracture of some portion of the vertebral column, and death follows very quickly, usually within a very few hours.

As to the treatment of fractures of the femur in the newborn, I regret that a gentleman present did not narrate a case of such injury to which several practitioners were called. Their first effort was to extend the limb completely, in order to treat the fracture somewhat after the manner of treatment in the adult; but finding their efforts vain, it suddenly flashed upon the minds of the surgeons and obstetricians that an infant did not have its lower limbs extended, and they resorted to a more rational method of keeping the ends of the broken bone in contact, and it was completely successful.

I am not prepared to admit that dislocations of the humerus or femur cannot occur in labor, because reputable observers claim to have seen them, though, of course, they are quite rare.

I cannot help regretting that some time has not been given to the discussion of what is the best method of delivery of the head, especially in pelvic presentation, or after podalic version. Is there not a better way to bring the head through a narrowed pelvic inlet than the great traction upon the body which has been recommended? It seems to

be impossible to make that traction directly in the axis of the inlet, and hence much of it is lost, and therefore useless or injurious, force.

Finally, the relation between protracted labor and forceps' delivery, and remote disorders of the nervous system, and especially with idiocy, probably has not elicited that consideration its importance demands.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Treatment of Sea-Sickness.

Dr. W. W. Skinner, who says that he has investigated sea-sickness in the course of several long voyages in 1886, as ship's surgeon, recommends the following treatment as at once simple and efficacious:

The medicinal substances employed are atropine, strychnine and caffeine; the two former are administered simultaneously, the latter alone. Sea-sickness may be cured either by atropine associated with strychnine or by caffeine held in concentrated solution by salicylate or benzoate of sodium. These substances are all administered hypodermically. This mode of administration was chosen for the following reasons: The frequent vomiting in naupathia, by which the agents employed would be lost; the difficulty of their absorption from the stomach in this affection; and also the retaining and destructive action of the liver upon these alkaloids when absorbed from the gastrointestinal tract (Heger, Schiff, Lautenbach, and others).

The dose of atropine and strychnine for adults is 1-60 grain of each. It would, perhaps, be better to give a little less of atropine and the double or triple of strychnine. In warm climates the solution must be frequently renewed. Although these substances have been employed a great many times for sea-sickness during the last eighteen months, no injurious effect therefrom has been observed. If after two hours the patient is not cured, a second injection may be given, but it would be imprudent to repeat this dose of atropine too frequently.

Children and adolescents are very susceptible to this medication. A girl, aged $2\frac{1}{2}$, sick during fourteen hours, was promptly cured by the injection of one-sixth of a gramme of the solution, that is, by about $\frac{1}{160}$ of a grain of atropine and as much of strychnine. A boy, aged 6, was cured by $\frac{1}{160}$ of a grain of each.

In the majority of cases of simple naupathia, the patients cease vomiting immediately after receiving a single injection. A little later they feel no more nausea, headache, nor vertigo. Almost always they fall asleep shortly after receiving the injection, and remain sleeping for half or three-quarters of an hour. If given late in the evening, the injection ensures a refreshing night's rest.

The following is the formula employed in administering caffeine to adults: Caffeine, gr. lx; sodii salicyl., gr. xlv; aq. destill., q. s. ad., f3iii. Dissolve by gentle heating. Every 20 minims contains about 6 grains of caffeine. A single hypodermic injection of four grains of caffeine completely cured in seven hours a patient who had been suffering intensely from sea-sickness during three days. Another patient was cured in five hours.

Certain disadvantages of the method exist, but are not of great importance. Dryness of the throat is sometimes caused by the atropine, and young children may present an intense redness of the skin; amblyopia caused by this alkaloid is occasionally observed in adults. Exceptionally, the seat of the injection remains somewhat painful, especially in lean individuals; and once in my experience troublesome inflammatory symptoms were caused by an injection under the skin of the outer border of the forearm, which, however, spontaneously subsided in the course of two days.

If this method produces no favorable effect upon a given person affected with naupathia who has not exceeded the age of adult life, it is almost certain that the failure is due to an organic lesion in some part of the circulatory apparatus, especially in the valves of the heart. For example, a patient having well marked mitral insufficiency received in the space of six hours three injections, each containing 1-60 of a grain of atropine and 1-60 of a grain of strychnine, without the slightest favorable result, the

only change in the symptoms being an increase in the number (but not in the force) of the cardiac pulsations. It is well to remark that, if these injections produced no amelioration in this case, they did not, on the other hand, occasion any aggravation.

The two alkaloids exhibited in the form of pills, however, have successfully warded off sea-sickness, when taken immediately upon feeling the first approaches of nausea.

The Frequency of Malignant Tumors of the Ovary and their Treatment.

Prof. Leopold, of Dresden, in an article in the *Deutsche med. Wochens.*, November 4, 1887, says that he has removed twenty-six malignant tumors of the ovary in one hundred and sixteen ovariectomies, and therefore in 22.6 per cent. of all the cases. This percentage exceeds somewhat that obtained by Cohen from Schroeder's material. According to Cohen's statistics, Schroeder had, in six hundred ovariectomies, operated one hundred times for malignant tumors, or in 16.6 per cent. of the cases.

Leopold's twenty-six cases of malignant tumor of the ovary were divided as follows: Papillary cysts, 5 (three monolateral, two bilateral); carcinomatous cysts, 11 (six monolateral, five bilateral); solid sarcomas, 4 (two monolateral, two bilateral); the remaining six cases were those in which a preliminary incision showed that a radical operation was impossible. Of his 110 complete ovariectomies, four died of septic infection (3.6 per cent.); of the 26 cases of malignant tumor, five died as a result of the operation (19.1 per cent.). Of the 20 cases in which a radical operation was still possible, four died as a result of the operation (20 per cent.).

Of the 16 remaining cases, three are to be excluded because they are of too recent a date to enable one to say positively whether they are cured or not. Of the remaining thirteen which have been operated on above a year, nine have had relapses within from a month to a year; four, on the other hand, are, up to the present time, regarded as cured. Therefore, 20 per cent. of all cases operated on for malignant tumor of the ovary, have been entirely well for over a year. This result entirely agrees with Schroeder's.

Leopold concludes that the sooner the diagnosis is made and the ovaries removed, the better will be the prognosis. He also thinks that the smaller tumors of the ovaries are to be removed as soon as they begin to enlarge; especially if they are bilateral.

Every proliferating tumor of the ovary is to be removed immediately.—*Deutsche medizinisch-Zeitung*, September 29, 1887.

Acute Rheumatic Peritonitis.

Dr. William Robinson contributes the following instance of this rare affection to the *British Medical Journal*, Oct. 15, 1887:

M. E. G., 17 years old, tall, slender, and a twin, was seized with severe abdominal pain and vomiting on January 3d, 1887. On January 15th, Dr. Robinson was called to see her, when he found her in bed, lying on her back, with knees drawn up; severe pain in her abdomen, increased by pressure, and excessive tenderness, especially of the hypogastric region; pulse, 110, weak; temperature, 99.4° F.,—in fact, all the symptoms of acute peritonitis. A normal menstruation had ceased five days before the attack; there were no signs of renal or pelvic disease; and the only history bearing on the case was that the patient had, two days before the attack, walked two miles in the severely cold night air. The usual instructions as to diet, rest in bed, external applications, and avoidance of aperients (which had been given by her mother at the onset) were given, and a mixture, containing opium, prescribed. During the first week the pain was kept in subjection by the opium, but the pulse remained frequent, the temperature rose to 102°-103°, and the inflammation extended to the whole of the peritoneum. The tongue was dry, red, small and characteristic, and the breathing altogether costal. At the end of the first week severe pain paralyzed the right knee, which became very tender, but not red or swollen; the temperature rose to 104°, signs of pericarditis developed, and sour smelling acid sweats set in. After two days the right knee became free from pain, but the left shoulder was attacked with acute pain, but without redness or swelling. In a few days more the left elbow followed suit. As the pericarditis developed, the abdominal symptoms subsided gradually, but dulness, loss of voice resonance and breath sounds became marked at the bases of both lungs (double pleurisy with effusion). The respirations were short, and 34 per minute. At the end of the second week the heart dulness had greatly increased, and extended from one-half an inch to the right of the sternum to half an inch to the left of the nipple, where the heart impulse was felt (on a level with the nipple); in the second left intercostal space a well-marked friction fre-

mitus and sound were preceptible during the whole time the pericarditis lasted, and here also an easily seen wave-like motion was visible, due to and synchronous with each cardiac systole (that this wave-like movement was not due to fluid effusion was clearly proved by the friction sound being audible only over the same area). On endeavoring one day to examine more in detail the back of the chest, the patient was quietly raised a little from the previously carefully maintained dorsal position, when hiccoughing, "catching of the breath," and fatal syncope almost occurred, and was only warded off by the speedy restoration to her former position, and by stimulants. From this time up to the fifth week gradual improvement took place; the patient was able to sit up in bed; the abdominal tenderness, tympanites, and increased heart dulness had almost gone, and the temperature and pulse had become normal, when, presumably from a slight error in diet, a relapse of the peritonitis occurred, and the pain returned for a time to her left shoulder; but she again gradually recovered, and by the third week in March she could take an ordinary diet with impunity, walk out of doors, and had no shortness of breath. The heart dulness and apex beat were almost normal, but a systolic *bruit* remained. In April she was continuing to regain flesh and strength.

There can be little doubt but that this case was one of acute rheumatism, in which the visceral affections eclipsed those of the joints. The only other view that could be advanced is that the peritonitis was "idiopathic," and that the pleuræ and pericardium were affected through the lymph channels existing between those serous membranes and the diaphragm. There were never any signs of typhoid fever, and tubercle was out of the question. Paracentesis pericardii was not performed, because (1) the symptoms were never sufficiently alarming, (2) the effusion was regarded as rheumatic, and (3) the fluid gradually became absorbed.

Hypertrophic Cirrhosis of the Liver Cured by Calomel.

Dr. Schnepf, of Vienna, states in the *Wien. med. Blätt.*, No. 14, 1887, that he had as a patient a woman, twenty-eight years old, who presented marked symptoms of cirrhosis of the liver. The liver, as demonstrated by percussion, was considerably enlarged. After a sojourn of five weeks at Carlsbad had resulted in no benefit, and brisk purgatives followed by opiates had

effected only a slight improvement, at the suggestion of Prof. Nothnagel, the patient was put upon an absolute milk diet, and given calomel three times daily, in doses of $\frac{3}{4}$ of a grain. On the second day the fæces became yellowish, and the urine clear. After some weeks jaundice and acites disappeared, the liver became smaller and the menses reappeared. At the end of three months the patient had taken one hundred doses of calomel and was completely cured. Pain, enlargement of the liver, ascites, caput medusæ, were no longer present.—*Deutsche Medizinal-Zeitung*, September 29, 1887.

Treatment of Chronic Constipation by Electricity.

Leubuscher (*Centralblatt f. klin. Med.*, 1887, No. 25) has found electrical treatment useful in chronic constipation connected with nervous disturbances, chronic cerebral and spinal diseases, and in cases in which the fæces were hard and dry. Hitherto the faradaic current has been for the most part used in constipation, but Leubuscher finds the galvanic current more efficacious. He passes an electrode connected with the cathode into the rectum, and applies the anode to the abdominal walls in the course of the large intestine. He does not mention the number of cells he employs, but says he used a current which, without causing pain, could be distinctly felt. Each application lasted 10–15 minutes. Although Leubuscher claims that his treatment is successful, his statistics seem only to indicate that galvanic treatment may at times be used with advantage when other means have failed. Out of fifteen cases four were cured, in nine constipation was temporarily relieved, but returned shortly after the electrical treatment ceased, and in two no good results followed. The treatment should be carried out for three to five weeks daily. The first three or four applications are generally without apparent effect, and for some time the action of the bowels does not occur from five to twenty hours after the galvanic current has been employed, but gradually the interval is reduced to two or three hours, and the fæces become softer. Where constipation is connected with abnormal weakness of the abdominal walls or atrophy of the intestinal muscles, Leubuscher recommends massage; and he advises this method of treatment, too, in the constipation sometimes present in chronic heart and lung diseases, and after prolonged intestinal catarrh.—*Med. Chronicle*, September, 1887.

Intrauterine Fractures of the Tibia.

Heinrich Braun (*Arch. f. klin. Chir.*, xxxiv., S. 668) has carefully collected together twenty-seven cases in point, four of which he observed himself. He calls attention to the fact that as a rule these fractures occur in healthy individuals without other malformations, and that the lesion of the tibia actually occurs in the uterus through a break, or at least an infraction. To be sure, the injury is not always due to a force acting upon the body of the mother, but probably also arises through pressure of the uterus upon the yielding limbs of the foetus. Possibly in the latter cases there exists an association of the fracture with a defective development of the fibula, which lessens the resistance of the lower part of the thigh. These defects are of themselves rare; but in twenty-seven cases of congenital fracture of the tibia they were noticed sixteen times. A very frequent result of intrauterine fracture is shortening of the affected limb, which is not to be explained by fracture of the lower part of the thigh, or by previous ossification of the epiphyses, but must depend upon disturbances in the longitudinal growth of the tibia. The number of cases in which the retardation of the growth of the affected lower extremity could be followed up to a somewhat later period of life is, however, very small. As regards treatment, a greater interference than would be represented by a Keil osteotomy or by an osteoclast, is only indicated in marked angularity of the tibia. In very moveable ankle joints, in which the foot is constantly rotated outwards, Braun has obtained artificial ankylosis of the ankle-joint in the position of equinus.—*Centralblatt f. d. med. Wissensch.*, August 27, 1887.

A Cause of Left-Handedness.

Dr. Feltz, of Saint-Denis, reports in *La France Médicale* the following observation, which seemed to him sufficiently trustworthy to put in evidence as one of the most frequent causes of left-handedness:

In a family composed of five persons, the father and mother are not left-handed, nor is the eldest of the children, who was raised by a nurse. The second child has been left-handed from its earliest years, and remains so; it is now five years old. The third child has been left-handed since it was a year old, when it was offered something and at once grasped it with the left hand. The mother herself had nursed the last two children, and was in the habit of carrying the child upon

her left arm. This she has done with both children who were left-handed. She was admonished to carry the child upon the right arm, and some months afterwards the child was found to have lost the habit of using its left hand, and became as right-handed as the eldest child.

Feltz explains this case by the fact that when a child is carried upon the left arm, it is also the left arm of the child that is in front of it, and is free to move and grasp objects; on the contrary, when the child is carried upon the right arm of the nurse, the right arm of the child is free to move. He adds, that in the families of the father and mother, and in the families of the grandparents, there are no left-handed people; and that in the second child, who continues left-handed, there are no blemishes, but it is perfectly well in all respects.—*Concours Médical*, September 24, 1887.

The Pneumococcus as a Cause of Meningitis.

Netter (*La Semaine Méd.*, No. 37, 1887), as the result of a number of observations, came to the conclusion that the pneumococcus may be the cause of simple meningitis, without a previous pneumonia; and that it may be the occasion of cerebro-spinal meningitis.—*Allg. med. Central-Zeitung*, Sept. 10, 1887.

Pilocarpine in Puerperal Convulsions.

Dr. Kirk (*Lancet*, August 13th, 1887), records two cases of puerperal convulsions treated by pilocarpine. The first was not of unusual severity. One-third of a grain of pilocarpine was injected and acted freely on the skin, but the patient died the same day after the birth of the child. The second case was complicated with purpura. One-third of a grain of pilocarpine was injected about half an hour previous to the expulsion of the child. Copious perspirations were produced, and the convulsions soon ceased. Dr. Kirk points out that the second case is no proof of the efficacy of pilocarpine, but the first is an instance of the failure of the drug in a case apparently well adapted for its use.—*Med. Chronicle*, Sept., 1887.

The Control of Hemorrhage.

Von Nussbaum finds peroxide of hydrogen of great value in controlling hemorrhage from the parenchyma of various organs, as well as from comparatively inaccessible vessels. The application is made with a pledget of cotton soaked in the peroxide.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	- 2.50
Reporter and Compendium,	- 6.00
Physician's Daily Pocket Record,	- 1.50
Reporter and Pocket Record,	- 6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

INTERMARRIAGE OF THE DEAF.

Not long since, Prof. Graham Bells suggested that a law should be passed forbidding intermarriage among the deaf. The object of such a suggestion is, of course, to draw attention to the danger of multiplying the victims of a very sad affliction, by direct propagation. This object is a very commendable one; and yet it conflicts with the personal interest of the deaf already. It is not surprising, therefore, that Mr. Hiram Phelps Arms has followed it by a published protest, in which he argues that the deaf should not be forbidden to marry the deaf, because marriage with those who can hear is apt to lead to unhappiness. He contends that those who can hear will not marry the deaf, except for reasons which do not justify marriage at all. These reasons are such as a desire to acquire property, or greater or less timidity or effeminacy

on the part of the one who hears—if it be a man; and age, widowhood or the blight of divorce—if it be a woman. He states that at present from eighty to ninety-five per cent. of marriages among the deaf are intermarriages.

In a discussion of this sort there is much more involved than the personal wishes of the class under discussion. These deserve consideration; but the good of the community is of greater importance. And, if it could be shown that the children of deaf-mutes are often afflicted like their parents, and that the spread of this affliction is dangerous to the welfare of the community; then, there could be little doubt of the wisdom of considering some plan for restricting it. But, even the need of interference would not be one-thousandth part as urgent as it now is for the prevention of intermarriage among those with consumption, or scrofulous tendencies, or of extremely nervous disposition, or of drinking proclivities. What danger threatens from a few quiet, gentle, orderly, if voiceless, individuals, compared with that which advances unchallenged in a multitude of cachetic wretches, who love and marry—or marry without love—unwarned by those who know the bitter consequences which may befall them, or be entailed upon their unoffending offspring?

For the present then we would say: let the deaf marry as they will; and only when more dangerous classes have been attended to will we disturb them in their innocent retirement.

THE RESULT OF OPERATION FOR CANCER OF THE BREAST.

HILDEBRAND, *Deutsche Zeitschrift für Chirurgie*, Bd. xxv., gives some interesting statistics upon the results of removal of the breast for cancer, in the Göttingen clinic from 1875 to 1885. The whole number of cases operated upon was 152. In 137 the axilla was also cleaned out, often when no implication of the axillary glands was apparent; 11 times the breast alone was removed; and 4 times only the tumor was excised. The deaths from the operation numbered

11, that is, 7.2 per cent. The cause of death was either septicæmia, or pneumonia. From the latter cause 6 patients died.

As to the result: in 135 cases in which a radical operation was performed, recurrence took place 65 times—half of them within six months. Of the 135 cases, 23 were free from recurrence for at least three years; 30 for at least two years; and 53 for at least a year. Hildebrand calculates the absolute cures as about 33 per cent., and emphasizes the importance of early and thorough operation, upon which so much stress has been laid by Prof. S. W. Gross, of this city. An interesting feature of Hildebrand's study relates to the age and condition of the patients. He found the age of greatest frequency of cancer of the breast to be from the 45th to the 55th year; and that nearly 90 per cent. of the patients were married.

HEMORRHAGE FROM VARICOSE VEINS OF THE LABIUM IN PREGNANCY.

A rare but perplexing accident, which may happen during pregnancy or about the time of delivery, is the rupture of varicose veins of the genitals. A case of this sort occurred in Paris last July, and is described by Dr. T. LEGRY, in the *Progrès Médical*, October 22, 1887. The patient was a woman who, near the time of her confinement, inadvertently sat down upon the iron rail which separated two seats on the top of an omnibus. She soon felt that she was losing some fluid, but paid little attention to it until she began to be faint, and her neighbors noticed a pool of blood collecting at her feet. After some delay, she was removed, in an exsanguinated condition, to the Hôpital de la Charité, where she came under the care of Dr. Budin. The hemorrhage had now ceased; but the woman was almost dead. On careful examination, it was found that the bleeding had proceeded from a ruptured varicose vein in the left labium minus. Under appropriate treatment—restoratives and a compressing bandage—the woman revived, and passed safely through her confinement the next day.

This case illustrates the fact that a very grave hemorrhage may follow an accident to

an unrecognized varix. Legry mentions thirteen such occurrences, in nine of which the hemorrhage proved fatal. Such a hemorrhage is apt to be very rapid and very profuse. More than this, its cause is apt to be misunderstood. In most cases it is attributed to placenta previa, in which case the application of a tampon may happen to cause efficient compression upon the bleeding point, or it may not. In the latter case, or when the examiner, finding no physical evidence of placenta previa, and overlooking the real source of the bleeding, waits for clearer knowledge, the hemorrhage may go on until it brings about the death of the patient. Legry very properly suggests that the practical lesson to be learned from these facts is that, whenever a pregnant woman has a sudden and free hemorrhage, there should be no hesitation in making a thorough examination of the external genitals. Such an examination would lead to the discovery of the source of the hemorrhage in case it was a ruptured vein, and then the treatment would be simple and easy—the application of compressing forceps, or a suitable tampon, or even simple digital compression until the bleeding point was sealed with a clot.

THE MICROSCOPE IN MEDICINE.

The editor of the *American Monthly Microscopical Journal*, August, 1887, speaks of the importance of the microscope in the study of medicine, and urges the cultivation of microscopy in medical schools. As an illustration of the ignorance of what can be done with the microscope, he says:

"We were shocked one day not a year ago to receive a visit from a practitioner in a certain city. He showed us a small tumor on his left hand, and asked to have it viewed with a microscope to see if it were malignant. We expostulated against such defiance of the rules of procedure, but promised to examine it if it were removed and sent to our laboratory. It was accordingly removed, and, after several days, fell into our hands wrapped like a piece of meat from the butch-

er's. This same gentleman told us he had but little faith in the diagnosis of disease by the aid of the microscope."

This is, as Dr. Osborn admits, an extreme case; and yet there is no denying the fact that many medical men are much less familiar with microscopical work than they ought to be. In no regard is this state of affairs more to be regretted than in the matter of the diagnosis of affections of the kidneys. The usual method of examining the urine only for albumin and sugar is too incomplete for the status of medical science in these days. If a physician has no microscope, or cannot use one, he will miss many a case of kidney-disease, which he would detect if he were better provided or better informed. No doubt a man may be a very successful practitioner without using a microscope; but no doubt, also, he would be a better physician if he did use one. To do this, does not require the expenditure of much money, or any prolonged course of study; and it would be a decided gain in the direction of scientific precision if more medical men would buy an instrument of moderate cost, and use it frequently. Of course, the best way to learn to use the microscope is to have the help of a competent teacher; but all that is essential for ordinary practice can be learned from books; and any one, who will try it, will be astonished to find what he can accomplish in a little while in this fascinating and useful study.

EPILEPSY AND NYSTAGMUS.

At a meeting of the Société de Biologie, of Paris, held October 15, 1887, M. Charles Féré called attention to the frequency with which epileptics suffer with nystagmus, and mentioned a case in which the nystagmus was subject to marked exacerbations, and accompanied with well-marked sensations of vertigo. This fact recalls the observations of Dr. Stevens, in his book on "Functional Nervous Diseases," which we reviewed in the *REPORTER*, November 5, 1887, page 622, and in which so many nervous disorders—among them epilepsy—are associated with disorders of the eyes.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the *REPORTER*.]

A MANUAL OF ORGANIC MATERIA MEDICA. By JOHN M. MAISCH, Phar. D., Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy. Third edition, with 250 illustrations. 8vo, pp. xvi, 532. Philadelphia: Lea Brothers & Co., 1887. Price, \$5.00.

This work has already met with so much favor that there is little to do, in noting the appearance of this third edition, besides saying that it is what one would expect from its talented author. The arrangement of the subjects is not alphabetical, but systematic, according to classes. The origin, habitat, description, constituents and properties of each drug are given in a clear and very succinct manner; and the whole book is full of valuable information. The work of the publishers is as creditable as that of the author; the paper, printing and binding being of the highest order of excellence; while the illustrations are superb.

DISEASES OF THE HEART. By DUJARDIN-BEAUMETZ, M.D., translated by E. P. HURD. Two volumes, paper. Square 16mo, pp. x, 316. Detroit: Geo. S. Davis, 1887. (The Physicians' Leisure Library, Nos. 2 and 4). Price, 25 cents each volume.

These two volumes constitute the most important parts of the series which Mr. Davis has been publishing this year at the cheap rate of twenty-five cents for each volume, appearing monthly. Those which we have already seen are two practical essays: one on the "Diagnosis and Treatment of Hæmorrhoids," by Dr. Kelsey, of New York, and one on "The Modern Treatment of Diarrhœa and Dysentery," by Dr. Palmer, of the University of Michigan.

The volume before us contains the teachings of one of the most eminent French clinical teachers of the present day, some of which have already been published in the columns of the *REPORTER*. They have been well translated by Dr. Hurd, who is a personal friend of the author. When the first volume of this series appeared, we felt that it was a serious drawback to their usefulness that they were printed in a color exceedingly trying to eyes not yet enfeebled by age. The second volume of Dujardin-Beaumetz's work, we are glad to say, appears in black, and is not open to this objection. The scientific merit of this work is very great, and it cannot fail to prove of value to careful students of the subject of which it treats.

NASAL POLYPUS, WITH NEURALGIA, HAY-FEVER AND ASTHMA IN RELATION TO ETHMOIDITIS. By EDWARD WOAKES, M.D., Lond, Senior Aural Surgeon and Lecturer on Diseases of the Ear at the London Hospital. Small 8vo, pp. xii, 140. Philadelphia: P. Blakiston, Son & Co., 1887. Price, \$1.25.

There is much food for thought in this brochure of Dr. Woakes, who has made a most thorough study of the subject of diseases of the ear, throat and nose, and who announces the opinion that nasal polypus, and other disturbances named in the title of his book, are dependent upon an inflammatory process in the ethmoid bone. He does not claim originality for this discovery; for he gives due credit to other workers who have arrived at analogous, if not identical, conclusions. But Dr. Woakes goes further than

any author with whose writings we are acquainted in attributing various local and reflex disturbances to an inflammation of the ethmoid bone, which he describes as first hypertrophic, and afterwards necrotic. The result of his studies leads him to the conviction that the proper treatment of these disorders is surgical: a conviction which seems to be pretty general now-a-days among students of nasal diseases.

We heartily commend this book to the notice of our readers. Its matter is good; its manner is interesting; and its mechanical execution is admirable.

TRANSACTIONS OF THE BROOKLYN PATHOLOGICAL SOCIETY. SESSION OF 1885-6. Large 8vo, pp. 233. New York: D. Appleton & Co., 1887. Edited by A. H. P. LEUF, M.D.

This handsomely printed volume of transactions indicates that the Brooklyn Pathological Society is a live organization; and the report of its transactions is both interesting and instructive reading, comprising not only descriptions of pathological specimens, and remarks suggested by them, but also elaborate papers upon subjects of general medical and surgical interest. One of the most interesting among these, is a paper by Dr. Robert G. Eccles, of Brooklyn, on "Some Serious Sources of Error in Studying the Course of Disease." In this paper, the author discusses the dangers which arise from the fact that medicines prescribed are so often different in character, or in strength, from what the physician expects. Druggists' errors, and even druggists' dishonesty, augment the variations which depend upon the want of acquaintance of physicians with the exact official strength of many drugs—especially since the adoption of the last Pharmacopœia.

The editor contributes an interesting paper on "Surgical Infection and Antiseptics," in which he combats the prevailing belief in germicides.

If we were to criticise these excellent transactions, it would be in saying that we think some of the papers would have been much improved by being more condensed. In fact, we wonder at what hour this energetic Society could have adjourned some of its meetings!

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The first number of the *American Journal of Psychology* has just reached us. It is a handsomely printed and illustrated octavo of 206 pages, edited by G. Stanley Hall, Professor of Psychology and Pedagogics in the Johns Hopkins University, and published by N. Murray, of Baltimore, Md. The numbers are to appear quarterly. The first contains a prospectus in which the object of the *Journal* is stated to be to bring together the contributions of various departments of science bearing on psychology, which are now scattered; and gives promise of great usefulness. The price is to be \$3.00 a year; \$1.00 a number.

—The November number of *The Cosmopolitan* contains an interesting and rather remarkable article by Julian Hawthorne on "The Noble Art of Self-Defence," illustrated by M. J. Burns, which is likely

to attract attention, because of its advocacy of pugilism and the author's personal reminiscences of Heenan and Sayers.

—The Committee on Publication of the Franklin Institute has in contemplation the publication of a general index of authors and subject matter to the first 110 volumes of the proceedings of the Institute, from 1826 to 1880, provided they can procure a sufficient number of subscribers.

—Dr. L. H. C. writes: "THE REPORTER contains notice of a work by Heather Bigg, on "Artificial Limbs and the Amputations which afford the most appropriate Stumps," but fails to give the price of the work. I would like very much to have it, if not too expensive."

[We did not give the price, because we are not informed what it is. The book can probably be obtained by applying, with our notice, to any first-class book-seller. We think it would cost about \$2.00.—EDS. REPORTER.]

—A subscriber writes, offering to buy of us certain books, if we will allow a discount on the published prices.

[We offer to oblige any of our subscribers by purchasing and forwarding to them any book noticed in our columns on receipt of the published price. This is intended purely as a convenience to our subscribers. We have no idea of entering into competition with regular book dealers; and if any subscriber can get a book from them for less than the published price, we advise him to deal with them directly.—EDS. REPORTER.]

CORRESPONDENCE.

Nitrate of Potash as an Anti-Emetic.

EDS. MED. AND SURG. REPORTER:

Sirs:—I wish to call the attention of the profession to the value of nitrate of potash as a remedy for vomiting.

Nitrate of potash, properly administered, is one of the surest remedies we have for the relief of vomiting. I have been using it as an anti-emetic in my practice, for the past twelve years, with the happiest results. I have made known its value in this respect to a number of my medical brethren, and they have each expressed themselves as pleased and surprised at its power in allaying nausea and checking vomiting. The manner of administering it is as follows: Give one-quarter of a grain, dissolved in a tablespoonful of cold water, every four or five minutes until the vomiting is relieved; which will usually be in from ten minutes to half an hour. I give it in all cases of vomiting, except reflex; and that due to irritant poisons, and have found it succeed in ninety per cent. of my cases. Try it; you will be surprised and pleased. It is pleasant to take, rendering it more valuable in nausea and vomiting in children.

Yours truly, V. H. MOORE, M.D.,
Brockville, Ont., Nov. 1, 1887.

Antipyrine.

EDS. MED. AND SURG. REPORTER :

Sirs.—Antipyrine of late is becoming quite popular as an antipyretic, and a great many of our best physicians are using it to control high temperature, in preference to sulphate of quinine.

I have profited by reading the article of Prof. Germain Sée, published in the REPORTER, Oct. 8th, upon the use of antipyrine in painful affections of the head. I have used antipyrine in reducing and controlling temperature, which it does effectually and promptly, and have had some satisfactory results from its use in the treatment of migraine. But I would employ it with more satisfaction to myself if I knew what I was prescribing. I understand that antipyrine is a patent medicine, and I have not been able to ascertain what it is. I beg leave, therefore, to ask you kindly, of what is antipyrine composed? And when, if there is a patent on it, will that patent run out?

Fraternally yours, W. G. HOPKINS.

Fort Branch, Ind., Oct. 29, 1887.

[In reply to these questions, we would say that antipyrine is a complex chemical body derived from chinoline, and called in chemical terms: *Dimethyloxyguinizine*. The name of antipyrine was applied to it by the manufacturers for two reasons: first, as a convenient term which would indicate one of its most important properties; and, second, in order to have a name which they could copyright, to protect their interests. The "patent" referred to by our correspondent covers only the use of the name "antipyrine." The chemical substance may be made by any one who can.—EDS. REPORTER.]

—In the *Bulletin Général de Thérap.* Dr. Béranger-Féraud reports a remarkable case. A man twenty-six years old had received a stab-wound in the *left* temple some nine months before presenting himself at the hospital. He was sent to the hospital by some physician who had diagnosed the case as one of lachrymal tumor of the *right* side. Examination in this region showed the presence of what was supposed to be a small foreign body. The man was anesthetized, and a broken knife-blade two and three-fourths inches long by five-eighths inch wide was extracted. The blade had traversed the left orbit without wounding the eye, muscles, artery, or nerve, had crossed the nasal fossa, and entered the right orbit, and had produced no symptoms denoting its presence.—*Pop. Science News*, October, 1887.

NOTES AND COMMENTS.**Treatment of Gonorrhœa in Women.**

In the *Medical Chronicle*, October, 1887, Dr. W. J. Sinclair quotes Schwarz's treatment for an acute attack of gonorrhœa, with the view of preventing an extension of the specific inflammation beyond the vagina to the uterus and appendages. This treatment consists essentially in first swabbing out the vagina with cotton-wool, wet in a 1-1000 solution of bichloride. A Simon's speculum is used, so that the parts can be clearly seen, and be so distended that no fold or crevice will escape the germicide. Special care is to be taken of the introitus, which contains numerous follicles.

"The next step is to copiously dust the vagina and vulva with iodoform, which is still more effectively applied by rubbing it into the mucons membrane with the tip of the finger. To complete the process, the vagina is packed, with moderate firmness, full of iodoform gauze. If the treatment is very painful, a thing which depends upon the intensity of the disease process, and the idiosyncrasy of the patient, a narcotic or anæsthetic must be administered. The process is of value only when thoroughly carried out, but then it is certain to succeed.

If, as is usual in rubbing the vagina, there occurs extensive capillary hemorrhage, it is only a favorable sign, inasmuch as it shows that at the bleeding points the diseased epithelial covering is for the most part removed, and, at the same time, a large number of the superficial capillaries, which are perhaps diseased, are destroyed.

The iodoform gauze is permitted to remain for three or four days, and then the whole process is repeated with the same thoroughness, and over the same area. After four or five days more the gauze is finally removed, and then, for eight to fourteen days, the patient carries out a copious irrigation of the vagina with a sublimate solution of 1 in 2000.

This process was hardly ever known to fail. The vagina is red and raw after the second tampon has been removed, and there is usually a copious purulent discharge, but the gonococci are annihilated, and have forever vanished."

It may be fairly doubted whether any but German patients would submit to such treatment—they certainly would not outside of a hospital. A method of treatment formerly much in vogue at the Philadelphia Hospital of this city, consists in first syringing

out the vagina thoroughly with hot water containing bichloride, and then packing the vagina full of strips of patent lint, which have been previously well dusted with iodoform. Under this treatment, combined with rest and proper food, very few patients, who applied for treatment with an acute attack, were not well in four or five days, or a week.

Dr. Sinclair, who does not recommend Schwarz's treatment, regards gonorrhœa as primarily a disease of the uterus, and therefore injects into it the pure tincture of iodine through a Fritsch-Bozeman sound. This application, he says, should be repeated three days in succession, if no symptoms arise. The vagina may be protected from the iodine as it returns from the uterus by rapid and frequent changes of pledgets of cotton wool, or by constant irrigation with warm water. Vaginal irrigations are continued after the injections of iodine have been discontinued. After the lining of the uterus has broken down from the effects of the iodine, and is more or less expelled, the process of injecting iodine is repeated.

Ninety Bothriocephali Discharged from One Patient.

The *British Medical Journal* says: In the *Correspondenzblatt für Schweizer Aerzte*, August 15, 1887, Dr. Roux, Surgeon of the Cantonal Hospital, in Lausanne, describes a singular case in which the patient, a girl, aged 21½, discharged (after two doses of 90 grs. of extract of male fern) at least ninety bothriocephali lati. The worms passed out in a bundle, the patient assisting the delivery by tearing the package with both her hands, and at the same time uttering shrieks like a woman in labor. The agonizing delivery lasted ten minutes. The mass of parasites filled up a half of a chamber utensil. The disentangling and counting took exactly four hours and a half of the author's time. Numerous very long ribbons, which did not answer the necessary conditions, were left out of the reckoning; neither were any of the ribbons, which had been discharged several times by the girl for a couple of weeks previously, taken into account. There could be no doubt, therefore, that the number of worms, given as ninety, in reality far surpassed that figure. Except some slight nervous phenomena (such as occasional headaches, vivid dreams, *semi-somnambulisme*), the patient did not present any morbid symptoms. She was a robust and ruddy, and even cheerful and active, country girl, with excellent appetite and

digestion, and with 95 or 97 per cent. of hæmoglobin in her blood (as Gowers-Sahli's hæmoglobinometer showed). The case seems to give a support to Dr. Zschokke's theory, according to which the prevalence of bothriocephalus latus amongst the population residing around Lake Lemman should be attributed to the eating of infected fish, mainly (*perchette*). At least the girl, who had come to the locality from Argovia about the Easter of 1884, during a period of several months' duration, in 1886, was dining on perch (and bothriocephali) once a week, or even still more often, the patient residing at the time at Bonvard, near the lake mentioned.

This case is of great interest in view of the published statements of Reyher and Runeberg, who look upon the bothriocephalus latus as the cause of pernicious anæmia.

Iodol Collodion.

Bilteryest (*Schweiz. Woch.f. Pharm.*) makes this as follows:

Iodol.....	10 parts.
Alcohol.....	16 parts.
Ether.....	64 parts.
Gun cotton.....	4 parts.
Castor oil.....	6 parts.

Dissolve the iodol in the mixture of alcohol and ether; add the gun cotton in small portions and well divided (teased out), and shake well till dissolved. Then add the castor oil.—*Druggist's Circular*.

Complete Occlusion of the Œsophagus with a Piece of Meat.

Drs. W. H. Bobbitt and K. P. Battle, Jr., report the following case in the *N. C. Medical Journal*, October, 1887. The patient was a boy, three years of age. Eighteen months ago he drank some lye, and was troubled at times thereafter with choking, but always relieved himself without treatment. No physician had been consulted, and the site and calibre of the stricture were unknown. The last attack of this kind occurred about one year ago. Until July 30, he was able to eat anything he pleased without difficulty. On that day, while eating lean ham, at 9 o'clock A. M., he suddenly choked and afterwards could swallow nothing, not even water. Dr. Bobbitt was called in the afternoon. Next morning the child was seen by Dr. Bobbitt and Dr. Battle in consultation. He was very thirsty and greedily attempted to drink water whenever it was offered him. He would take two or three mouthfuls, and the act of swallowing

would seem to be almost complete when the water would be returned, escaping through mouth and nose. This was generally followed by attempts at vomiting, which unfortunately could not dislodge the meat. He made no complaint of pain, but on being questioned on that point he would put his hand to the region of the larynx and at times to the stomach. There was no difficulty of breathing. On making an examination no obstruction could be felt by the finger. No œsophageal bougies being at hand, a soft rubber catheter, No. 12 E, was used and was stopped at a point several inches down the œsophagus. Smaller sizes were tried, but none would go further than the first. Mackenzie's œsophageal forceps were then introduced without difficulty to the obstruction. By pressing forward its point it could be felt in the depression just above the manubrium. Small shreds of ham fibre were brought up on closing and withdrawing the forceps, but the stricture could not be cleared by repeated efforts. In the afternoon of the same day, a curved stiff wire was inserted into a soft catheter, and endeavors were made to force the morsel past the stricture into the stomach without success. The same result followed the further use of the forceps. Apomorphia hypodermically was considered and put aside from fear of its depressing effect in the patient's weakened condition, and because, the stomach having been empty for so many hours, efforts at vomiting were likely to prove as abortive as before.

Acting upon a hint furnished by the report of a case, quoted by Mackenzie, in which pepsin was thought to have digested a "large soft substance" that had become impacted in the gullet, the following mixture was made:

R Trypsin (Fairchild).....gr. xxx
Sod. bicarb.....gr. x
Aq. destil.....5i
M.

Having witnessed the digestive power of this mixture upon fibrin, it seemed reasonable to hope that it would digest the meat and relieve the obstruction. To make sure that it should reach the desired place, a small quantity of it was injected by means of an ear syringe through a rubber tube previously introduced down to the stricture. To prevent its immediate regurgitation, the tube was held in place more than ten minutes, the child of course protesting as vigorously as the presence of the tube and a gag in his mouth would admit. There being a limit to his endurance, the tube was not held in place

longer, though this would have been desirable. After the child had rested, the stiffened catheter was again tried, but could not be pushed into the stomach with the amount of force that it was thought advisable to use. A nutritive enema was ordered and three-fourths of a teaspoonful of the trypsin mixture was directed to be given every hour, with the expectation that a small proportion of it at least would remain in contact with the meat, and the patient was left for the night.

At 9 o'clock the next morning, when the child attempted to drink water, he swallowed without difficulty, just forty-eight hours after the impaction of the ham. A short time afterwards he vomited, and in the water ejected was found a number of fibres of the meat. It seems justifiable to conclude that the morsel had been so digested and softened by the trypsin that it was dislodged by the swallowing of the water.

Analysis of a Cure for Cancer.

Frank H. Moerk, Ph. G., in a paper read before the Pharmaceutical Meeting of the College of Pharmacy (*Am. Journ. Pharmacy*, Nov., 1887), reported the following result of his analysis of a black powder submitted to him for analysis by Prof. Maisch:

Moisture.....	0.99
Charcoal.....	36.82
Carbon.....	26.07
Extractive.....	6.40
Ash.....	4.35
Arsenious oxide.....	62.19
	100.00

Dr. Purcell, of Bristol, stated in a letter that this powder had undoubtedly cured many cases of epithelioma and other cancerous growths, and gave the following as the mode of application: Cover the surface lightly with the powder; apply over it, to protect the powder and keep it in place, a piece of *black* silk somewhat larger than the ulcer and made adhesive by egg albumen. Considerable pain is, of course, produced; but the first application, and all subsequent ones, is allowed to remain until the pain subsides, which will be in five or six days. A new one is then applied in the same way and repeated from time to time until an eschar is detached without force. A poultice of elm bark is applied and the ulcer allowed to heal.

It may be that the charcoal found by analysis is from *sheep sorrel*, as the person using it was known to collect that plant on different occasions. While the use of arsenious acid

for external application has long been made, yet every writer emphasizes the danger in using it where the cuticle is removed, and Dr. Purcell thinks most physicians like himself have feared to so use it for this reason.

Dr. Purcell also stated that this powder had a great reputation in the upper part of New Jersey, and that money had been freely offered to obtain the secret of its composition, but all offers had been declined.

It is probable that the previous application of cocaine with morphia would largely prevent subsequent pain from the application of the powder.

A Case of Verbal Amnesia due to Shock.

Dr. Waldo Briggs, of St. Louis, reported the following case to the *St. Louis Med. and Surg. Journal*, November, 1887: On Friday night, Sept. 30th, Mr. S., proprietor of a large cooperage at Jerseyville, Ill., after paying off his hands, found himself in possession of quite a large sum of money (between five and six hundred dollars), which had come in after banking hours. Having worked until after dark, he seated himself at his desk by a window, in full view of passers by on the street, counted his money, rolled it up and put it in his pocket preparatory to starting home. After locking up his office, he called at a grocery and bought a few articles, and then walked homeward, his residence being in the suburbs some half or three-quarters of a mile away. Just as he reached the corner of the low fence enclosing his house, and perhaps a hundred yards from his door, he was felled by a blow, delivered from behind the fence (and over the top of it), the weapon, as it afterward turned out, being a plough handle. As he fell, another assailant ran from across the street and belabored him over the head with a club made of a section of grape vine. After beating him into utter insensibility the robbers took his money and left him. Exactly how long he remained where he fell is not known, but probably half an hour. The first that was known of the affair by his family was when he staggered into the house, about 9 o'clock, covered with blood, unable to speak or to recognize any of the family, or to understand words spoken to him, but still grasping in his hands the bundle with which he started from the shop. He was hastily put to bed by the family and medical aid summoned.

An examination by the local physician disclosed several scalp wounds of greater or less severity, but no fracture of the skull.

The right parietal region seemed to have suffered the most, as it had received the first stunning blow, which was evidently delivered (taking the position of the assailant into consideration) by a left-handed man. Fortunately it glanced, and failing to crush the parietal bone, fractured the right superior maxilla badly.

Dr. Briggs was summoned, and on arriving at the house on the night of October 1, found the patient in a semi-conscious condition, apparently able to understand what was said to him, but unable to reply intelligibly, as there was total verbal amnesia, or probably it would be better to say *aphemia*. When he wished for a spoon, for instance, he would say "chair," "stove," "table" or substantives other than the correct ones; but that he knew what he wanted was proved by his becoming irritated if anything, other than the object desired, was offered him. A careful examination confirmed that of the local physicians as to the absence of fractures or other lesions of the calvarium.

During the time of Dr. Briggs' visit at the house, intelligence gradually returned to the patient, and when given a pencil and paper he managed, but very disjointedly, to make known his wants. While still unable to articulate the correct words, when he wished to express himself verbally, he was generally, though not always, able to write them. The first proper and clear answer that he was able to return was made shortly before Dr. Briggs' departure on October 2. When asked by his son if a certain suspected person was one of his assailants, he answered distinctly and without hesitation, "yes." Dr. Briggs says he has since heard from the patient several times, and the verbal amnesia has almost entirely disappeared, and the patient is rapidly recovering.

Some of the more curious features of the case are: (1) that he should in his utterly unconscious state have made his way home unaided; (2) that he should have recovered the package and carried it with him; (3) that the verbal amnesia should have extended simply to inability to speak the correct word.

—Dr. George Arthur, a passed assistant surgeon, U. S. Navy, left Washington November 2d, to go to Shelbyville, Tenn., to be married. The same night his body was found near the track of the Virginia Midland Railroad, not far from Salem, Va. It is not known how Dr. Arthur came to his death.

NEWS AND MISCELLANY.

Opium Importation.

It is stated in the *New York Commercial Advertiser* that the increase in the importation of opium is "surprising, almost startling." The Chinese Government has continued to remonstrate against the importation of opium from India, but without avail, and the importations rose from 7,055,657 pounds to 12,911,866 pounds between 1850 and 1880. It is now estimated that the amount of opium produced in Southwestern China is two and a half times the quantity imported from India. In time China will produce all the opium it consumes. Nine out of eighteen of its provinces now produce the drug, and four-fifths of the amount it consumes is now home grown. This increase is in the face of prohibiting edicts.

In the United States the amount of crude opium imported in 1872 was 189,354 pounds; in 1880, 243,211; in 1886, 471,276, and in 1887, 568,263 pounds. The years end June 30. The writer says: "Among the Buddhists, Moslems and Hindoos, to whom alcoholic beverages are prohibited and whose religious rites necessitate extended fasts, it is much used. Opium eating is chiefly practiced in Asia Minor, Persia and India, smoking in China and in the islands of the vicinity. Opium differs widely in its injurious effects, according to which of these different ways it is adopted. The weight of opinion is that smoking is the least injurious. The greatest per capita consumption of opium in the United States is in the city of Portland, Maine, a stronghold of prohibition. In India its sale is so great that there are stores which sell it exclusively. In this country its general sale is prohibited by law, but the law is not so strictly enforced but that it is easily obtained.—*Phila. Ledger*, Oct. 17, 1887.

The Quain Bequest.

Mr. Richard Quain, F.R.C.S., F.R.S., bequeathed almost the whole of his fortune, amounting to about £75,000, to University College, London, subject to certain annuities to family connections. The College will, we are informed, at once benefit to the extent of about £60,000, which sum is left to four trustees, to apply the annual income in "the promotion and encouragement in connection with University College, London, of general education in modern languages (especially

the English language and composition in that language) and in natural science." The trustees, Lord Justice Fry, Sir William Jenner, Mr. George Brodrick (the Warden of Merton), and Sir George Young, are authorized to carry out the testator's wishes, "either by salaries or other payments to those who teach, or by endowing professorships, or by pecuniary aid to those who are being taught, as by endowing scholarships or fellowships, or in any other manner in which the trustees may in their absolute discretion think proper," and they are requested to place themselves in communication with the Council of University College, with a view to preparing a scheme for carrying out the objects of the bequest. The testator desires that in any statement of the foregoing bequest the name of his brother, the late Sir John Richard Quain, shall be associated with his name.—*Brit. Med. Journ.*, Oct. 8, 1887.

A Good Place for Doctors.

The Evening Telegraph, of Philadelphia, says: Next to the undertaker's bill, the last it is within the disposition of man to pay is the doctor's dues. Gentlemen of the medical profession complain constantly that when a man gets well he forgets his physic. The perpetual invalid is the only patient who is always at the doctor's mercy. He must pay his bills or die. This is so the world over—except in Washington. Here there is a class of patients who would go half-starved for a week to pay their physician. Their board may go unpaid, they will do without a new gown or trousers—whichever they wear—and make even their washerwomen wait, but never the doctor! They will stint themselves and all their other creditors in the interest of their family physician. These patients are the Government clerks. They sometimes find it hard to keep the wolf from the door—or the creditor from the Department. The tailor, the milliner, the landlord, the milkman, the butcher, or the man who sells them sour bread for breakfast, may watch and wait in vain, but they will run after the doctor eagerly to pay him for a dose of physic! He holds a mysterious influence over them. They can't draw pay from the Government for the time they have spent in the sick-bed unless the doctor says so, and he won't say so until sure of his bill.

German Hospital.

—Thanksgiving Day, November 24, 1887, will be observed as Donation Day at the German Hospital, in Philadelphia.

Wholesome Advice.

Dr. J. E. Graham, of Toronto, in his address as President of the Canadian Medical Association (*Canada Medical and Surgical Journal*, October, 1887), took occasion to caution the members against the dangers of overwork, which too many ambitious medical men encounter, and told the following story in point of Dr. Golding Bird:

Dr. Routh, in his book on overwork, gives the following account of an interview with that distinguished man: "I well remember a conversation I had with the late Dr. Golding Bird a few weeks before his death. He was then in the zenith of his popularity, and recognized by all as one of the ablest of our London physicians. I called upon him one morning with a relative to consult him. Several other medical men preceded me. His rooms were full, and I had to wait three hours ere I could obtain admission to his study and consult about the case. I congratulated him on his success in practice. 'Yes,' he said to me, 'you are right; but I wish, nevertheless, to make your remark a text for a little parting advice. You see me at a little over forty in full practice, my rooms full, and making my several thousands per annum' (I think he said seven), 'and if I die to-morrow I do not leave as many hundreds to my family. All this I have done by sheer perseverance, unceasing hard work, and no holiday. But I am to-day a wreck. I have fatal disease of the heart, the result of anxiety and hard work. I know that I cannot live many months, and my parting words of advice to you are these, never mind at what loss, take your six weeks' holiday. It may delay your success, but it will insure its development. Otherwise you will find yourself at my age a prosperous practitioner, but a dying old man.' Six months after this conversation he had put off this earthly tabernacle."

Dr. Graham continues: "It is my opinion that in such cases it is not the scientific labor which is the cause of trouble, but it is the worry, anxiety and fatigue of family practice, in addition to the scientific work. We all know from personal experience how exhausting it is to visit day after day, upon a serious case of illness, especially if the patient is a near friend, or one of distinguished position in society. The amount of vital capital lost in these cases cannot be estimated. It is a singular fact that the large majority of cases of overwork occur among consulting physicians. Surgeons and specialists do not suffer to the

same extent. The reason of this is not far to seek. The amount of brain work done by the physician, as a general rule, is very much greater than that done by the surgeon or specialist. The work of the latter, in most cases, is largely of a mechanical nature, and a great portion of their time is spent in manipulation. It is otherwise with the physician. Let us for a moment follow him in his every-day work. He must first attend to his correspondence. This is usually no slight task, especially if he answers all the letters sent by brother practitioners throughout the country."

"After the physician has finished his correspondence he is ready to receive patients. Together with a number of minor cases he may have two or three of difficult diagnosis, which may bring into exercise all his resources. He will write a detailed history of each case, and, perhaps, afterwards write his opinion and treatment in a letter to the attending physician. When he has finished a morning's work of this kind he is frequently so exhausted as to wish for the afternoon to rest. But he must then go to the hospital and, perhaps, for one or two hours he examines and tries to make clear to a class of students cases quite as difficult as those of the morning. He then visits his private patients. (On this continent we have yet very few purely consulting physicians.) This may occupy his time until six or seven o'clock. After dinner, he works at his lectures or other literary matter, and is at the same time harassed by numberless interruptions until nearly midnight. Then he may, like all medical men, be called up at night, or, if allowed to sleep, wakes up, perhaps tired, to continue his ceaseless toil. Is it any wonder that so many break down under such a strain?

The development of specialties has also added to the work of the physician. He cannot act simply as a distributing centre, sending one patient to this specialist and another to that; but he must learn to diagnose and treat many local diseases himself. This entails upon him the necessity of acquiring a knowledge of most of the specialties; and now, that familiarity with bacteriology is added as an almost necessary accomplishment, the field is too vast to contemplate.

The lessons to be learned from all this are:

1. That the rapid acquirement of a large and lucrative practice is often a great misfortune. It subjects the physician to the enmity of his older colleagues, often with and often without reason. It imposes burdens under which many fall, and it robs him of a happy and useful old age.

2. In the case of those who are ambitious to acquire professional favor for scientific work, the lesson is to avoid over work. One ought not to try to become a noted physician and a rich man at the same time. It is a rare thing for a physician to amass a fortune: too rare to make it worth one's while to attempt it.

A very important lesson is to notice the first admonition of a general break-down, and to act upon the warning given. One of the best remedies is a prolonged holiday. This serves the purpose of giving the mind a complete rest. A long holiday is but of temporary benefit; the work must be cut down at home. Eight hours' sound sleep must be had at any cost. If the rest is broken by night calls, it must be made up in the morning. Some part of each day should be devoted to recreation. These are difficult rules to follow out in practice, but they are quite possible when a determined stand is taken.

Those who habitually over-work must remember that they are thus defeating the very object of their ambition. In the medical profession the best work should be done between 45 and 55. The late Dr. Flint did not issue his celebrated work on "Practice of Medicine" until he was over 50. We know from observation that medical men in health are at their best during those years. This being the case, it should be the aim of an ambitious physician, above all things, to maintain his health and vigor until he can reap the fruit of his earlier labor.

The most satisfactory, the most lasting, and the best work is done by those who are careful not to overtax themselves, but who so arrange their business as to take that recreation which the body so much needs.

I would not close this address without referring to the opposite condition: the spirit of apathy and inactivity which blights many physicians' lives. It is far better to live an active life of usefulness, even if one should be the sooner cut off, than to pass through this world as a miserable drone, of little use either to the family or community.

Our active professional and business men, those who shape our destinies as a nation, frequently exhibit one trait of character which might almost be considered a failing, viz., the expectation of immediate results from their labor. This is particularly noticeable in our western provinces and territories. We work hard, and if in a few years the reward of our toil is not within our grasp we chafe under the disappointment, become discontented, and determine either to change

the political character of our country or remove to lands where fortunes are said to be more rapidly made.

We have a vast territory, but one in which the material obstacles to rapid advance are great. These very difficulties ought to develop in us qualities of patient endurance and steady perseverance—qualities which will ultimately make this Canada of ours one of the greatest nations of the world.

Let us as physicians, not under the influence of haste and worry, but steadily and perseveringly, work in building up our own profession, so that in all matters which pertain to excellence we may be equal to that of the foremost nations."

The State Board of Health.

The regular meeting of the State Board of Health was held in Harrisburg on November 9, 1887. There were present Drs. Engelman, President; Lee, Secretary; Edwards, Dudley and Murphy, C. E. In his third annual report, Secretary Lee referred at length to the death of Dr. Germer, the first President of the Board, and paid a high tribute to his memory. Dr. Lee says that at no time in his experience of ten years as Secretary of the Board have there been twelve months of such remarkable immunity from pestilence. The Secretary says one of the most important practical questions confronting the Board is the quarantine of the Delaware river, a matter which demands earnest attention. He recommends that the Board should urge upon Governor Beaver the importance of at once conferring with the Governors of Delaware and New Jersey, with a view to making joint application to the President of the United States for the grant of such portion of the reserve funds placed in his hands by Congress for meeting emergencies like the present, as may be necessary to immediately establish a National Quarantine Station, either at the site of the present Marine Hospital at the Delaware Breakwater, or Pea Patch Island, which station shall provide ample accommodations for quarantine purposes, as well as be supplied with all the modern appliances for disinfection of ships, cargoes, baggage and clothing.

—Chinamen who are fortunate enough to find a wild ginseng plant need not do any work for a year. The wild roots are worth from \$50 to \$100 an ounce. The cultivated root, however, is not worth more than from \$1.25 to \$2.00 per pound.—*West. Druggist.*

Items.

—William S. Stokley, Director of Public Safety in Philadelphia, has recommended that the Municipal Hospital be removed from Twenty-first and Lehigh avenue to the Lazaretto. It would be better to consolidate the Municipal and Philadelphia Hospitals, having a special department for contagious diseases, and remove the Almshouse to the House of Correction grounds.

—The *Philadelphia Ledger* states that Dr. S. Weir Mitchell, who is becoming as well known in secular as in medical literature, will shortly publish a novel called "In the Far West," the scene of which is laid in Elk and McKean counties, Pennsylvania, as they were sixty years ago. Dr. Mitchell has also just completed a volume of essays entitled "The Doctor and Patient," which is said to be intended chiefly for women, and to discuss the subjects in a popular rather than in a scientific way.

OBITUARY.

DR. WILLIAM ARMSTRONG.

Dr. William Armstrong, a retired physician and druggist, who was active in many charitable and reform movements in Philadelphia, died November 3d, in his eighty-seventh year.

DR. WILLIAM SELDEN.

Dr. William Selden, an old and prominent citizen of Norfolk, Va., and the wealthiest capitalists in this section, died Nov. 7th.

Dr. Selden was born in Norfolk, Va., in 1808. He studied at the University of Virginia, and took his degree of M. D. at the University of Pennsylvania, in 1830. After spending two years in study in the hospitals of Paris and London, he established himself in practice at Norfolk. He was a surgeon in the Confederate army, and had made a number of contributions to medical literature, among them a "Report on the Yellow Fever in Norfolk and Portsmouth in 1855."

DR. WILLIAM O'GORMAN.

Dr. William O'Gorman, one of the leading surgeons of the United States, died in Newark, N. J., November 10th, 1887, aged 63 years. He was born in Ireland, and graduated there, but came to this country in 1849. He was chief of the New Jersey medical staff during the war. He had been president of the State Medical Society and of the Essex County Medical Society, and was called in consultation when

President Garfield was shot. Dr. O'Gorman was brought prominently before the world two years ago through his connection with M. Pasteur in his treatment of the Newark hydrophobia patients.

DR. JOHN K. LEE.

Dr. John K. Lee, a well-known homœopathic physician, died in Philadelphia, November 10th, aged sixty-three years. He was born in Meadville, Crawford county, this State. He graduated in medicine in this city in 1851, and had been in active practice ever since. About three years ago Governor Pattison appointed Dr. Lee to the unexpired term of a member of the State Board of Public Charities, and he has been a member of that body ever since.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Nov. 6, 1887, to Nov. 12, 1887:

Major Chas. R. Greenleaf, Surgeon. Par. 8, S. O. 248, A. G. O., Oct. 25, 1887, directing Surgeon Greenleaf to visit the recruiting depots and rendezvous at certain places, is amended to include Davenport, Iowa; Quincy, Ill., and Evansville, Ind. S. O. 257, A. G. O., Nov. 4, 1887.

Capt. Leonard V. Loring, Assistant Surgeon, ordered for duty at Fort Mogave, Ariz. Ter., upon the expiration of his permit, with leave of absence. S. O. 258, A. G. O., Nov. 5, 1887.

Capt. Harry O. Perley, Assistant Surgeon, now on duty at Fort Wayne, Mich., ordered for temporary duty, with troops stationed at Highwood, near Chicago, Ill. S. O. 258, A. G. O., Nov. 5, 1887.

First Lieutenant F. J. Ives, Assistant Surgeon, granted leave of absence for one month, to take effect on or about the 15th inst. S. O. 113, Dept. Platte, Nov. 5, 1887.

List of Changes in the Medical Corps of the U. S. Navy, during the week ending Nov. 12, 1887:

Surgeon T. C. Heyl, detached from the "Marion," proceed home and wait orders.

Passed Assistant Surgeon T. C. Craig, detached from the "Marion," and to proceed home and wait orders.

Medical Inspector H. M. Wells, detached from the "Trenton," and to proceed home and wait orders.

Medical Director Geo. Peck, ordered to Washington, D. C., as member of Examining Board.

Surgeon Jas. G. Ayers, ordered to the "Galena" to relieve Surgeon F. L. Du Bois.

Surgeon F. L. Du Bois detached from the "Galena," and to proceed home and wait orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, two weeks ended Nov. 12, 1887:

Walter Wyman, Surgeon, to proceed to Louisville, Ky., and Memphis, Tenn., as Inspector. Nov. 12, 1887.

F. M. Urquhart, Passed Assistant Surgeon, relieved from duty at Cape Charles Quarantine, ordered to Norfolk, Va., Nov. 6, 1887.

G. M. Magruder, Assistant Surgeon, when relieved to rejoin station at Chicago, Ill., Nov. 3, 1887.

EPILEPSY, SUDDEN DEATH IN A
COMATOSE CONDITION, NO LESION
DISCOVERED AT THE AUTOPSY.
—INFLAMMATION OF APPENDIX
VERMIFORMIS, FOLLOWED SEVEN
MONTHS LATER BY ULCERATION,
RUPTURE AND DEATH.

A Clinical Lecture delivered at the Hospital of the
University of Pennsylvania by WILLIAM PEPPER,
M.D., LL.D., Provost and Professor of
the Theory and Practice of Medicine
and of Clinical Medicine in the
University of Pennsylvania.

REPORTED BY WILLIAM H. MORRISON, M.D.

GENTLEMEN: I wish in the first place to call your attention to these specimens which were removed from a case which has lately died in the hospital. The patient was an epileptic. He had been subjected to various methods of treatment, and was admitted to the hospital with the hope of benefiting him, if that were possible. He had epilepsy very badly. The attacks occurred four or five times a day, and were increasing in severity. The patient's mind was failing under the influence of the disease. As I have already said he had been treated in all ways, but at no time had he been benefitted. He was unable to work, and was becoming more and more feeble-minded. The patient was before you on one occasion, and at that time I said that occasionally in cases of this kind, where the ordinary measures of treatment fail to arrest the attack, by a course of

treatment which would produce a radical and profound effect upon the whole nutrition, there would be a change in the symptoms. We therefore proposed to put the man to bed, and keep him there for a long time, and to place him upon a carefully restricted diet, gradually reducing it so as to effect as far as possible a complete revolution and a re-creation of the entire frame. We placed him in bed and gave him moderate doses of antipyrine, the influence of which over vaso-motor phenomena would indicate that it might be serviceable. He was given eight grains of antipyrine three times a day. I am sorry to say that this proved of very little service. The man was very rebellious as regards diet, so that practically we were unable to restrict his food. He was willing to lie in bed as long as he was well fed, and the fact is that he increased in weight while under treatment. As the man lay in bed he looked in perfect health, with no sign of depression or debility about him, and this continued until very shortly before his death.

The use of antipyrine was begun on October 2, and continued until October 13. As it accomplished nothing it was stopped, and antifebrin in three grain doses, three times a day, was substituted. As the convulsions still continued severe, he was placed upon a preparation of the bromides, containing five grains each of the bromides of potassium, sodium, and ammonium, with fifteen drops of hydrobromic acid, three times a day. This was given in conjunction with the antifebrin. The paroxysms were not materially influenced, and the antifebrin was cautiously increased until eight grains

were given three times a day. Under this treatment the convulsions steadily decreased in number, so that from October 21 to November 3, a period of two weeks, he only had twelve convulsions; whereas, during the previous two weeks, he had had twenty-one attacks.

On November 1, the antifebrin was reduced to two doses a day, and the bromide mixture was only given twice a day. The man remained quiet in bed, and continued to do well. On the morning of November 3, he attempted to rise from bed for some purpose, and fell back unconscious, and continued unconscious from this time until his death, sixteen hours later. He was in a condition of complete coma, with stertorous breathing, and for the first time since his admission, with but one exception, there was a rise of temperature, from 98.5° in the morning to 102° in the evening, and at the time of his death it was still rising. Upon one other occasion he had had for a short time a temperature of 101.2° , apparently due to some temporary disturbance. Since his death his wife informs me that on four previous occasions this man had suddenly passed into an unconscious condition, and continued in this state for twenty-four hours. It was thought on each occasion that he would die, but he had gradually regained consciousness, and recovered his usual health.

A careful post-mortem examination was made. What should we expect to find in such a case? We are to remember that here we had a man who had for a long time suffered with convulsions which had been increasing in frequency and severity, and that he complained a great deal of headache. When we came to ask ourselves the question whether or not there was some intra-cranial disease or tumor which might cause both the convulsions and the headache, the answer was in the negative. There was no history of syphilis or of traumatism. The ophthalmoscopic examination was negative. There was no paralysis of any cranial nerve. There was nothing to point to lesion within the cranium as the cause of the trouble. There was no lesion of the kidneys, nor of the spleen. We therefore came to regard the case as one of essential epilepsy. Yet when I heard that the man had fallen into this unconscious state, not knowing at that time that he had had previous similar attacks, I naturally suspected that there would be found some aneurism or other intra-cranial lesion. The results of the post-mortem examination were entirely negative.

No lesion was found anywhere to explain this sudden death. There was no heart-clot, no slight effusion, no small hemorrhage; nor does the mode of death throw much light upon its cause. The patient did not die from paralysis of the heart, and this is an important thing to note. The heart remained strong to the very last, and he evidently died by the brain, the respiration and the circulation continuing good to the very end.

You will at once see that I dwell upon these facts in consequence of the remedies which this man had taken, for in any given case the question must arise whether or not the drugs which have been administered could have caused the sudden death. This is particularly true when we have been giving such drugs as antipyrine and antifebrin, which if pushed beyond a certain limit do exert a depressing influence upon the heart. Cases are beginning to accumulate in the journals in which the use of large doses of these drugs has been attended with symptoms of cardiac failure and of failing circulation. You will see that in this case we can scarcely assign to these drugs any part in the event. In the first place, at no time did he take a dose which would be sufficient to depress the heart and circulation. He was a strong, muscular man, with a healthy heart; further, he was lying in bed making no muscular exertion. At no time did the dose exceed eight grains of antifebrin three times a day. This may be said to be a perfectly safe dose under the circumstances. While taking it three times a day he bore it perfectly. Since November he took it only twice a day. Finally, in the events of the day, there was not the slightest evidence of depression of the heart or of the circulation. The symptoms were not those of cardiac failure, but those of sudden paralysis of the brain, a sudden cessation of nervous action, unconsciousness, profound coma and gradual failure of cerebral power. We may, therefore, say that neither the bromide, the antipyrine, nor the antifebrin had any influence in the production of the fatal result. It is important to dwell upon this because we desire to learn what are the limits of safety of these drugs. It is proper that we should scrutinise every case where new drugs are given, and where such a dramatic end occurs, to see if the drugs have had any part in the production of the result.

There are many chronic diseases in which sudden death occurs. It may take place in Addison's disease from heart failure under exertion. In the same way, sudden death

may occur in leucæmia from the watery state of the blood and the exhausted condition of the heart. In other cases, sudden death occurs from the development of some constitutional condition of a highly complex character, as we see sometimes in diabetes. At times, a patient with diabetes, who has apparently been doing well, will suddenly become delirious, pass into a condition of coma, with rapid rise of temperature, and die within twenty-four hours. This mode of dying is far from rare in diabetes, but it has not yet received a satisfactory explanation. It is clear that there is developed some highly complicated product of nutrition, which, acting upon the nervous system, causes death as does the ingestion of some fatal poison. A perfectly satisfactory explanation of these cases of sudden death has not yet been found. You will observe that in this case, the patient died with a rapid rise of temperature and with symptoms of arrest of the circulation of the brain. This man did not die from the effort to rise in bed. This was not a syncopal attack from failure of the heart. The probability is that he attempted to rise from bed because he felt uncomfortable and was overcome by the unconsciousness before he could get on his feet. This has occurred from some profound nutritional change associated with a morbid vaso-motor state in which failure of the cerebral circulation occurred with complete unconsciousness, attended with derangement of nutrition throughout the body, marked by fever, excited circulation, continued unconsciousness, coma and rapid death. We cannot explain it. No gross lesion presents itself.

Observe that he had four preceding similar attacks, all of the same nature. He was in all suddenly seized with unconsciousness and coma, apparently going to end in death, but out of which he rallied. This case is of interest in many ways; of interest from the fact that these new and powerful drugs had been administered, but they cannot be held in the least responsible for the result. It is also of interest, because we have here a case of sudden death in which careful examination fails to reveal a satisfactory explanation.

Inflammation of the Appendix Vermiformis, Followed Seven Months Later by Ulceration, Rupture and Death.

Very different are the other specimens which I have to exhibit. These were removed from the body of a young man 18 years of age, whom I attended last March, with an attack of acute obstruction of the bowels.

The obstruction was absolute and was marked by severe pain a little to the right of the median line and low down toward the hypogastrium. The fever was moderate. The belly was distended, and there was tenderness on pressure, which was more marked in the region above-mentioned than at any other point. There was no distinct indurated mass to be made out in any position. The diagnosis was circumscribed acute peritonitis, with accumulation in the bowel close to the cæcum. It is not difficult to see why this diagnosis was formed. The patient was rather too old for intussusception of the bowel, and this accident is usually attended with a demonstrable fullness and hardness in some part, and there is not the rapid development of peritonitis that occurred in this case. Moreover, in this case, vomiting was not so urgent as it becomes in intussusception, where it is frequently repeated, and if the obstruction is not relieved, soon becomes fecal. Examination by the rectum failed to reveal anything. When the intussusception is extensive, it is not uncommon to feel the volvulus when a rectal examination is made, and often a little bloody mucus escapes. The symptoms of intussusception were therefore wanting in this case.

It was not a case of ordinary impaction of the bowel. There was no demonstrable mass, and the symptoms of inflammation were too marked and came on too abruptly. The pain was also too severe. Nothing would explain it but peritonitis. The inflammation was not associated with typhlitis or perityphlitis, for there was no induration, and the position of the pain was more toward the median line than it would be if the inflammation were located in the cæcum. In perityphlitis, we find in the region of the cæcum an area of distinct hardening, with sometimes a slight prominence. This was wholly wanting in this case. We feared at the time that the appendix vermiformis might be involved in the inflammation. It could not be felt by a rectal examination.

The patient was kept in bed and quinine and opium given by the rectum. Minute doses (one-twelfth of a grain) of calomel were given by the mouth, simply placed dry upon the tongue, but not a drop of water or a particle of food was given for several days. Little pieces of ice were allowed to melt in the mouth, but opium was depended upon to blunt the sensation of thirst. He remained in this condition for nine days without passing even flatus by the bowel. Then flatus was passed, and on the tenth day an enema secured a movement, and after that

convalescence was rapid and apparently complete.

It was therefore evident that whatever had been the cause of the obstruction it had ceased to exist. The lad continued perfectly well all summer, spending his vacation in hunting and fishing. In the fall he returned to his duties apparently in perfect health. Ten days ago, he was suddenly seized with agonizing pain referred to the lower zone of the abdomen. The pain was so severe that he rolled and writhed on the floor, and four large hypodermic injections of morphia were given before any relief was obtained, but at no time during the whole of his illness could a sufficient amount of opium be given to entirely relieve his suffering. There was an immediate and progressive rise of temperature. It gradually rose, and when I saw him in consultation, four days after the onset of the pain, it was 104.6° , and on the following night it was 107.5° . There was with this a corresponding increase in the rapidity of the pulse which became running and small. Vomiting was not frequent: it occurred once or twice in the beginning; the stomach then became quiet, but the vomiting recurred once or twice toward the close of the case. At no time was the vomiting such as we have in mechanical obstruction of the bowel. Nothing like faecal matter was vomited, yet from the time that he was taken, until his death, no flatus passed through the intestine. The bowels became rapidly distended, and the colon and the coils of the intestine could be distinctly seen through the stretched abdominal walls. The urine was secreted freely and was perfectly normal. It was passed frequently owing to the irritation of the bladder. I at once made an examination of the rectum. The bowel was entirely empty, and the roof of the pelvis was found to be uniformly hard, instead of soft and yielding.

The question of diagnosis again arose, and it was impossible not to connect this second attack of acute peritonitis and obstruction of the bowels with the previous one. This made it the more certain that the first attack had not been one of intussusception. If it had been, it would not have recurred. It was not a case of impaction, for the symptoms were too sudden and too violent. It was not a case of typhlitis, for there was no local induration. Rectal examination showed no greater fullness on the right side than on the left. It was possible that in the former attack there had occurred, between two inflamed coils of intestines, a band of organized lymph which had become

stretched, and that a portion of the intestine had passed into this loop and become strangulated, thus causing an internal hernia. I have seen this accident occur on several occasions. In opposition to such a view was the fact that the peritonitis was immediate and severe, and had almost at once followed the attack of sudden pain. Had this been a case of mechanical obstruction, the symptoms of peritonitis would have appeared more gradually. Again, as I have already pointed out, the vomiting was not such as accompanies mechanical obstruction. It did not recur frequently, and at no time were any of the contents of the bowel brought up. All these things were against the view of an internal hernia.

It therefore appeared probable that the portion of the bowel which had been involved in the previous attack of inflammation had now perforated, and that general peritonitis had followed. Your studies in pathology will teach you that such perforation most frequently has its seat in the appendix vermiformis; so that this attack naturally connected itself with the explanation of the attack of last spring.

The question of laparotomy was seriously discussed, but it was clear that the peritonitis was so intense that the operation was inadmissible. Death occurred at the end of the fifth day of the attack.

The autopsy was made twenty-four hours after death. I have in my hand a coil of the intestine, showing the character of the peritonitis. There is a thick layer of yellow lymph, looking like buckskin, covering the intestines. The abdomen also contains pus and serum. The intestines were everywhere matted together, forming little pockets, containing pus and serum. The peritonitis was especially intense in the pelvic segment. At the point where the pain had been so intense last spring, there was a cluster of coils of intestine strongly adherent. So close were these adhesions that some of them evidently dated back to the first attack. In addition, there were other adhesions resulting from the recent inflammation. The vermiform appendix was covered by a cap of adherent intestines. It was purplish in color, was distended and swollen. Close to the cæcum it was nearly severed by gangrenous ulceration. There was a perforation into which the thumb could be placed. The mucous membrane of the appendix was rough and thickened. The opening of the appendix into the cæcum had been completely closed by the previous inflammation. The pus from this perforation had in conse-

quence of the dense adhesions around the appendix burrowed in different directions, and there was no circumscribed collection of fluid at the site of perforation.

Here, then, we had a case of simple appendicitis last spring, with peritonitis, gradually terminating by resolution, leaving adhesions. The appendix, however, remained inflamed, but producing no symptom, and gradually went on to ulceration and rupture. Careful search was made for any concretion that might be present, but none was found.

This case of perforating appendicitis is of special interest. It is almost unique in the fact that it clearly followed upon an attack of simple inflammation of the appendix, and it warns us how careful we should be in the after treatment of any case of inflammation in the cæcal region. It is perfectly true that in the present instance nothing was left undone that suggested itself as desirable. I do not see how it would have been possible to have anticipated, or to have averted the fatal result. This case impresses upon us most strongly the fact that in these cases of disease of the appendix there is nearly always, if not always, a pre-existing, insidious, unsuspected inflammation. There may be a little catarrh of the lining membrane of the appendix, which does not reveal itself by any symptom. There may be an occasional slight twinge of pain, which does not attract special attention. There may be gradually forming a little concretion, which will kill the person in twenty-four hours. The concretion gradually increases in size, until its irritation leads to ulceration and perforation; giving rise to violent pain and severe peritonitis, which is one of the most rapidly fatal forms of peritonitis with which we meet.

This catarrhal inflammation of the appendix may come from wrenches, from strains, or from over-exertion. In the case which I have described there is reason to think that the starting point of the inflammation was violent over-exertion and over-heating in base ball. This acute inflammation once started, may run into the chronic form, ending in perforation. During the progress of the chronic inflammation, a concretion forms varying in size from a very small body up to a cherry stone or a date seed. This sometimes is made up of dried mucus, or it may have as a nucleus a small seed or other foreign body which has found its way into the appendix. You will observe that in this case the opening into the cæcum had been closed by inflammation. This, of course,

formed a closed abscess. The presence of pus and decomposing matters would naturally excite inflammation and a tendency to perforation.

In the treatment of such a case as this, it is perfectly clear that there is only one thing that will give the patient a chance, and that is instant laparotomy; but how are you to assume the responsibility of opening the abdomen in such a case within a few hours of the commencement of the attack? And how will you be able to convince the family that what seems like an ordinary colic, is a deadly disease which can only be met by one of the most dangerous operations in surgery? You can not be sure of your diagnosis, and even when you have good reasons for suspecting this accident, you can not demonstrate it. For these reasons, I fear that we shall never be able to perform laparotomy early enough to save our cases of perforating appendicitis. The only thing to be done is to open the abdomen within twelve hours, locate the appendix, ligate it with antiseptic ligatures, remove the distal portion, and introduce a drainage tube, or if the ulceration is so close to the cæcum as to preclude the use of the ligature, make a fæcal fistula.

The general symptoms are not sufficient to enable you to recognize the trouble. The pain may be more marked on the right side, but it spreads to other parts of the abdomen and the symptoms of peritonitis soon become general.

One of the cases of perforation of the appendix, which I attended during this summer, was in a young man who was believed to have been in perfect health, until the beginning of his last illness, which terminated fatally within seventy-two hours. A neighbor's house catching fire, he went to afford what assistance he could, wrenched himself in the side and had some pain. The next day symptoms of peritonitis appeared, and I saw him thirty-six hours after the accident. I considered it a case of perforating appendicitis and suggested laparotomy. It was agreed that if the patient were no better, the operation should be performed the following morning. The operation was performed, and the drainage tube was passed into a cavity full of pus. It was then supposed that the case was one of perityphlitis. The patient, however, died, and at the autopsy the appendix was found in a state of gangrene, with the evidences of old catarrhal inflammation which had been there for months. This is only one of a number of cases which I have seen. In

this case the operation was done within sixty-four hours after the onset of the symptoms, and this has been the earliest that I have ever been able to have the operation performed.

One of the most important diagnostic measures in these cases is the rectal examination, and in no cases where a trouble of this kind is suspected should the rectal examination be postponed one hour, but, on the other hand, it should be frequently repeated. The moment that, by rectal exploration, we are able to detect the slightest fullness in the cæcal region, laparotomy should be performed. In the case from which these specimens were removed, a rectal examination within eighteen hours of death failed to reveal any difference between the two sides. The reason of this is evident, for the adhesions were so dense as to prevent any accumulation of pus.

COMMUNICATIONS.

IMPROVED SPLINT.

BY D. BENJAMIN, M.D.,

Physician to the Cooper Hospital, Camden, N. J.

This splint, called the "Day Splint," with double inclined plane, has been in use in hospitals and private practice for many years, and is considered by many surgeons the best splint that can be used for fractures of the lower extremities. It has some advantages, viz.: In treating compound fractures it will permit the surgeon at all times to inspect the injuries to the soft parts, as they can be treated on this splint without bandaging. It also has the advantage of the hinge at the apex of the frame, under the knee, which permits the passive movement of the joint, without permitting the movement of the fragments of fractured bones.

The mechanical principles upon which it is constructed are correct, but the methods used in its construction are defective. The splint would, no doubt, be more extensively used were certain objections and imperfections in its mechanism overcome. In the first place, there are no adequate means of keeping the heel of the splint in the notches, and it has been the experience of every surgeon who has used it that, notwithstanding the most careful tying, it will frequently slip out, letting the leg suddenly down straight, thereby bruising and deranging the ends of the bones.

The second objection is that the movable foot piece does not come down low enough towards the bottom of the heel, to make traction in the line of the long bones, but makes its traction upon the foot, about opposite the ball of the big toe, thereby bending the ankle unnecessarily and uncomfortably, and producing inefficient traction.

Objection third: That the foot piece wobbles from side to side, and unless great care is used in managing the screws, would be so loose as to cause a rolling of the foot and, consequently, an irritation of the wounds, and a rotation of the lower fragments of the bone on the upper fragments, interfering with the union of the parts.

Objection fourth: That the movable foot piece is straight up and down, whereas the natural position of the foot is with the toes turned slightly outward.

Objection fifth: That as the foot settles down towards the foot piece, after being adjusted, the traction ceases until the screws are turned at the next visit of the physician. In using this splint I have been constantly troubled by these objectionable features, and I have therefore attempted to overcome them in the manner illustrated in the accompanying cut.

The first objection is overcome by a plate of iron with a long slot occupying the position of the notches, and another plate of iron, hinged, is screwed to the base of the permanent foot piece. This latter plate is provided with a bolt and thumb-screw, passing through the slot in the first plate, preventing the possibility of the foot piece slipping in any way, and also having the additional advantage of being adjustable at any distance or angle required; in other words, of increasing or diminishing the angle at pleasure with perfect firmness and safety, and no danger whatever of its slipping.

The second objection is overcome by placing the foot piece lower down towards the heel.

The third objection is overcome by fastening the foot piece to a solid bar, two inches in width, and three-quarters of an inch in thickness, which slips through a mortise in the immovable foot piece, entirely prevent-

ing any wobbling of the foot piece. This bar can be fixed in any position by means of the thumb-screw on the side.

The fourth objection is overcome by making the foot piece on the bar adjustable for either the right or left foot, so as to give the foot its natural eversion.

The fifth objection is overcome by allowing the thumb-screw in the side of the permanent foot piece to be loosened, and a weight attached to the bar, and hung over the foot of the bed, keeping up a constant traction, until the surgeon sees fit to fix the movable foot piece by means of the thumb-screw, in any desired position.

GLEDITSCHINE.

BY WILLARD H. MORSE, M.D.,
WESTFIELD, N. J.

BOTANICAL NAME.—*Gleditschia Triacanthos*.

Synonyms:—*G. spinosa*, Marshall, arbustum, 54; *G. meliloba*, Walter, fl. car., 254; *G. macrantha*, Willdenow, Baumz., 164; *G. elegans*, Salisbury, prodr., 323; *Melilobus heterophylla*, Honey locust; black locust; sweet locust; tear-blanket; honey chucks; three-thorned acacia.

BOTANICAL DETAILS.—Natural order of the leguminosæ; genus: *gleditschia*.

FAMILY RELATIONS.—*Prosopis pubescens*; *dalea spinosa*; *eysenhardtia orthocarpa*; *robinia viscosa*, *R. pseudo-acacia*, *R. neo-mexicana*; *olneya tesota*; *piscidia erythrina*; *cladrastis tinctoria*; *sophora secundiflora*, *S. affinis*; *gymnocladus canadensis*, *G. monosperma*; *parkinsonia torreyana*, *P. microphylla*, *P. aculeata*; *cercis canadensis*, *C. reniformis*; *prosopis juliflora*, *P. pubescens*; *leucena glauca*, *L. pulverulenta*; *acacia Wrightii*, *A. Greggii*, *A. Berlandieri*; *lysiloma latisiliqua*; and *pithecolobium unguiscati*.

GENERIC SYNONYMS.—*Prosopis juliflora* is also known as "honey locust"; *robinia pseudo-acacia* as "black locust"; *robinia pseudo-acacia* and *robinia neo-mexicana* as "locust"; and *prosopis juliflora* as "honey shucks."

REMARKS ON RELATIONSHIP.—It is notable that *piscidia erythema* is co-related. *Robinia pseudo-acacia*, and *acacia wrightii seu stenocarpa*, have by some been confounded with *gleditschia triacanthos*; but they are not identical. Linnaeus, Gaertner, and some others have sought to make *gleditschia triacanthos* a variety of *gymnocladus monosperma*; but it has been fully proven that the two are distinct. *Gymnocladus monosperma* has a short pod, containing but one seed, while *gleditschia triacanthos* has a long pod with several seeds. There are four or five of the

gleditschia; but these two are the only American species.

DESCRIPTIVE BOTANY.—Flowers polygamous; calyx short, $\frac{3}{8}$ cleft; lobes divergent; petals and sepals of same number; stamens, $\frac{13}{16}$ distinct, inserted with petals on base of calyx; legume, flat, pulpy; seeds 8 to 15, flat; flowers and pods, both greenish; leaves, pinnate; thorns above the axils, stout, often compound or triple. The pods are generally 8 to 10 inches long, and twisted; the thorns (or spines), average an inch in length; the wood is heavy, hard, coarse-grained, durable, susceptible of high polish, layers marked by open ducts; medullary rays numerous; color, reddish-brown; sp. gr., 0.6740; ash, 0.80. The wood is valued for fence-posts, wagon-hubs, well-curbs, construction, etc. Dr. Porcher informs us that the pods are used, in Georgia, in brewing beer. Children, as well as swine and sheep, eat the pulpy pods, without unpleasant after-effects; but, like the persimmon, they are not considered edible till frost-bitten. Presumably, like the European locust (*ceratonia siliqua*), the pods might be made into a syrup and spirit.

HABITAT.—From western Massachusetts to the Brazos river in Texas, in the Atlantic and Gulf States, on the western slopes of the Alleghanies; west through southern Michigan, to about longitude 96° west: the only section within this area, where it has not been found, is eastern Florida. It is the characteristic tree of the "barrens" of middle Kentucky and Tennessee, and reaches its greatest development in the bottoms of the Ohio and Sangamon. It is quite as common in the dry, sterile hill-country as in the rich and fertile bottoms. In the east, while not indigenous, it has been naturalized so thoroughly as to be accounted an agricultural pest in some sections where it was originally introduced as a shade tree. It grows very rapidly, attaining a height of from twenty-five to forty-five feet.

SUB-VARIETIES.—There are two sub-varieties, viz: *Gleditschia inermis*, which is almost entirely destitute of thorns, and *G. brachycarpus*, which has the thorns and pods abbreviated, and the former white and unbranched. This latter sub-variety is the common wild locust of Mississippi and Louisiana, and is not clearly distinguished from the *acacia farnesiana* and *A. stenocarpa*. The flowers are very inconspicuous. The peculiarity about this form is that on cultivation the pods and flowers are more developed, and the spines become of the color of the

bark, as well as bifid and compound. Another characteristic is its exemption from the attacks of the locust-borer (*cyllene picta*). All trees with spines, even the thorn-apple, growing in the lower Mississippi valley, are locally called "tear-blankets." It is worthy of mention, perhaps, that the *gleditschia brachycarpus* does not afford spines long and strong enough for the Mexican Indians to use as "needles and pins." The leaves of this sub-variety are not deciduous—a fact sufficient to prevent confounding it with the acaciæ.

PARTICULAR MEDICINAL NOMINATION.—While the alkaloid *gleditschine* is afforded by the leaves of the *G. triacanthos* and both of its sub-varieties, it is found in the largest amount in the winter leaves of the *G. brachycarpus*, which is better distinguished by De Candolle as the *G. brachycarpa*.

MEDICINAL PORTION.—The leaves, and the alkaloid derivable from them. The bark of the root is said to be "very active;" but no particular inquiry has been made as to its properties. The pods when eaten are inert; but it is claimed that there are those who are "intoxicated" to some extent by eating them.

CHEMICAL COMPOSITION.—The earliest chemical inquiry related to the pods, the pulp of which was found to abound in albumen. The pod itself is also productive of gluten. As remarked above, it is altogether probable that from the honey-like juice a spirituous liquor is distillable. And it is quite as equally probable that a toxic bitter (?) principle resides in the bark of the root. The leaves contain a peculiar alkaloid, well-termed *gleditschine*, and inappropriately styled "stenocarpine." Seward is authority for the statement that the winter leaves contain $7\frac{1}{2}$ grains to every ten pounds, while the summer leaves contain only 5 grains to the same amount of leaves. My own investigations lead me to believe that it is easy to obtain one grain from every 100,000 grs., and frequently one from 60,000 to 80,000! This applies to the green leaves, the dried leaves responding to analysis "with difficulty." It is yielded up to both water and alcohol, and most freely to the latter. Unfortunately, the alkaloid is not readily crystallizable, but occurs as a semi-liquid mass of a greenish tint. United with acids it forms greenish-white salts, tasteless, and apt to assume the form of four-sided prisms. Possibly the sulphate of *gleditschia* will take the lead in subsequent therapeutical consideration.

Perhaps as good a method of alkaloid determination as any consists in first preparing

an alcoholic extract by the usual course of operation. This is treated with acidulated distilled water at about 110° F., a little animal charcoal being added. After filtration, and partial neutralization with ammonia, a fresh concentrated infusion of galls is slowly added until precipitation ceases. After decanting and washing, this precipitate is rubbed up with about one-fourth its own weight of pulverized litharge. An alcoholic solution is then had, and, after filtration and evaporation, the residue is twice acted on with cold and very pure sulphuric ether, which removes impurities and leaves the *gleditschine*. The action of potassa upon an aqueous infusion of an alcoholic extract of the leaves, will also result in the isolation of the alkaloid, showing that the same result may be had either by crude or elaborate means.

Of the properties of *gleditschine*, I can only say that it is soluble in both cold and hot water, and in ether and volatile oils. It has the peculiarity of frothing on agitation. It is fusible, and combines with several salifiable bases. From the first, I could not obtain as favorable results from my privately-isolated alkaloid as from that of Lehn & Fink, in solution. Indeed, it was all but impossible to obtain any mydriasis from the alkaloid, which I was able to obtain after toilsome laboratory effort. Still in doubt, the following manometric experiments were tried:

1. The effect of atropine on the eye of a curarized rabbit, was a slow depression of the intra-ocular tension.

2. The effect of cocaine was at first a slight elevation of tension, followed by a decrease, less than one-half that of atropine.

3. Lehn & Fink's "*gleditschine*" first largely increased the tension, and then diminished it to an extent less than the increase.

4. A combined atropine-cocaine solution had an effect similar to the "*gleditschine*," except that the after-diminution of tension exceeded the increase.

5. The effect of a compound solution of cocaine, 1 to 5; atropine, 1 to 2; and *gleditschine*, 1 to 2, was the same as that of "*gleditschine*."

6. The effect of my poor alkaloid, "all alone," was, first, great fluctuation in ocular tension, followed by a barely-appreciable depression.

In addition to this, let me add that by atropine, cocaine, and "*gleditschine*," I gain no effect on the corneal curvature, while, from my lonely alkaloid I get a shor-

tening of the curvature, like that from weak pilocarpine or eserine.

Moreover, as above observed, the true alkaloid is apt to crystallize in four-sided prisms, while the "gleditschine" crystallizes in acicular (cocaine-like) form. I cannot understand this, and will only remark that the latter are, if not actually like those of cocaine, very similar to atropine and cocaine, well mixed and shaken together. To my mind, there are two or three alkaloids in the "gleditschine;" at any rate, it is more than equivalent to a two per cent solution.

CONCLUSIONS.—With the leaves of gleditschia tricanthos, I am unable to make such a poultice as Dr. Claiborne nominates. My horses, after wearing the poultice, are as prone to kick as ever when the part is incised. It is told of the editor of a sensational New York daily that when he has a rich, blood-and-thunder article "written up," he directs that it be "located away off down South in some out-of-the-way place." The beauty about locating that poultice in West Feliciana Parish, La., is, that it is an out-of-the-way country of large area, and that by the time its substantiation could be sought out, the bubble might burst.

With the alkaloid, I am unable to obtain any of the results recited by Claiborne, Seward, Jackson, Mitchell, Knapp, or any other. More than this, I am willing to challenge any chemist to procure such substantiation. The results can be procured by "gleditschine," and by a compound solution of atropine-cocaine, with a small quantity of eserine, or of true gleditschine. *They cannot be procured by the true alkaloid.*

I assure Dr. Thompson (*Vide Medical Age*, Oct. 25) that the leaves of this tree (which I have taken so much pains to study) will actually produce an alkaloid; but it is the mountain laboring and bringing forth a mouse. This alkaloid, when obtained, will show certain peculiar properties, but among them the mydriatic and anæsthetic are nil.

HYPNOTISM AND ITS CURATIVE USES.

BY HERMAN B. ALLYN, M.D.,
PHILADELPHIA.

Hypnotism, and the wonderful therapeutic results which have been asserted to follow its employment, have aroused such widespread interest and discussion among Continental physicians, that a breif *résumé* of the subject will probably be of interest to many readers of the REPORTER. Its history is briefly as follows:

In 1840, Braid, of Manchester, England, an enthusiast in animal magnetism, discovered that in most persons on whom he tried the experiment, he could produce a condition of sleep by getting them to look steadily at a fixed object, about a foot distant from their faces and slightly above the level of their eyes. The condition thus developed he called hypnotism. His discovery was a development in the line of animal magnetism, and aroused much interest in England and France. During the early part of the decade from 1850 to 1860, lectures upon hypnotism—then commonly called "biology"—were

frequently given in the various towns and cities of the United States.

In 1860, Liébault, of Nancy, published his book on "Sleep and the Conditions Analogous to It."¹ In this book he maintained that the most essential thing in hypnotism was the suggestion of thoughts to the patient while asleep, and argued that hypnotism was simply a modification of normal sleep in which direction was given to the dreamer's ideas by another person. Liébault's work attracted comparatively little attention until the publication of the book of Bernheim,² which contained new experiments and a keen and thoughtful criticism of the ground previously covered by Liébault.

From this time on experiments with hypnotism became general. The common impression that only hysterical patients can be hypnotized will be seen to be false by the statements of Liébault and Bernheim, that on an average from eighty to ninety per cent. of normal persons are susceptible of hypnotism.

More recently, M. J. Luys, in a communication to the Paris Academy of Medicine, declared that when drugs contained in tubes were hung around the necks of hypnotic subjects, phenomena were often developed representing the physiological action which the drug has when taken internally. For instance, morphia, when applied to the left side of the neck, produced in the patient first a sensation of terror, which deepened into one of anger if the application was prolonged. If, however, the morphia was applied to the right side of the neck, the patient sank down into a chair or on the floor, and wore an expression of calm and comfortable repose, such as is induced by a moderate dose of morphia. Again, when brandy, rum or champagne was applied to the neck, the patient passed through all the well known stages of intoxication, with the symptoms of gradual recovery from it.

M. Luys experimented with eighty-six different substances in this way, and found that they could be divided into two groups, in one of which the patient responds automatically, without speech, to the influence of the drug; and in the other, he passes into a condition of somnambulism, in which he is able to hear and to communicate with those about him. Morphia belongs to the first group and alcohol to the second. Valerian is said to produce such a saddening effect

that the patient goes through the different motions necessary to the digging of a grave and the burial of a very dear friend, even to the religious ceremonies before the cross.

These statements are so amazing that one's powers of belief are for the time hopelessly staggered. It will be no doubt wise to await the report of the committee appointed by the French Academy of Medicine to investigate M. Luy's results, before expressing an opinion as to the accuracy of his observations. It should be stated, nevertheless, that M. Delbœuf has been putting to the test one of the oldest claims in regard to hypnotism, namely, that a magnet will produce trembling and tingling, and at times contractures of muscles, and even cause a contracture to be transferred from one limb to the other. He finds that, whether such results follow or not, depends upon the expectation of the patient. If he thinks he has been given a magnet, the sensations described occur, but not otherwise. Further, it is stated in *Science* that Dr. Voisin has confirmed M. Delbœuf's conclusions, and finds, moreover, on investigating M. Luy's results, that when the utmost care has been exercised in talking to his assistants in the presence of the hypnotized subject, so that the latter may have no inkling as to the physiological effect of the drug, the result of hanging drugs about his neck is negative.

As to the therapeutic uses of hypnotism, they will be readily guessed from the fact that a suggestion to a hypnotized patient is promptly accepted, firmly believed and readily acted upon, and from an understanding of the condition of partial anæsthesia which exists during this condition. The latter was the first to be utilized. A French physician attempted to deliver a pregnant woman, without pain, while she was hypnotized. In this he was only partially successful; for when the labor pains became very severe, chloroform had to be employed. More recently, a surgeon has amputated the cervix for carcinoma, while the patient was hypnotized. The operation seems to have been painless, but it must be remembered that the cervix is not a very sensitive part. Several minor operations have been done with the patient under the influence of hypnotism, such as avulsion of a toe-nail; but it is sufficient merely to mention the fact in order to indicate the practical utility of hypnotism.

In regard to the employment of suggestion to hypnotized subjects for therapeutic purposes, some very striking results have been reported at a meeting of the French

¹ Du Sommeil et des états analogues, etc. Paris et Nancy: 1866.

² De la suggestion et de ses applications à la thérapeutique. Paris: 1886.

Society for the Advancement of Science, at Toulouse, in September last. In the *Deutsche Medizinal-Zeitung*, October 13, 1887, from which paper the information is obtained, Dr. Bernheim, of Nancy, is reported as saying that, in a woman of thirty-five, who suffered from hysterical convulsions and had, in addition, metrorrhagia every eleven or thirteen days, he had been successful by hypnotic suggestion in interrupting this metrorrhagia, and in establishing the regular menstrual period, which then became less painful and exhausting than it had been before. Other physicians who were present reported experiences more or less similar to this one. Hysterical contractures have also been removed by hypnotic suggestion.

One of the most thorough papers, which has yet appeared on this subject, is one by Prof. Aug. Forel,¹ of Zürich, from which some of the information contained in the previous part of this article has been gleaned. After reading Bernheim's book, he was induced to visit Nancy, where he was profoundly impressed by what he saw, and returned from this visit such an enthusiastic convert to the new method, that some allowance must be made for his statements. According to him, the chief therapeutic value of hypnotic suggestion resides in the fact that it continues to exert a powerful influence upon the whole organization of the patient, *after* the sleep is over. Dr. Forel has experimented himself, and reports forty-one cases in which he tried hypnotic suggestions upon others. In fourteen of these cases he failed completely, while the remaining twenty-seven patients were influenced. Among the most remarkable cases which he reports, are six of chronic alcoholism, all of which continued sober and industrious after their dismissal from treatment, though, of course, it could not be told with absolute certainty whether they remained total abstainers or not. One of these patients also suffered from jealousy of his wife, which vanished under hypnotism, and from an old traumatic paresis of his right arm, which yielded to the combined influences of hypnotic suggestion and electricity. Another patient, a physician, in addition to his alcoholism, had twice suffered from acute mania, and had been for years an opium eater, because of severe trigeminal neuralgia. After six weeks of treatment, the patient became a changed man in all respects.

The result of this treatment, in the various

forms of insanity in which Forel employed it, was for the most part without good effect.

But that this method of treatment may be exercised with due precaution, it is well to record the statement made by Dr. Larroque to the Medico-Psychological Society (*N. Y. Medical Abstract*) that in a hysterical girl whom he had hypnotized to cure of vomiting, there remained a contracture of the foot, which persisted some months in spite of suggestions. Dr. Larroque thinks this was the result of the neuro-muscular hyperexcitability, which, during certain stages of hypnotism, is sufficiently great to react to the slightest touch or breath, and so result in contracture.

In conclusion, it may be safely said, that a method of treatment which will cause hysterical dumbness and various forms of hysterical paralysis and even hystero-epilepsy to disappear, is of great service to the specialist in nervous diseases; care should, however, be exercised in its use, and the utmost exertion of medical men should be employed to keep it from being used by base men or for base purposes.

A CASE OF CEREBRAL RHEUMATISM.¹

BY J. B. CARRELL, M.D.,
HATBORO, PA.

On account of the rarity of cerebral rheumatism, I think it worth while to report the following case: During the afternoon of May 10th, this year, I was called to see Miss W., aged about twenty-five years. I found her in bed, suffering much pain in the back and in the articulations of one arm. The temperature was 102°, and the pulse 80. The case was plainly one of acute articular rheumatism, and I prescribed, as anti-rheumatic remedies, salicylate of soda and colchicum, and, to relieve the pain, positive doses of morphia.

The following morning the patient's temperature was the same (102°), and the pulse 90. The severity of the pain was considerably lessened. The same treatment was continued. By the morning of the 12th, all of the joints of the body had become involved, constituting a typical case of acute poly-arthritis rheumatism. The temperature, strange to say, was now one degree lower, being 101°, and the pulse was 96. The joints were much swollen and very painful,

¹ *Correspondenz-Blatt f. Schweizer Aerzte*, August 15, 1887.

¹ Read before the Adjunct Montgomery County Medical Society.

the least motion producing agonizing pain. The amount of morphia was increased, so as to give as much comfort as possible and to secure sleep. The brother of the patient being a physician, was now sent for, and arrived the next day. The temperature was 101° , and the pulse 96, the same as the previous day. There having been but slight action of the bowels, we concluded to take the morphine off for a few hours, so that they might be acted upon. The following medicine was given: $\mathcal{R}$ Sodii salicyl., gr. xx; vin. colch. rad., gtt. xv; tincture digital., gtt. x. Mix. This was given every three hours, alternately, with: $\mathcal{R}$ Hydrarg. chlor. mit., gr. ss; pepsin sacch., gr. iij. Mix. In a few hours the bowels were freely acted upon. Then the calomel was discontinued, and the morphia was given again.

The next morning our patient was more comfortable, being able to move herself a very little. The temperature was 100.5° , and the pulse 84. During the night there had been several loose evacuations from the bowels, and profuse sweating was established. All through the day she was comparatively comfortable, and at my evening visit the temperature was 100° , and the pulse 86.

There being much nausea, and the pulse showing a tendency to weakness, I was obliged to discontinue the anti-rheumatics, and gave four grains of quinine and ten drops of tincture of digitalis alternately every two hours, with morphia and tincture of belladonna. On the morning of the 15th every symptom was favorable; the temperature was 100.5° , and the pulse 84. Throughout the entire day nothing unusual occurred. The next morning I found her much worse. For some unaccountable reason there had been a redevelopment of the disease in a more intense form than before. The temperature was 103° , but the pulse was only 84; the skin was hot and dry; the tongue was heavily coated, and there was a tendency to mental wandering. I prescribed: Extract ipecac., fld., gtt. ss; ext. jaborandi fld., gtt. vi; tr. digital., gtt. xij; every four hours, and one-half grain of morphia as needed to control the pain. During the afternoon the patient became quite delirious. On the next morning I found her temperature 101.5° , and the pulse 90 and full. The delirium had now assumed an active form. Ice was applied to the head, and blisters to the temples. Fifteen grains of salicylate of soda was added to the liquid mixture, and large doses of bromide of potash to the morphia. In the afternoon I found the

symptoms worse. It was with difficulty she was kept in bed. I took off the liquid mixture and gave: Potass. bromid., gr. xx; tinct. aconit. rad., gtt. iij; alternately with morphia. As the disease advanced upon the brain it abated upon the articulations. By the morning of the 18th, nearly all of the marks of inflammation had disappeared from the articulations.

Her delirium was the wildest I have ever seen, it being necessary to keep her under constant guard. The temperature was 102° , and the pulse 110. It was almost impossible now to administer remedies. About the middle of the day she went into coma, and at 6 P. M., after a slight convulsion, died.

It is seldom we see cases of rheumatism in which all the articulations are involved, and the cases are infrequent in which the metastasis is as marked as in this one. Twelve hours after the disease had shifted to the brain, all evidence of articular inflammation had disappeared. At first there was a severe onset, then a remission, then a redevelopment of the disease in a severer form than at first, and finally a shifting of the disease from the articulations to the brain, and finally death.

The first attack was mitigated with positive doses of salicylate of soda and colchicum, aided with free action of the bowels.

Fortunately, cases of the kind just described are very rare, and according to statistics are generally fatal. In conversation with my neighboring physicians, they could not call to mind a similar case in this section. One of my competitors, without seeing the case, said he considered it one of measles.

ADHERENT PLACENTA, WITH HOUR-GLASS CONTRACTION, IN THREE CONSECUTIVE PREGNANCIES.

BY G. B. WOODS, M.D.,
WEST ALEXANDER, PA.

I was called in February 24, 1884, to attend Mrs. C. Bell, in her third accouchement. The child, a well developed female, was born an hour before my arrival. On examination of the mother I found a retained and adherent placenta, with hour-glass contraction of the uterus. I delivered the placenta by the introduction of my right hand, gradually overcoming the contraction of circular fibres of the womb, and detaching the adhered surface of the after-birth. In a short time the patient rallied, and she made a good recovery.

On February 1, 1886, I was again sent for to attend Mrs. B., but, being absent from home, Dr. Wm. Denny attended her. I arrived at the house a short time after the delivery of the placenta, which was adherent, with hour-glass contraction of the uterus.

On October 23, 1887, Mrs. B. was again confined. The child was born an hour before my arrival. I found the patient very much exhausted from hemorrhage, with countenance pale, pulse feeble and fluttering. I proceeded to deliver the placenta as on the first occasion, and accomplished this after some difficulty.

At this date, October 27th, the patient is doing very well.

SOCIETY REPORTS.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, October 24, 1887.

MORRIS J. LEWIS, M.D., in the chair.

Dr. J. T. ESKRIDGE presented a paper on
**Mental and Nervous Diseases as Influenced
by the Climate of Colorado.**

DR. F. X. DERCUM reported

**A Case of Unilateral Convulsions, and Another of Hemiplegia Occurring in
Uræmia.**

The following cases are of interest in connection with the observations of Raymond,¹ and of Chantemesse and Tenneson,² in the same field, and also in connection with two cases of hemichorea, associated with Bright's disease, recently reported by the writer.³ They are as follows:

Case I.—H. S., colored, aged sixty-nine years, an inmate of the Philadelphia Almshouse, had, while in the out wards, occasionally suffered from convulsions. On several occasions he had been admitted into the epileptic ward of the hospital. Here it was noticed that he usually had several convulsions in close succession, each lasting about

five minutes, and that after the attack was over he would fall asleep. His convulsions were always general, and attended with frothing at the mouth.

Mentally he was much impaired. He had delusions of persecution, and sometimes imagined himself unable to walk. He was also at times violent and maniacal during the night, requiring to be strapped in bed.

On August 15, 1887, being much improved, he was, at his own request, again transferred to the out wards.

On August 27, after having had occasional fits for several days, he was again admitted to the epileptic ward. On this day his convulsions seemed much worse than usual. They were almost continuous, and he was brought into the ward in a semi-conscious condition. In striking contrast with the seizures previously observed, the spasms now existed only on the left side, beginning apparently on the left side of the face, extending quickly to the left arm and thence to the left leg, being less severe in the last-mentioned member. During the quiescent periods it was observed that the left arm was paralyzed, as was also to some extent the left leg. The left side of the face was also paralyzed, the mouth was drawn toward the right, and the left cheek was flaccid. The conjunctiva of the right side was sensitive, but that of the left was not. The urine was drawn and examined for albumin, but none detected. The temperature was 97.2°; pulse, 140. The sphincters were relaxed.

After the convulsions had ceased altogether the patient slept. Consciousness had evidently been absent during the attack, but on the following morning, August 28, it had fully returned. The condition of left hemiplegia, however, persisted. His urine was now examined a second time, and revealed both albumin and casts, the latter in large numbers.

On the evening of the 28, the convulsions recurred, the patient having nineteen in rapid succession. On the morning of the 29, he was again conscious, and talked, but during the day he gradually became weaker and died at one o'clock.

An autopsy was held within the following twenty-four hours, and revealed the following: Calvarium of moderate thickness. Dura very adherent, the brain being removed in the calvarium. Pia not thickened, but its meshes very cedematous. Veins of vertex full. Pia presented milky opacities here and there, and was easily separated from the convolutions, a sub pial space having been formed, which was distended

³ F. X. Dercum: "Two Cases of Hemichorea Associated with Bright's Disease," *Journal of Nervous and Mental Diseases*, xiv., August, 1887.

with lymph; vessels of the base of the brain extremely atheromatous. Brain as a whole soft, flattening by its own weight. Ventricles large and excessively pale. Choroid plexuses very pale and cystic. Velum interpositum presented whitish granulations. On section, the cortex was found pale and the white matter excessively œdematous. Serial sections of both hemispheres *failed absolutely* to reveal a focal lesion.

In the general post-mortem nothing of special importance was found except that the *kidneys were markedly granular* and fatty. The lungs were emphysematous, the heart fatty, and the aorta somewhat atheromatous.

Case II.—J. H., eighty-two years old, white, in the out-wards of the Philadelphia Hospital, complained of weakness in the left arm and leg. This continued for four weeks, when he was admitted to the nervous ward of Dr. Mills, temporarily under my care. Here it was noticed that he dragged the left leg a little in walking, and that he moved his left arm with difficulty. Sensation on the affected side was also dulled. The hemiparesis grew gradually more and more pronounced, and was as sharply defined as a hemiplegia of organic origin, which, indeed, it was at first supposed to be. At last, though sluggish mentally, he was able to reply to questions and to make his wants known in his native (German) language. Gradually, however, he failed in mind and body, incontinence of urine, delirium and coma set in, and after having been in the ward two weeks he died. During life the urine had been examined and revealed a small amount of albumin.

On the day following death the autopsy was held, and the following conditions noted: Calvarium and dura normal. The pia arachnoid loose and very œdematous, its meshes milky. Vessels of the base of the brain were very atheromatous. Ventricles excessively pale. Choroid plexuses presented numerous large cysts. The velum interpositum was infiltrated. The brain itself very soft, and on section, found to be œdematous throughout. Careful serial sections *revealed no focal lesion*.

The kidneys were found to be *much contracted and cystic*, markedly cirrhotic.

The other organs revealed nothing of consequence. The lungs presented some adhesions in the right pleura, the heart valves were thickened, the aorta was atheromatous.

Both of the above cases are doubtless to be relegated to affections of the nervous

system occurring during and as a consequence of Bright's disease. Chantemesse and Tenneson¹ have already recorded two instances of unilateral epilepsy occurring in the course of this affection, and have verified one of them by post-mortem examination. Their cases are in everyway a counterpart of the case here reported. The convulsions were strictly limited to one side, and the autopsy revealed merely general œdema of the brain and chronic interstitial nephritis.

The objection may be made that these phenomena of hemiplegia, hemichorea,² and hemi-eclampsia, are due simply to atheroma of the arteries of the brain, by means of which a portion of the cortex or a tract of the internal capsule may receive an imperfect blood supply, be shut off, as it were, from its necessary amount, an oligæmia and œdema being the result. The weight of evidence, however, is against this interpretation. There are absolutely no areas of local softening or local necrosis to be detected, and the œdema is not confined to a spot, but is general, is evenly diffused, and apparently as much in one hemisphere as in the other. Besides, the ingenious experiments of Raymond³ leave no doubt as to the possible one-sided action of the nervous system in uræmia. It will be remembered that he first mutilated the sympathetic system of an animal by removing the superior cervical ganglion of one side. In this way he threw the entire nervous apparatus, so to speak, out of balance. He then ligated the hili of both kidneys, and the convulsions that ensued were limited to one side. He repeated the experiment a second time with the same result. It seems as though the two halves of the nervous system bear unequal powers of resistance and that the weakest yields.

DR. OSLER asked if, at the autopsy, special attention was paid to comparing the two sides of the brain. It was some time since he read the articles to which reference had been made, but his impression was that more œdema had been found on the side of the brain opposite to the side on which the paralysis was present. An interesting point in these cases is that it appears to be absolutely impossible in certain cases to make a satisfactory diagnosis between cases of hemiplegia from apoplexy and cases of hemiplegia from uræmia. He recently went over this question with his class in the case of a man brought into the hospital with hemiplegia,

¹ Loc. cit.

² Dercum, loc. cit.

³ Loc. cit.

unconscious, and with albumin and tubercasts in the urine. He said that it was in all probability a case of hemorrhage, but that it was impossible to exclude positively hemiplegia due to uræmia. He said that it might be a case of œdema of the brain from uræmia, in which the œdema, being more marked on one side of the brain, or from some other cause, the paralysis was unilateral. He had seen one case of unilateral convulsions occurring in a man who was brought into the general hospital at Montreal some eight or nine years ago. He had convulsions for three or four days. At the autopsy in that case nothing was found in the brain that would account for the convulsions. At that time we were not so familiar with œdema of the brain, or with the relation of œdema of the brain in Bright's disease as we are now.

DR. JAMES HENDRIE LLOYD said that Dr. Dercum may recall the fact that, at the meeting of the American Neurological Society two years ago, Dr. Lloyd had referred to a case similar to those just reported. The patient was a boy, aged seventeen years. When he saw him he was in a comatose condition with convulsions, which were confined to the right side of the body. The boy had been a sot, and died a few hours after he saw him. At the autopsy there was nothing found in the brain to account for the condition. The only lesion was the "pig back" kidney. This case was undoubtedly one in which the symptoms resulted from uræmia. He thought that in the intervals between the convulsions it was possible to demonstrate the fact that the side on which the convulsions occurred was paralyzed.

DR. MORRIS J. LEWIS said that a man, aged twenty years, a heavy drinker, under his care, had albumin with granular and oily casts in his urine. He suffered with frequent convulsions, which usually followed the periods of heaviest drinking; and on two occasions the convulsions were most marked on the right side, and were followed by paresis, which lasted two or three days. The young man was placed in a position where he could not obtain alcohol, and has apparently made a complete recovery. There is at present no albumin, no casts, and no paresis.

DR. DERCUM said that, to the best of his recollection, the authors to whom he had referred, have noted no local œdema. He had made three post-mortems in cases of well marked hemi-disease occurring during uræmia, and he had found no more œdema on one side than on the other. The cases

reported by Drs. Lloyd and Lewis are of special interest as occurring in young persons. Most of the cases reported have occurred in old people. With reference to local cerebral manifestations from a general cause like uræmia, he recalled the case of a gentleman under his care for several years, who suffers from chronic contracted kidney. He now and then has general uræmic convulsions. Some years ago he had the following remarkable seizure. He went down town to attend to some business, and while in a bank he suddenly became aphasic. He was perfectly conscious. The aphasia continued for several hours. This looks like another instance of a local manifestation from a general cause.

Mental Affections Associated with Chronic Bright's Disease.

DR. WILLIAM OSLER said that as it was in close connection with the paper of Dr. Dercum, he should like to make some reference to the occurrence of certain mental affections which come in connection with chronic Bright's disease. It is well known that certain mental phenomena occur in connection with chronic renal diseases besides simple uræmic coma. He had reported one case of violent mania in a man aged forty-two years, the subject of Bright's disease. When brought to the hospital, he had been maniacal for three or four days. He subsequently became comatose and died. A very interesting case was recently under his care in the University Hospital. A man was brought to the hospital Thursday evening. He saw him on Saturday. He was then quiet, in a semi-dosing condition, but could be aroused and gave a very intelligent account of himself. The whole clinical picture was that of chronic interstitial nephritis. He thought it not improbable that the man might pass into a condition of coma. There was nothing to attract special attention to his mental condition, and he did not regard his condition as critical. That night he got out of bed in the absence of the attendant, wandered about the ward and finally jumped out of the window. It was subsequently learned that, before admission to the hospital, he had been violent, requiring two or three men to hold him. We were not told this when he was brought to the hospital. He had no doubt that this was an instance of mental disturbance due to chronic nephritis. He was told by one of the physicians who had attended him, that the man was full of delusions. He thought that his wife and others were persecuting him.

He saw another interesting case a year ago last Christmas. This occurred in the practice of Dr. Mullin, of Hamilton, Canada. Here there was also a medico-legal question. It was whether or not the man was in a condition to make a will. There was no doubt as to the existence of chronic Bright's disease. The mental condition was peculiar. He believed that his wife and others had designs upon his life, and it was with difficulty that he could be persuaded to take food. He thought that people were persecuting him. Although he gave a very intelligent account of himself, it was not considered advisable that he should make his will at that time. He was placed upon a somewhat more active treatment than he had previously received. This man subsequently did well, his mind had cleared, and he recovered sufficiently to get about and to make his will.

DR. DERCUM said that the negro, who was the subject of unilateral convulsions, had also presented, at various times, periods of maniacal excitement and had also had delusions of persecution.

PHILADELPHIA CLINICAL SOCIETY.

Stated Meeting, October 28th, 1887.

The Vice-President, DR. MARY E. ALLEN, in the chair.

DR. SOPHIA PRESLEY reported a case of

Rectal Polypus.

Willie C—, a child, six years of age, pale and sallow, who had always been delicate and of a constipated habit, was brought to my office by his mother, who said that he had been suffering from "piles" for about three months; that whenever he had an evacuation from the bowels, there was blood partially covering the stool. This blood caused her to make an examination of the parts, when invariably she found a *fleshy mass* as large as a cherry protruding from the anus. After a short time it would disappear, and not be visible until after the next evacuation.

She had, previously, consulted another physician, who considered the case one of hemorrhoids, and treated it with various ointments, but without any beneficial effect.

I made an examination, but could detect nothing abnormal in appearance, nor by the finger. To help correct the torpidity of the liver, and to overcome the constipation, I ordered:

R Hydrarg. chlor. mitis.....gr. ij
Pulv. ipecac.....gr. ss
Sacch. lact.....gr. xx

M, ft. chart., no. xx.

Sig. One powder to be taken every two hours.

After taking the powders the child was to take a dose of magnesia, and then continue with the following mixture:

R Acid. tartaric.....gr. j
Pepsin (Jensen's).....gr. xxiv
Glycerin.,
Liq. menth., pip.....āā f 3jss

M. Sig.—Teaspoonful after each meal.

To be used locally:

R Unguent. belladon.,
Unguent. acid. tannic.....āā 3ss

M. S.—To be used night and morning in and about the anus.

I requested the mother to return with the child at the expiration of a week. At the appointed time he was brought, with the report that he was brighter and better, generally, but the bleeding still continued; and that the lump appeared at each evacuation, as it had done previously.

As she did not live far away, I asked her to send for me when she again noticed the protrusion. I was called the next morning, and, upon examination, found a purple-red polypus, as large as a cherry, protruding from the anus. Upon making a digital examination I found the growth was attached just above the internal sphincter, on the posterior wall of the rectum, by a pedicle about one-sixth of an inch in diameter.

The following morning I removed the polypus by cutting the pedicle, and to make *perfectly sure* there would be no *bleeding*, I injected about two tablespoonfuls of ext. hæmamelis virginic. fld., diluted with one of water, into the rectum, and ordered more of the mixture to be used in the same way should any bleeding be noticed. The child was to be kept perfectly quiet on the lounge, all day.

I left the house, satisfied that I had performed a successful operation, and had rendered hemorrhage impossible. But when I reached home, after making my other calls, I found that a messenger had been there, two hours before, urging my immediate presence. When I reached my patient he was almost in a state of collapse from loss of blood, but from outward and visible signs the bleeding had ceased.

Soon after I left in the morning the child had an inclination to use the commode, and while seated thereon his extreme pallor frightened the nurse, who quickly laid him on the lounge. About half a teacupful of

blood was discovered in the vessel. His mother immediately injected the hæmamelis, with apparent good effect. Recognizing the grave aspect of the case, I felt the necessity of keeping up the strength of the patient and preventing a recurrence of the hemorrhage, while, at the same time, warding off septic symptoms. This I endeavored to do by administering quinine, in one grain doses, three times a day, giving as nourishment, milk, milk-punch, wine, beef-tea and broths of various kinds.

About the third day his skin presented a jaundiced appearance, and there was distension of the abdomen, without tenderness.

I now saw the importance of freeing the intestines from the accumulated blood and fecal matter; and for that purpose administered a large dose of castor oil, but without effect. I gave him another dose with the same negative result. I then gave an enema of warm sweet oil, which he retained, and an hour later, one of warm water, after which he had a passage of fetid, coagulated blood. For fully three days, these bloody, offensive evacuations continued at frequent intervals. At the expiration of that time the patient showed signs of decided improvement, although the unhealthy appearance of the skin remained.

The vigorous use of proper stimulants, tonics and nourishment, gradually induced a more healthy condition, and in a reasonable length of time he recovered his original strength; and has since (a period of almost three years) shown no symptoms indicating a recurrence of the trouble.

In conclusion, Dr. Presley said:

"Although the operation was successful, in the end, all the accompanying symptoms convinced me, that to have prevented hemorrhage and its attendant consequences, *I should have ligated the pedicle.*

DR. EDWARD E. MONTGOMERY then exhibited a set of O'Dwyer's tubes for Intubation, also those modified by Waxham, of Chicago; and gave an analysis of twenty-five cases on which he had performed the operation.

Of these, twenty-two were seen in consultation with other physicians, many when the chances of a successful operation were impossible.

One of the three cases in Dr. Montgomery's own practice, was the victim of a second attack of croup; the child requiring the tube a second time six months after a previous operation.

All of these cases were successful.

Ten of the twenty-five cases had diphtheria, and six of them recovered. The remaining fifteen who were operated upon, were afflicted with membranous croup, and seven recovered.

The most frequent cause of death was broncho-pneumonia.

The youngest child, to recover, was sixteen months old; the oldest, eight years.

Eleven of these children were under three years of age; six recovered. Of the fourteen over three years, who were operated upon, seven recovered, showing a greater percentage of recoveries in favor of those under three years,—a decided advantage intubation has over tracheotomy, which is considered *less* favorable in persons under three years of age than later.

The shortest time the tube was worn, in a case which recovered, was three days; the longest time was three weeks.

In conclusion, Dr. Montgomery urged the value of this operation, stating as its advantages over tracheotomy:

1. The greater readiness with which parents will give their consent to an operation in which no anæsthetic and blood-letting are necessary, thus gaining valuable time by operating early.

2. The same skilled attention is not necessary, after intubation, as after tracheotomy.

The secretions are apt to become dry and accumulate in the tracheotomy tube, rendering its frequent removal and cleansing imperative.

In intubation the air passing through the mouth keeps the membrane moist, and there is no necessity for the removal of the tube.

—In the *Canada Medical and Surgical Journal*, October, 1887, Dr. Osler says that American physicians are much more pronounced as regards the style of their door-plates and professional cards than English physicians are. He thinks that a large card, say about five inches by three, with gilt and indented edges, and having at the top several specialties and below office hours and telephone number, stamps the man as on the border land, or already in the wastes of quackery. He is charitable enough to believe, however, that some men, particularly young graduates, err in this matter through ignorance, and thinks that medical students should receive, before graduation, a short course of lectures on medical ethics and on the business and legal relations of the doctor. This plan was adopted last year at the University of Pennsylvania.

HOSPITAL NOTES.

LARGE GOITRE.—IMPROVEMENT
UNDER LUGOL'S SOLUTION.

Reported by M. Howard Fussell, M.D., one of the
Physicians to the Medical Dispensary of the
University Hospital.

In September, 1886, the patient, Julia C—, eighteen years old, presented herself at the dispensary, with the following history:

Eight years ago she first noticed a beginning enlargement of the throat, which gradually increased, and was accompanied, until her present visit, with increasing dyspnoea, and failure of strength. There was no family history of goitre, though a younger sister has a very prominent thyroid.

The patient was very anæmic, complained of some palpitation of the heart and dyspnoea, together with difficulty in breathing when lying on her back.

On examination, a huge tumor, which proved to be the enlarged thyroid, filled the *entire interval* between chin and the sternum. On closer examination the tumor was found very tense, pulsating markedly, and there was a distinct thrill and murmur in the left lobe. The isthmus of the thyroid projected as a distinct swelling of the size of an unhulled walnut.

Each carotid was pushed backed entirely out of its normal course. In the left carotid a distinct thrill could be felt and *bruit* heard, both due to pressure. The thrill and *bruit* observed in the tumor were doubtless transmitted from the compressed vessels.

The neck measured *nineteen* inches in circumference. An examination of the heart showed that its action was regular, and that there was no hypertrophy. Over the base of the heart was a soft, blowing murmur. There was no prominence of the eye-balls. The patient was put at once on syr. ferri iodidi and liq. iod. co., 30 drops of the former, and 15 drops of the latter, three times a day.

She has reported at the dispensary at intervals of a month, and says that a gradual improvement has occurred. The distressed breathing first became easier, the anæmia gave place to a natural color of the skin, and dyspnoea gradually disappeared. At her last visit, which was made a few days ago, the following note was made:

The neck measures *seventeen* inches; tumor appears much smaller, is soft to the

touch, while no thrill nor murmurs are to be found either in it or in the compressed carotid. The patient appears in excellent general health, and does not suffer from dyspnoea or palpitation of the heart.

The Lugol's solution was continued.

Cascara Sagrada.

In the *Therapeutic Gazette*, for March, 1887, the writer gave his experience with the above drug in fifty carefully observed cases with the following results:

Of the fifty cases the drug was useful in forty-three (43). It entirely failed in seven (7). In the forty-three favorable cases the dose of the drug was diminished in twenty-nine instances after using it for a longer or shorter time. In *no* instance was it found necessary to *increase* that dose which by trial had been found sufficient to cause a daily evacuation of the bowels.

The fluid extract was the preparation used, in 20 drop doses three times a day.

Continued use of the drug, both in private and dispensary practice, tends to strengthen the writer's opinion as to its value as a laxative in chronic constipation, and enables him to recommend it as a valuable addition to our armamentarium.

Medical Dispensary, University Hospital, November, 18, 1887.

A Monument to Audubon.

At the recent meeting in New York of the American Association for the Advancement of Science, the fact that the remains of the great naturalist, Audubon, lie in an obscure and little visited portion of Trinity Cemetery, New York City, and that his tomb is unmarked by any distinguishing monument, was brought to the attention of the members. At the first autumn meeting of the New York Academy of Sciences, a committee was appointed to solicit funds and make all arrangements for a monument. This committee has organized, with Dr. Britton as secretary and treasurer, and is now ready to receive subscriptions. Checks should be made payable to N. L. Britton, treasurer, and post-office orders should be drawn on Station H, New York city. The committee estimates that between six and ten thousand dollars will be required to erect and engrave a shaft worthy the memory of America's first naturalist, and, while confident that this amount will be forthcoming, desires to have interest taken in the project by scientists in all departments, in all portions of the country.—*Science*, Oct. 28, 1887.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Marvellous Voice.

Most people who have been to the "Wild West" show at Earl's Court must have been struck by the enormous vocal power displayed by Mr. Frank Richmond, the "Orator," who explains the action of the realistic drama so vividly presented by Buffalo Bill's cowboys and redskins. The voice of this modern Stentor is a physiological curiosity in its way, for he has often made himself distinctly heard by an audience of thirty thousand persons in the open air. This throws Mr. Gladstone's famous record at Blackheath in 1874 altogether into the shade. Some idea of the vast amount of work which the "Orator" gets out of his vocal organs may be formed from the fact that his running commentary on the show contains more words than the part of Hamlet, which, as is well known, taxes the powers of the best trained actors. This severe effort the "Orator" makes—and makes successfully—twice a day for months together, under much less favorable acoustic conditions than players even in the largest theatres. A few physical details respecting such a vocal athlete may, therefore, be interesting to some of our readers. For these we are indebted to the courtesy of Dr. Robert C. Myles, of New York, whose examination, it may be added, was confirmed by Sir Morrell Mackenzie. The vocal cords are of ordinary length, and not much above the average in breadth, but the vocal processes at once strike the observer by their extraordinary development. They project inwards towards the middle line like two large spurs when the glottis is open. The great leverage thus given to the laryngeal muscles allows them to act to the best advantage with a minimum of effort. The larynx itself is of a large size, and the pharynx is exceptionally roomy and well developed, whilst the mucous membrane covering it is remarkably free from granulations and roughness of any kind. The "Orator's" vital capacity is not above the ordinary standard, but what breath-power he has he utilizes to the utmost with the art of a trained elocutionist. Mr. Richmond, we believe, was on the stage before he occupied his present position, and the secret of his remarkable delivery lies more in the perfection with which he has learned to use his natural advantages than in any

notable peculiarity of physical conformation.
—*Brit. Med. Journ.*, October 1, 1887.

The Epidemic of Miliary Sweat Rash in France.

On March 16th, of this year, according to the *Lancet*, October 1, 1887, during an epidemic of measles, there appeared a case of *suette miliare* in a young man eighteen years old, living at Sillards, in the canton of Lussac-les-Châteaux. From this first case the disease spread and became epidemic. It was usually preceded by such premonitory symptoms as feverishness, weakness of the legs and general malaise, followed the next night by copious sweating. The nervous symptoms were continued feeling of suffocation, sometimes increased into paroxysms; a sense of epigastric constriction, palpitations, agitation, and delirium. Cramps and contracture of muscles were also observed. The tongue was furred and the bowels constipated. In the first stage cough is habitual, and epistaxis generally abundant. The second period commences with the appearance of the eruption, which consists of two chief features: first, a miliary papule, transformed later into a vesicle, which finally discharges; and, second, a polymorphous erythema, which may be arranged under three forms—a red rash, a measles-like eruption, and a purpura. The measles-like rash appears first, and is followed by the scarlatinal and purpuric forms. The eruption first appears on the face, from which it spreads to the neck, trunk, upper limbs, and finally to the legs. The soft palate is speckled with red; and papules are particularly apt to occur on the forearm and dorsal surface of the hands. *Suette blanche* is composed of papules which remain hard and opaque. Frequently the eruption comes out in successive crops which do not exceed two or three in number. The eruption disappears completely and rapidly, but occasionally the purpuric spots remain a long time. During the eruptive period the fever is less intense, and the stomach derangements and malaise are less pronounced. Constipation, however, continues, and the stools have an offensive odor. The urine is scanty and sometimes suppressed. Copious vomiting of blood has been noted. The eruption is followed by desquamation of the skin, which occurs locally and in large flakes, especially about the fingers and palms of the hands, and which rapidly succeeds the appearance of the eruption. Convalescence is

tedious. The disease affects children chiefly. It is contagious, but there is no evidence of its propagation by water or other ingesta. The period of incubation is said never to exceed twenty-four hours. The mortality of those attacked ranged from twelve to thirty-three per cent. M. Brouardel, who investigated this epidemic at the instance of the French Academy of Medicine, by establishing a cordon around the affected areas, and by disinfecting the clothing, succeeded in checking the progress of the epidemic, which has now practically subsided.

A Mammary Gland in a Dermoid Cyst of the Ovary.

Dr. Desiderius von Velits reports from Tauffer's Clinic in Budapest to *Virchow's Archiv*, a case occurring in a woman forty years old, who had borne twelve children, and in whose ovary on the right side was found a dermoid cyst. In the cyst, besides a mass containing blonde hair, was a mammary gland, corresponding completely in its development to the mamma of a young woman. This occupied the inner surface of the cyst-wall, the latter being 3 mm thick. It was of the size of a child's fist, and from its swollen nipple there exuded on pressure two or three drops of a milky fluid. The areola of the nipple was pale red, and was surrounded by a circle of blonde hair, which was about an inch long.

Histologically, the nipple was rich in nerve and muscle, and the skin, both of nipple and areola, normal. In the nipple was found a very wide sinus, which, as well as the other ducts of the glands, was covered with stratified pavement epithelium. The body of the gland proper was only rudimentary; the normal structure of a rudimentary gland was found more in the deeper parts of the gland.

The author regards this as a case of malformation by excess, and thinks that the case is one of polymastia of the ovaries.—*Deutsche Medizinal-Zeitung*, September 29, 1887.

Detection of Metallic Bodies with the Magnet.

In the *Münchener med. Wochenschrift*, 1887, No. 15, Graser describes the case of a man from whose arm four pieces of a needle had been previously removed, and in which the presence of another piece was suspected. By the use of a strong electro-magnet the location of this piece was discovered, and it was afterward successfully removed through an incision at the spot indicated by the magnet.—*Centralblatt für Chirurgie*, Oct. 8, 1887.

Hemorrhage from the Stomach in Typhoid Fever.

In the *Weiner med. Presse*, No. 13, 1887, M. Weiss reports that a student, twenty-two years old, who, two years before had overcome a moderately severe attack of typhoid fever, was taken sick again with typhoid, which presented pretty violent symptoms. There were severe colicky pains, accompanied by bloody stools and moderately high fever. In the course of the second week, there occurred frequent vomiting and increased sensibility in the epigastric region. After a sudden rise of fever from 100.5°, at six o'clock in the evening, to 105.4° at eight o'clock, there occurred at ten o'clock the vomiting of about $\frac{1}{3}$ liter of a chocolate-colored, acid mass, intermingled with brownish crumbs. Soon afterwards the patient again vomited, this time about $\frac{1}{4}$ liter of black blood; and as a result of frequently repeated hæmatemeses, the patient died on the following morning.

An autopsy was not made, but the author is of opinion that the vomiting of blood was not the result of an accidental complication, but depended upon a typhoid change in the mucous membrane of the stomach. He bases his opinion upon the following argument: A perforating ulcer, or a new formation in the stomach in a condition of ulceration, is, apart from cirrhosis, very properly excluded in a healthy young man who had never had symptoms referable to the stomach, and was not intemperate or syphilitic. Moreover, the so-called hemorrhagic diathesis, which is sometimes present in infectious diseases of a malignant character, did not exist in this case. Finally, the blood could not have come from a section of the colon, which had become glued to the intestine, because the odor of the vomiting was not fecal.—*Centralblatt f. d. med. Wissensch.*, October 8, 1887.

Treatment of Acne.

Lassar recommends, in the *Therapeutische Monatshefte*, 1887, No. 1, the application of Wilson's ointment, prepared as follows:

R	B-naphthol.....	10 parts.
	Sulphur præcipitat.....	50 "
	Vaseline (or lanolin),	
	Saponis virid.	25 "
M.	—Rub gently together to make a paste.	

This ointment is to be smeared on in a layer as thick as the back of a table-knife, and carefully removed, after thirty minutes, with a soft rag. After this the part is to be powdered with talc.—*Centralblatt für Chirurgie*, Oct. 1, 1887.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D., } EDITORS.
CHARLES W. DULLES, M. D., }

All contributions to the Original Department will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium,	6.00
Physician's Daily Pocket Record,	1.25
Reporter and Pocket Record,	6.00
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 10,000 copies.

REMOVING THE OVARIES OF INSANE WOMEN.

A very interesting and suggestive paper on the relation of disorders of the sexual apparatus, or perverted sexual feelings, to mental disturbances in women, appears in *St. Bartholomew's Hospital Reports*, Vol. xxii, from the pen of Dr. T. CLAYE SHAW, of the Middlesex County Lunatic Asylum. In this paper the author propounds more questions than he answers; but the general tendency of his views seems to be that morbid conditions of the sexual apparatus, and morbid sexual manifestations in the insane are to be considered as concomitant with or dependent upon the disorder of the brain, rather than as caused by the physical state of the procreative organs. He appreciates the advantage, in many cases, of investigation of the sexual apparatus in women with

perverted sexual feelings, and the beneficial results which have been obtained in American hospitals for the insane by operative interference in such cases. But, on the whole, Dr. Shaw thinks that the risks of such methods more than counterbalance their advantages to the patient, and his practice and advice is to treat the mental disorder as the cause of the troubles which appear in its course.

From the statement of his experience, we incline to the belief that he might be a little bolder without damage to his main argument. For example, he cites the case of a young married woman who has attacks of mania, coincident with her monthly periods and accompanied by most lascivious demonstrations; while in the intervals between her periods her conduct is perfectly correct. If these attacks continue, he says, dementia must necessarily ensue. And yet, he asks, in regard to this woman: "Would it be right to remove her ovaries?" To this question he gives no positive answer; but we would say, "Undoubtedly, provided the consent of those who are her natural guardians could be obtained." Suppose the operation did not abolish this woman's insane attacks. She would be no worse off without her ovaries, and the frightful risk that she may conceive during one of her free intervals and give birth to a tainted offspring would be averted. Suppose she were to die as a result of the operation. Who would not consider the fact that she happened to be one of the very few who make up the small percentage of deaths, a very questionable misfortune? On the other hand, suppose that she were to be cured of her periodical insanity. What would the loss of her power to procreate be to the gain of sanity! In any of the events supposed, we believe the operation would be justifiable.

More than this, while we have a proper aversion to the idea of mutilation in the abstract, we believe that, in deciding upon the propriety of removing the ovaries of insane women—especially insane married women—the advantage of abolishing the power of procreation deserves careful con-

sideration. Let him, who questions this, watch the progress of insanity in a married woman; see her become pregnant; attend her in her confinement; assume the responsibilities and anxieties of caring for her and her blighted offspring afterwards; and reflect upon the curse which these events impose upon all concerned. All this is within the experience of the writer of this Editorial, and has some influence in shaping his opinion, that the certainty of preventing procreation in insane women, by removing their ovaries, should be regarded as one of the greatest merits of the operation; and that the risk to their lives is an insignificant offset to the possibility that their reason may be restored.

We would not be misunderstood in this matter, or seem to justify recklessness in removing the ovaries in cases of insanity. In what we say we take for granted the exercise of such discretion as a conscientious and competent medical man should use. But we are as thoroughly opposed to the outcry against ovariectomy—made by men, and not supported by women, be it remembered—simply because it is a mutilation, as we are to the temerity of those who would remove the ovaries without due deliberation or for insufficient reasons.

It may be that the zeal of operation has carried some surgeons too far—if so, let their consciences judge them; but there is some risk that purely sentimental objections may hold back good men and skilful practitioners from operative undertakings which would be of the greatest benefit to women themselves and to the human race.

THE BOVINE ORIGIN OF SCARLET FEVER.

In the REPORTER, Aug. 13, 1887, p. 221, we called attention to the fact that Klein had recently made some investigations which seemed to indicate that scarlet fever is communicable through the medium of infected milk. Since then numerous observations in Europe have seemed to warrant the opinion that this disease may have been propagated

from cattle affected with an analogous disease, characterized by the appearance of a pustular eruption upon the teats or udders of cows from which the milk supply was obtained. This matter has attracted more attention on the other side of the Atlantic Ocean than it has in this country; and not a few observers have come to believe that scarlet fever is generally, if not always, propagated from a bovine source.

It would be interesting to have the experience of practitioners in the United States in regard to this matter, especially in the country, where the facilities for investigating the truth of this theory are much greater than they are in the cities; and we call the attention of the readers of the REPORTER to it, because we feel sure that they can make very useful contributions toward deciding whether the cases now being reported with some frequency in England and France are to be considered merely as coincidences, or not.

In a country practice, it ought not to be difficult to ascertain if the cows from which the milk supply of a family is obtained are healthy or are affected with an eruption upon their udders; and a series of cases in which scarlet fever in human beings, and such a disease in the cattle, were found associated would go far toward establishing the theory that scarlet fever is of bovine origin. At the same time, it would indicate a way to diminish the ravages of scarlet fever, the value of which can hardly be estimated.

On the other hand, a series of cases in which no connection could be assumed between scarlet fever and a disease of cattle would set at rest the hypothesis that scarlet fever is usually of bovine origin, and prevent the useless pursuit of an *ignis fatuus* in practice.

In either case a most useful purpose would be served by a well-conducted investigation; and therefore we strongly recommend our readers to avail themselves of the opportunity which many of them enjoy to an unusual degree, to contribute to the settlement of this interesting, but still unsettled question.

THE SEYBERT COMMISSION ON SPIRITUALISM.

We publish in another part of the *REPORTER* some criticisms of Professor Henry Kiddle, under the auspices of the American Spiritualistic Alliance, upon the report of the Seybert Commission of the University of Pennsylvania. Some of these criticisms we regard as well founded; as, for example, that the commission has not yet accomplished what seems to have been contemplated by Mr. Seybert when he made his legacy. On the other hand, we think that its critic has found fault with some of the details of its work which are of a nature unavoidable in any such investigation, and with others which were unavoidable in this particular one. Among the first of these unavoidable details was the selection of some persons outside of the body originally named to conduct the investigation, who by this fact were incorporated into the latter body, which then became responsible for what they did. Another unavoidable detail was the absence of part of the commission from some of the meetings; and no one who is acquainted with the member who attended most of the meetings will suppose that his deafness, to which Prof. Kiddle so pointedly calls attention, by any means prevented him from being an investigator very suitable either to appreciate anything worthy of credence or to discover anything tainted with deception.

The charge of Prof. Kiddle that the commission did not conduct the investigations which they made in a sufficiently serious spirit is, we believe, partly unfounded; and wherein it is true the attitude of the commission was due, not to any unfairness on their part, but to the character of the subject presented to them. We are by no means sure that spiritualism presents no manifestations worthy of serious consideration, or that careful and conscientious study may not lead to the discovery of important relations between disembodied ghosts and mortal men; but, at the risk of being set down as prejudiced, we do not hesitate to say that the manifestations of which we have any knowledge are so contemptible that it seems a waste

of time for men who have any useful occupation to turn aside to consider them.

In conclusion, it is right to say that the Seybert Commission does not regard its work as ended; and that when any spiritualist has evidence to present which is worthy of consideration by men of reasonable and well-balanced minds, it will secure a patient and fair examination by this commission. So far as it has gone, we believe the commission has acted wisely and judged justly. The opinions it has announced are, we believe, those of most scientific men. What it, and all men, shall think in the future depends wholly upon what spiritualists can demonstrate; and until the latter can produce demonstrations very different from those which have been presented hitherto, it will avail little to cry out against the verdict of the great mass of thinking men.

THE TREATMENT OF PNEUMONIA.

A fair experience in the treatment of pneumonia leads us to the opinion that most cases may be conducted to a favorable issue by a method something like the following: If the patient is a strong adult, with a hard, full pulse, venesection from the arm may be very advantageous at the onset of the disease. If the patient is old, or weak, or if the disease has already lasted several days, venesection may be dangerous. When venesection is out of place, supporting remedies must be used. An excellent prescription is composed of five minims of tincture of digitalis, five minims of deodorized tincture of opium, and five minims of aromatic sulphuric acid, with enough tincture of cardamon or lavender to make the whole up to a teaspoonful. This dose may be given every three hours until the frequency and violence of the cough are abated, or until some drowsiness is produced. For persons in adult life, no other stimulant is necessary, as a rule. For old people, the administration of small and frequent doses of whiskey—a teaspoonful every hour—is often of the greatest service.

The local application of large mush poultices, or enveloping the chest in cotton, or fine carded wool, is often comforting and

serviceable. Cupping we have little faith in, although many practitioners, who have used it often, think it of service. In the case of old, weak, or debilitated subjects, we believe it to be dangerous.

If a pneumonia reaches the stage of cyanosis, we would recommend the use of strychnia hypodermically, in doses of $\frac{1}{60}$ to $\frac{1}{30}$ grs., as suggested by Dr. Habershon; although we have had no experience in its use.

It may be scarcely necessary to say that in cases of pneumonia—as of all diseases—it is of the greatest importance to keep the bowels, the kidneys and the skin in good working order. The administration of a prompt, but not violent, cathartic, or of a stimulating enema is often of the greatest service at the outset of a pneumonia. In the later stages a cathartic is rarely demanded. The kidneys may be kept active by the free administration of water, and especially of water combined with nitre. A very good way to accomplish this is to order a teaspoonful of sweet spirits of nitre, to be placed in a tumblerful of water, to which a little lemon-juice may be added, and a tablespoonful of the mixture to be given every hour. This combination has the advantage of acting upon the skin, as well as upon the kidneys, and tends to keep up cutaneous transpiration.

These suggestions cover the main indications in the medicinal treatment of pneumonia, namely, relieving the lungs as much as possible of the work of elimination, lessening pain and irritation, quieting cough, strengthening the heart, and promoting removal of the products of inflammation. For the support of bodily nutrition, attention to feeding is important. Usually not much food is needed, and too much is injurious. The best diet we believe to be one of milk exclusively, given hot or cold as the patient wishes, remembering that when the vitality is low hot milk is to be preferred, and that the digestion of milk is facilitated by adding a little salt to it, ten or twenty grains to a tumblerful.

The method proposed above is not offered as an exclusive one. Different medical men often reach the same goal by different ways.

But this method has given very satisfactory results in the treatment of pneumonia in a large number of cases, many of which were in the persons of aged people, in whom this disease is usually most serious and most apt to be fatal.

SUTURE OF THE URETHRA AFTER LACERATION.

The tendency of modern surgical methods is to attempt to secure immediate union of most wounds by approximation and suture. In many cases such attempts are perfectly rational, and usually crowned with success. In the case of lacerated wounds of the urethra, however, it is by no means clear that immediate closure of the wound gives the best results. The structure of the wall of the urethra, its anatomical relations, and its functions, are such that primary union is hard to secure and not always desirable. At a meeting of the Société de Chirurgie, of Paris, Oct. 26, 1887, M. LUCAS CHAMPONNIERE reported two observations of LOCQUIN, which confirm the statements just made. In one of these cases the attempt to secure immediate union was wholly unsuccessful, and it was necessary afterward to freshen the edges of the opening and reunite the divided canal. In the other, the primary suture accomplished its object; but this was followed some years later by a cicatricial stricture which had to be excised, and a new operation was required to join the separated parts of the urethra.

Justice to the operation of immediate suture requires the admission that the failure may have been due, in these cases, to the way in which, and the circumstances under which, it was performed. If the tissues were much contused, or if the steps of the operation were not carried out with sufficient judgment and skill, the blame of failure cannot attach to the method itself.

The determination what to do in cases of rupture or laceration of the urethra will usually rest upon the conditions which each case presents, and upon the familiarity of the surgeon with the technique of operations upon this part. For uncontused lacerations,

we believe immediate suture should be attempted by any surgeon of fair skill and dexterity; for laceration, with much crushing of the tissues, we think no such attempt should be made. And, if, after a judicious attempt to close a lacerated urethra, union does not take place, we would by no means consider this a contra-indication to the method; nor would we think it just to blame an operation of this kind for a subsequent cicatricial contraction, which might have been much worse if the healing of the laceration had been left to nature.

A CASE OF SO-CALLED HYDROPHOBIA.

In another place, we publish an account of a death from so-called hydrophobia, which occurred recently in New York. It is impossible, of course, to speak with positiveness about a medical matter, on evidence presented by most daily newspapers. But certain points in this case will fix the attention of those who have made a careful study of what is called hydrophobia. First, as usual, there is no evidence that the dog which did the biting was affected with rabies—except the fact of biting several persons, which is not a strange thing for an excited dog to do. Second, there is no evidence that either of the two persons bitten at the same time with the man who died have suffered in consequence. Third, the patient was a drinking man; and intemperance often produces symptoms like those of so-called hydrophobia. Fourth, the account of the case shows that the patient believed he had hydrophobia, and leads to the suspicion that his physicians may have strengthened his belief by what they did or said. Fifth, physical restraint was used and opiates were administered; both of which have a prejudicial effect upon persons in the condition of this unfortunate man.

Taking these facts into consideration, we hope that this case will be made the subject of careful study by those who are familiar with its whole history and all its details; and, until we have further evidence with regard to it, we are disposed to class it with other

cases of pseudo-hydrophobia, caused by the use of alcohol, and shaped by the fear of the patient and the conduct of those about him.

INTERNATIONAL COPYRIGHT.

We publish in another part of the *REPORTER* a statement from the New York *Tribune*, which announces the conclusion of a convention on copyright between Great Britain, Germany, Spain, Switzerland, Tunis and Siberia, which will insure to authors in these countries the rights which they ought to enjoy in all lands. The London *Globe* regrets that the United States is not joined in this convention—and so do we. It is true that American authors probably suffer as much from English piracy as English authors suffer from American. But this fact does not justify the wrong on either side of the water; and we shall use the influence of this journal to dissuade publishing houses in the United States from doing to foreign authors what we consider unjust when done to those of our own country. For we believe that a firm attitude on this subject, by the leading periodicals in England and America, will hasten the day when literary work shall enjoy full legal protection throughout the civilized world.

GLEDITSCHIA.

We publish this week a very complete report, by Dr. Willard H. Morse, upon the vexed subject of gleditschia and gleditschine. This will give our readers an idea of the exact standing of the claims made for this so-called alkaloid. Those who still believe in it have made an attempt to have their process investigated by the Editors of two medical journals in New York, Drs. Shradley and Foster; but as one of the conditions was that the process should not be disclosed, we understand that one of these gentlemen has declined to act as an examiner. The report of Dr. Morse will furnish our readers with information in regard to what gleditschia is and what are its properties, so far as they are now known.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the *REPORTER*.]

LECTURES ON THE DIAGNOSIS OF DISEASES OF THE BRAIN. By W. K. GOWERS, M.D., F.R.S., Professor of Clinical Medicine in University College (London), etc. Second edition. 8vo, pp. vii, 254. Philadelphia: P. Blakiston, Son & Co., 1887. Price, \$2.00.

The first edition of this work was received with great favor by the medical profession, and at once it took its place as one of those which no student of brain-disorders could do without. The second edition contains a correction of certain trifling inaccuracies in the first, and numerous additions suggested by the result of investigations made since its predecessor appeared. The whole is an admirable presentation of the subject of diseases of the brain, chiefly from the standpoint of the physician. It would be hardly fair to criticise the omission of certain features of surgical injuries of the brain; and yet we would be glad if the author would direct his attention to the phenomena resulting from accidental or experimental traumatism of the brain, which have been so thoroughly studied by certain German investigators. It would be especially valuable to have his judgment in regard to the effects produced by injuries to the vaso motor, respiratory, and heat centres, which are of so much importance in determining the diagnosis and the prognosis after blows upon the skull. We would also be glad to have his views upon the effect of increased tension within the sheath of the optic nerve.

Even without these, however, this book is one of the greatest value, and we can most heartily recommend it to our readers.

ANATOMICAL TECHNOLOGY AS APPLIED TO THE DOMESTIC CAT, AN INTRODUCTION TO HUMAN, VETERINARY, AND COMPARATIVE ANATOMY, ETC. By BURT G. WILDER, B.S., M.D., Professor of Physiology, Comparative Anatomy and Zoölogy in Cornell University, etc., and SIMON H. GAGE, B.S., Assistant Professor of Physiology, in Cornell University, etc. Second edition, revised. 8vo, pp. xxvi, 577. New York and Chicago: A. S. Barnes & Co. Price, \$4.50.

This rather long title corresponds with those of many German books and papers, in which an attempt is made to indicate on the first page the scope of the work which follows—a practice which may suit authors, but which is a cause of much distress to reviewers. The book before us is an exceedingly thorough treatise on the method of studying anatomy as applied to the domestic cat. Everything pertaining to this subject is discussed in the most complete manner, from apparently trivial details of conduct in the dissecting room to the reasons for adopting a certain terminology. If the book has a fault, we should say it was in being too complete. The introduction, for example, contains an interesting, but hardly necessary, attempt to justify the methods of teaching which the authors have found successful, and the terms which they have adopted after an experience which—if not peculiar—would be repeated wherever their plan secured a fair trial. As a whole, the book is a monument to the patience and industry of the

authors, and a valuable guide to those for whom it is intended.

TRANSACTIONS OF THE ASSOCIATION OF AMERICAN PHYSICIANS. SECOND SESSION, 1887. 8vo, pp. xx, 254. Philadelphia: Printed for the Association, 1887.

The volume before us contains seventeen interesting and valuable papers on a variety of medical subjects. Among the most interesting are that of Dr. Billings on the "Methods of Research in Medical Literature," that of Dr. Bruen on "Bergeon's Method of Treating Phthisis," and that of Drs. Pepper and Griffiths on the "Treatment of Phthisis by Gaseous Enemata." The first of these papers is written in that attractive style which has made Dr. Billings so agreeable, as well as so instructive an authority on the subject he presented. The other two papers are of great value in themselves, and led to the expression of valuable opinions in the discussion which followed them. The status of Bergeon's method at the present time is clearly indicated in the views expressed by the members of the Association of American Physicians, although some of the hopes which seemed justified when they last met have not been realized.

Much of the contents of this volume of transactions has already appeared in the columns of the medical journals—fortunately for the profession; but we can recommend the whole to our readers as a valuable addition to their libraries.

RECTAL AND ANAL SURGERY. By EDMUND ANDREWS, M.D., L.L.D., Professor of Clinical Surgery in the Chicago Medical College, etc.; and E. WYLLYS ANDREWS, A.M., M.D., Adjunct Professor of Surgery in the Chicago Medical College, etc. Illustrated. Large 8vo, pp. x, 111. Chicago: W. T. Keener, 1887.

This admirable book contains not only a succinct and excellent account of most of the diseases, injuries and malformations of the anus and rectum, and a thoroughly reliable description of the most approved methods of treating them, but also a very interesting summary of the teachings and practices of the "itinerant," or "quack," specialists in these troubles who have so recently and so generally flourished in the West. It is true that the Eastern part of our country has not been, and is not now, free from these persons; but the principal field of their industry has been West of the Alleghany Mountains. The authors, with great discrimination, indicate the reasons for their temporary success and the causes of their eventual failure. This features of the book before us make it almost, if not quite, unique in medical literature, and add much to the value of what, even without it, would be a very valuable book.

A STUDY OF THE HISTOLOGICAL CHARACTERS OF THE PERIOSTEUM AND PERIDENTAL MEMBRANE. By G. V. BLACK, M.D., D.D.S., Professor of Pathology in the Chicago College of Dental Surgery. Large 8vo, pp. ix, 138, with fifteen full page plates. Chicago: W. T. Keener, 1887.

One is apt to run out of adjectives when a series of good or bad books come up for review at one time; so when we wish to express an opinion of the book before us, it is not easy to select those which will be appropriate, without repeating what it has been our pleasant duty to say just before. Dr. Black's essay is a most complete one, and might be taken for an

example of what careful, thorough and ingenious work will produce. We can recommend it heartily to students of dentistry, and of histology, as a mine of information. The plates which illustrate it include 67 original drawings, which reflect equal credit upon the author and upon the publisher. The work of the latter is so good that we pay the book a high compliment when we say that it is as handsome as it is valuable in a scientific sense.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—Mr. Labouchere, Editor of the *London Truth*, says: Mr. Pearsall Smith's suggestion for a copyright treaty with the United States is a most sensible one. Heretofore we have negotiated not so much for our authors as for our publishers. Mr. Smith proposes that we should ask the United States to assent to English authors being allowed a royalty on their works when published in America, with the same reciprocal advantage to American authors here. If this were agreed to, there would be no monopoly. Fifty American publishers might issue a work, and compete with each other in cheap editions, but the English author would get 10 per cent. upon the retail price of every copy sold. This would be payment by results, in its most reasonable form.

—A Convention on Copyright has been signed by the representatives of Great Britain, Germany, Spain, Switzerland, Tunis and Siberia, and will come into force on the 5th of December. It places an author, composer or artist belonging to any one of the countries named in a position of equality, as regards the copyright of his works, with the authors, composers and artists of any of the other countries named. As regards translations, the copyright is to extend over ten years from the completion of the original publication; while in the case of anonymous or pseudonymous works the publisher will be entitled to protect rights belonging to the author. The rule as to books will apply also to periodicals and newspapers for which copyright is claimed; but in the latter instance protection is not accorded to news or to "articles of political discussion."

—The *London Globe* says that "one nationality in particular is conspicuous by its absence from the Convention on Copyright, namely, the United States of America; and until this country is included the Convention can be regarded only as a partial blessing."

—*Littell's Living Age* maintains its usual high standard of selections from foreign periodicals. Just now it is publishing a serial story, entitled "Major Lawrence, F. L. S.," which contains incidentally an interesting description of a patient with phthisis. A short article from the *St. James Gazette*, by Sir Thomas Crawford, maintains that the physical condition of the lower classes in England is deteriorating.

—The Emperor of Brazil is said to be suffering from an advanced stage of diabetes.

CORRESPONDENCE.

Diphtheria.

EDS. MED. AND SURG. REPORTER:

Sirs:—1. Is there a pathological condition that you can in truth call *diphtheritic croup*? Please answer through the REPORTER. I should like to see an editorial on diphtheria and its treatment.

2. Will you tell me the best *treatise* on diphtheria?—at least in your opinion.

3. Have Dr. Formad and his colaborer a work out, on the result of their investigations on diphtheria?

4. If so, can the work be gotten through the office of the REPORTER? Also state price.

The REPORTER is fine. I have been a subscriber for many years. Could not well get along without it. Pardon me for troubling you. Yours truly,

H. E. ZIMMERMAN.

Mt. Jackson, Pa., Nov. 12, 1887.

[As a rule, we cut out of the letters we receive all expressions like "your valuable journal," etc.; but the compliment in the end of this letter seems so hearty that we cannot resist the temptation to let it pass.

To the writer's questions, we reply:

1. No. We regard croup and diphtheria as totally different diseases.

2. We cannot name the best book on diphtheria; but we can strongly recommend our correspondent to get "A Treatise on Diphtheria," by Dr. Abraham Jacobi, of New York.

3. The result of the investigations of Drs. H. C. Wood and H. F. Formad have been published as "Appendix A., Report of the National Board of Health for 1887." We advise our correspondent to apply to a Congressman from his district for it.—EDS. REPORTER.]

Prescription for Lumbago.

EDS. MED. AND SURG. REPORTER:

Sirs:—I see a prescription for lumbago in your REPORTER for May 21, 1887, page 667; also repeated October 22, 1887, page 554.

I have been placed in rather an embarrassing position, as our druggist tells me that the prescription cannot be filled without its precipitating. Very respectfully,

G. G. MORRIS, M.D.

708, 13th St., N. W., Washington, D. C.

[On investigating the prescription referred to—with the help of a competent pharmacist of this city—we find that Burggraeve's formula cannot be prepared without precipitation, owing to the action of the water of

ammonia upon the collodion. But an elegant and perfectly clear preparation results if spirits of ammonia be substituted for the water of ammonia, as follows:

R Tr. iodi,
Collodii,
Spiritus ammoniæ.....āā equal parts.
M. Sig.—Apply with camel's-hair brush.

A clear solution of the same strength results from the combination:

R Aquæ ammoniæ, FFF.....f 3j
Alcohol.....f 3ij

Mix and add

Tr. iodi,
Collodii.....āā f 3iij

This prescription when first prepared is of a dark wine color; after standing 24 hours, it becomes of a pale amber color, owing to decolorization of the tr. iodi.—
EDS. REPORTER.]

A Case of Stricture of the Cardiac Orifice of the Stomach.

EDS. MED. AND SURG. REPORTER:

Sirs:—Having been present at the post-mortem of the late Charles Miller, Dr. Traill Green requested me to write a statement of the case, and send it to you, in answer to your letter to him. I therefore enclose you the history of the case as given me by the widow of the deceased, and an account of the autopsy. The latter was limited to the stomach and vicinity. Mr. Miller was treated by a number of physicians, among whom were Drs. Agnew and Pancoast, of your city.

Case.—Charles Miller, German, aged 51 years, boss carpenter by occupation, had been a sufferer from dyspepsia for about twenty-five years. He was always a very fast eater, wanted his food very hot, and also ate between meals. About eleven years ago he went on a visit to his native country, and returned very much improved in health. From that time on, until the beginning of the spring of 1887, he was able to attend to his occupation. About the 1st of February, 1887, he noticed some difficulty in deglutition. At times the food would enter the stomach, then again it would fill up the œsophagus and be rejected. This condition gradually grew worse, until six weeks before his death (November 1, 1887), when he became unable to swallow any solid food, and could swallow only a small quantity of liquid. His craving for food became ravenous until ten days before he died, when all desire to eat ceased. Rectal alimentation had been resorted to; but to this the patient objected, and it was therefore discontinued.

For ten days before death no nourishment whatever was taken. Thirst became intense, and the patient constantly held ice in his mouth, and let the water run out. He always expressed himself as feeling well, except a choking and burning sensation at the epigastrium.

The autopsy revealed a thick and indurated constriction around the cardiac orifice of the stomach, connected with a large tumor on its left side. The tumor was one inch thick and two inches in diameter. Upon microscopical examination I found it to be an epithelioma. The stricture so completely occluded the orifice that it would not admit of the passage of several grape seeds, which were lodged above it for three weeks. The œsophagus, above the stricture, was very much dilated. The subject was extremely emaciated, and the subcutaneous fat had almost entirely disappeared. There were old pleuritic adhesions on the right side.

Yours truly, A. L. KOTZ, M.D.
Easton, Pa., Nov. 12, 1887.

NOTES AND COMMENTS.

Transient Benign Plaques of the Tongue.

But two cases of this rare disease, which is variously called lingual lichenoid, exfoliatio areatæ linguæ, etc., have been reported in this country. Dr. M. B. Hartzell, of this city, states that he has had the second case under observation at short intervals for two years, and gives a somewhat detailed description of it in the *Medical News*. From a reprint of this paper it is gathered that the patient was a railroad engineer of excellent general health, weighing 175 pounds, who presented, when first examined in June, 1885, an eruption on the tongue which resembled ordinary vesicles as they are seen on mucous membrane. In a day or two this whitish elevation, having increased to the size of a pea, began exfoliating, leaving a circular patch, deprived of epithelium, surrounded by a narrow, slightly elevated white border. After the patch had increased to the size of a dime, it ceased to grow larger, and in a few days the tongue gradually assumed its normal appearance. After an interval of ten to fourteen days, during which the mucous membrane of the tongue seemed perfectly healthy, a new lesion, similar to the first one, appeared, ran the same course, and again disappeared. The eruption required from ten days to two weeks to pass through its various stages. The author

says that the disease has continued to come and go in this manner until the time of the writing of the paper, September 8, 1887. Only one plaque was present at a time, and that occupied the right side of the tongue, never crossing to the smallest extent the median line of the tongue.

Dr. Hartzell believes that the disease is entirely independent of syphilis, and that there is a causal connection between dyspepsia and the occurrence of the plaques. Local treatment seems to be without benefit, but in the case just described, the internal administration of arsenious acid in doses of $\frac{1}{10}$ of a grain, prolonged the intervals between the attacks, while at the same time the individual lesions ran a shorter course.

Death from Supposed Hydrophobia.

A man named Charles Cavanan, died at Chambers-Street Hospital, New York, Nov. 15, from the effects of a dog bite received on Oct. 8. The brain and all the internal organs were congested. The spinal cord appeared normal to the naked eye, which was matter of surprise to the examining surgeons, who expected to find considerable congestion of the cord.

Cavanan saw two dogs fighting in front of his house on Oct. 8. In endeavoring to separate the dogs he was bitten in the hand. Two other persons were also bitten by the same dog, who was supposed to be mad. A policeman shot the animal a few minutes later. Cavanan and the others immediately repaired to Chambers-Street Hospital, where their wounds were cauterized. Those who appeared at the hospital with Cavanan were George H. Neidlinger, 27 years old, and James Cullen, a lad of 15 years. Neidlinger was bitten in the leg, but not severely, the dog's teeth having to contend with his trousers and the leg of an alligator hide boot. He is at present reported as being in perfect health. James Cullen, the boy of 15, was bitten in the hand.

On Monday, Nov. 14, in the afternoon, Cavanan appeared at Chambers-Street Hospital complaining of an inability to swallow, attended by convulsions of the muscles of the throat. He conversed lucidly, but at short intervals he was seized with spasms of the muscles of the throat, accompanied by copious expectoration. He was unable to take liquid of any kind, and remedies for his relief had to be administered hypodermically. Toward the close of the afternoon it was deemed expedient to remove the patient to a private room up stairs. At this

time he was perfectly cognizant of his condition and decidedly frightened. He asked for a priest, and said that he felt that this was a "terrible death to die." At his own request he was placed in a strait-jacket.

During the recurrence of the violent spasms, which seized upon him at intervals, it became necessary to hold him, but when these passed away he was perfectly sane and gentle, even exhibiting a certain grim humor at times. It required a constant effort on the part of the patient to rid himself of the mucus which gathered in his throat, and this effort seemed to occasion him great distress. During the night the patient was seized with violent spasms, so that it was all the attendants could do to hold him down. At 6 o'clock in the morning he fell into a comatose state, and died in half an hour.

The physicians ascribe his death to asphyxia and heart failure caused by convulsions and fixation of the muscles of respiration. Some difference of opinion exists in the hospital as to whether Cavanan was really a victim of the disease known as hydrophobia. It was hinted by an official that the dead man might have exhibited similar symptoms while suffering from an aggravated attack of throat or heart trouble. Others, however, are positive in their assertions that the case was one of hydrophobia.

The Seybert Commission on Spiritualism Criticised.

After a somewhat extended review of the report of the Seybert Commission of the University of Pennsylvania, Prof. Henry Kiddle, says:

"This criticism might be extended much farther, but it is unnecessary. We have already shown that—

"1. There has been no sufficient proper compliance on the part of the Trustees of the University of Pennsylvania with the terms imposed by the founder of the Seybert Chair, and the conditions prescribed by him and agreed to by the University on the acceptance of the fund of \$60,000 bequeathed by Mr. Seybert, on the condition that the 'incumbent of the Chair,' aided or not, as he desired, by a 'Committee of the Faculty,' should make the investigations.

"2. It was a gross violation of these conditions, after the original appointment of five members of the Faculty to act as a Commission, to appoint five additional persons who were not members of the Faculty; and especially to appoint four of

these persons, not connected with the University at all, several months after the investigation had commenced.

"3. The Commission were obligated to investigate the claims of Modern Spiritualism not merely as to its phenomenal basis, but as a system of 'morals, religion, and philosophy;' and this they have not even commenced to do; but have only, in a most unfair, superficial, inconsiderate, and we might almost say irrational, manner, examined the manifestations of a few mediums, whom they have, most unjustly, according to their own record, held up to public scorn and indignation. Under such circumstances, to rush into print with conclusions so lame, imperfect, and ill founded, should subject them to the censure of every impartial and intelligent mind, as we doubt not it eventually will.

"4. They have presented to the public a series of statements, called a report, crude, imperfect, sweepingly condemnatory, and wholly unscientific, neither correctly representing the facts of their own investigation, as a Commission, nor making those distinctions and discriminations as to incidents, principles, and methods which a proper knowledge of the subject would have dictated.

"5. Their report is contradicted in many essential particulars by the minutes of their proceedings, which they have chosen to keep in the background, and away from the general reader, by inserting them in an appendix.

"6. Instead of conducting the investigation by sub-committees, whose carefully constructed reports could have been attested by the signatures of those making them, they have been guilty of the gross impropriety of presenting a report signed by ten persons, which contains statements that only three or four could truthfully attest. In this way they have misled the public, and especially the newspaper press, and given a seeming importance to their investigation and the report which they do not really possess."

William F. Jenks' Prize.

The first award, under the William F. Jenks Prize Fund of The College of Physicians of Philadelphia, will be made by the Committee, for the best essay upon "The Diagnosis and Treatment of Extra-uterine Pregnancy," as soon after January 1st, 1889, as may be practicable. Papers for competition must be written in English, and be presented by the date named. The prize

essay is to become the property of the college.

Blaud's Pills.

The British Pharmaceutical Conference recommended the following unofficial formula for Blaud's Pills:

Sulphate of iron.....	60 grains.
Carbonate of potassium.....	36 "
Sugar, in powder.....	12 "
Tragacanth, in powder.....	4 "
Glycerin.....	2½ minims.
Distilled water.....	2½ "

Reduce the sulphate of iron to fine powder, add the sugar and tragacanth, and mix intimately. Finely powder the carbonate of potassium in another mortar, and thoroughly incorporate with it the glycerin and water. Transfer this to the mortar containing the sulphate of iron, beat thoroughly until the mass becomes green and assumes a soft, pillular consistence, and divide into twenty-four pills.

Each pill contains about 1 grain of ferrous carbonate.

Dose.—1 to 3 pills.

Curious Result of the Cure of Morphinomania.

A very serious paper on morphinomania by Dr. Seymour J. Starkey, in the *Nineteenth Century*, September, 1887, contains one passage which is humorous—or pathetic, we cannot say which. In this the writer says: "I have seen a man become attached and engaged to a girl while addicted to the use of morphia, and place himself under treatment for the purpose of giving up the vice and getting married; but his love vanished with his morphia."

Dangers Attending the Treatment of Obesity.

Professor Rosenfeld (*St. Petersburger med. Wochenschrift*) argues that Vertel's method of treating obesity is not without danger. The deprivation of liquids tends to augment the relative quantity of uric acid excreted, and thereby may provoke parenchymatous nephritis, with albuminuria. Strict supervision is, he thinks, always necessary. Prescriptions relative to mountain climbing and to abstinence from liquids ought to be followed with prudence by persons whose habits have previously been opposed to this regimen: they should cease the treatment immediately upon the appearance of dyspnœa, vertigo, and other symptoms indicative of cardiac incapacity. The attention of the physician ought to be directed to the heart, the stomach, and the urine.—*Druggist's Circular*, November, 1887.

Practical Points About the Urine.

Dr. William B. Canfield, in a paper in the *Maryland Medical Journal*, October 15, 1887, says:

Normal urine may vary in color from a pale yellow to a brownish black, according to its concentration. The color of the urine is a very important factor in the diagnosis at the bedside. A light clear urine (*urina spastica*) would show absence of acute fever and a possible presence of polyuria; while a dark colored urine would denote not only a fever, but might signify a variety of affections of the spleen or liver, a hearty meal, active exercise, etc. Reddish or reddish-brown urine would point to blood, black urine to the presence of the pigment of melanotic cancer (melanuria). Green or brownish-green urine would indicate bile.

Different drugs have a decided effect on the color of the urine; for example, rhubarb (chrysophanic acid), senna and santonin, make it intensely yellow, or a greenish or brownish yellow. Further, logwood, strong coffee, turpentine, carbolic acid, tar, creasote fol. uvæ ursi, kairin and fuchsin, all color the urine. It is not probable that the presence of albumin can be suspected by the color.

The smell of urine may best be described by saying that it is urinous. When concentrated it is strong, when ammoniacally decomposed it is still stronger, and even putrescent. It is affected by certain drugs. Turpentine gives it the odor of violets. The odor of cubebs, copaiba, sandal wood, castoreum, valerian, is imparted to urine after administration by the mouth. Also after eating certain vegetables, such as garlic, asparagus, cauliflower, etc., the urine has a peculiar smell. In diabetes mellitus it may have a sweet smell.

With reference to normal urine, it is always clear when first passed, and it shows on standing a slight cloudiness (nubecula), more noticeable in the urine of women. Microscopically a few epithelial and other cells are always present, and in the case of females, vaginal epithelium. Pathologically the presence of the earthy phosphates of lime and magnesium, of the urates, pus, mucus, blood, etc., causes cloudy urine. Normally urine is aqueous. Pathologically the presence of mucus or pus may cause it to be viscid, and chyle in the urine (chyluria), as observed in the tropics, gives it a turbid and thick appearance. The foam which normally so quickly disappears from urine may remain in the presence of sugar, albumin or blood.

Of Interest to Athletes.

Dr. Sargent, who is well known as the superintendent of physical education at Harvard College, has a very interesting paper in *Scribners' Magazine* on athletics, in which he says that relatively long limbs, with short body, full chest and small bones, will characterize the typical short-distance runner wherever he may be found. Short races (100, 200 and 440 yards) are often won by a few inches, and the value of an inch or two in a runner's stride is of the greatest importance, for, other qualifications being equal, this man is bound to be first at the goal.

The small girth of the legs of runners is often mystifying. From the girth of a muscle one gets a correct idea of its volume or transverse diameters, but learns little of its length and the extent of its contractile fibres; whereas it is the length of the muscle, and not the thickness, which is of significance to short-distance runners. Given the physiological fact that a muscle can contract about one-third of its length, it will readily be seen that the longer the muscle the greater will be the movement of the part to which it is attached. To the runner the desired movement is in the elevation of the thigh and the extension and flexion of the leg and foot. An instantaneous photograph of sprint-runners shows that the range in the movement of the limbs is very extensive—the stride of a fast walker being from 4 to 6 feet, and that of a fast runner from 6 to 8 feet. If the stature is short, it is necessary for the runner to get a greater elevation from the ground at each step in order to maintain a long stride. When this is done a relatively long lower leg is of the greatest advantage. This fact is admirably brought out in the case of Myers, the professional runner. With a height of 5 feet 7½ inches, which is a little below the mean, or 50 per cent. class, he has a length of lower leg which corresponds to a man over 5 feet 10 inches in height, a length of thigh usually found in men of 5 feet 9 inches, while the sitting height is the same as that which makes up the stature of men of 5 feet 4 inches.

—The flexibility of the English language is shown in the reply of an Irishman to a man who sought refuge in his shanty in a heavy shower, and finding it about as wet inside as out, said, "You have quite a pond on the floor."

"Yis; shure we have a great lake in the roof."—*Harper's Magazine*.

HUMOR.

—A circus show can pull more sick boys and girls out of bed than all the doctors in town.

—Scientists say that the savage has a more acute sense of smell than civilized people. When two savages get together, how they must suffer!

—One of the most successful bill collectors of Chicago makes many a difficult collection by pretending to be deaf, and making the delinquent yell his reason for not paying at the top of his voice, so that it is heard by every one in the vicinity.

—Bill Nye makes John L. Sullivan, the pugilist, say: "You will find pale and studious people that knows more about ettykett and the number of bones in the human body than I do, but if a man wants his bones pointed out, and his attention called to 'em, I can do it for him."

—Physician—"Patrick, don't you know better than to have your pig-pen so close to the house?" "An' pny should Oi not, sor?" "It's unhealthy." "Be away wid yer nonsense! Sure the pig has never been sick a day in his life."

—Small Huxleyan—"I say, mammy, dis yer friziology say if a chile hab a narm long 'nuff to reach to de sun w'en he's bawn, he done be dead'n berried sebenty-five year' fo' eber he gwine feel de sco'ch." Mammy (severely)—"An'nias S'phiry Jones, shet dat ar book, 'n' go split de kindlin' 'n' rest my po' brains. 'Pears like's if too much larnin'll make me mad."

—A few months ago the startling announcement was made in the press that a peculiar insect had invaded New Jersey by the million, causing great annoyance to the natives. A German drug journal, wholly unaware, we may assume, of the ironical designation of New Jersey as "Spain," warns the German pharmaceutical public against the probable exportation of Spanish flies by the United States!—*West. Druggist.*

—A Duluth newspaper, telling of the power of the magnetic iron-ore of that vicinity, says that the miners have to wear mocasins, because the ore draws all the tacks from their boots; that houses near the mines have to be built with wooden pins or bolts, because the iron draws the nails; that a wild duck that had inadvertently swallowed a few hairpins was stopped in its flight over the the mines, drawn earthward, and made a

prisoner; and that persons with too much iron in their blood are so magnetized that they sleep in a trance.

Items.

—The Society of Ex-Resident Physicians of the Philadelphia Hospital organized on November 16, 1887, and elected Prof. Alfred Stillé, President. The annual banquet will be held on the first Tuesday of December.

—There were three new cases of yellow-fever at Tampa on November 14, but no deaths. There were 13 cases in the hospital. No new cases of yellow-fever were reported in Tampa, but a case was reported two miles from that place.

—The Hudson river, at Albany, was very low about the middle of November, and typhoid fever was prevalent in that city. Mayor Thacher, at the instance of the Board of Health, issued a proclamation asking all citizens, before using the reservoir water, obtained from the river, to boil it, as it is supposed to contain the germs of the disease.

OBITUARY.

Dr. W. H. Peer, who had lived in Greenpoint, N. Y., for thirty-six years, died on November 13th, at the age of sixty. He had an extensive practice and amassed a fortune, which was profitably invested in real estate. He was ill for ten days with kidney disease.

Dr. Adam C. Hoffner, of Jersey City, on a trip for his health, died November 14th, in Portland, Maine, of paralysis of the heart.

Dr. G. W. Sloane, of Philadelphia, was found dead in McCoy's Hotel, Pittsburg, November 9th. He was accidentally suffocated by gas.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Nov. 13, 1887, to Nov. 19, 1887.

Colonel Glover Perin, Assistant Surgeon-General, retired from active service, Nov. 17, 1887, by operation of law. S. O. 268, A. G. O., Nov. 17, 1887.

Capt. C. B. Byrne, Assistant Surgeon, relieved from temporary duty at Fort McHenry, Md., and will return to his proper station, Washington Barracks, D. C. S. O. 242, Div. Atlantic, Nov. 11, 1887.

First Lieutenant F. V. Walker, Assistant Surgeon, relieved from duty at Post of San Antonio, and assigned to duty at Fort Ringgold, Tex. S. O. 130, Dept. Texas, Nov. 8, 1887.

List of Changes in the Medical Corps of the U. S. Navy, during the week ending Nov. 19, 1887.

Passed Assistant P. M. Rixey, ordered to the Naval Dispensary, Washington, D. C.

CLINICAL LECTURE.

SURGICAL CLINIC.

BY A. G. GERSTER, M.D.,

PROFESSOR OF SURGERY IN THE NEW YORK POLYCLINIC.

Varicocele.

Gentlemen:—The first case to which I would call your attention is one of varicocele, to be operated upon at the German Hospital this afternoon. The patient is about twenty years of age. The varicocele is bilateral; but, as usual, it is more marked on the left side than on the right. There are good anatomical reasons for that, which I need not dwell upon now. I will limit my remarks to some of the methods employed in the treatment of this affection. Formerly, as you must know, varicocele was considered an *opprobrium chirurgicorum*. While some surgeons were devising new methods of cure, others were condemning all methods because they involved great risk. By great risk I mean the risk of pyogenic infection, or a suppurative inflammation. In varicocele there is a bunch of veins, in a distended condition, arranged about the cord in the scrotum, belonging to the pampiniform plexus. In these veins, as in all veins affected with suppurative inflammation, thrombi form; and these thrombi, being invaded by pyogenic organization, decompose. Portions may become detached, and may be carried into the general circulation, perhaps become lodged in the lungs and form pulmonary abscesses. The older surgeons warned against all operations for

varicocele, because pyæmia was so very frequently observed after such operations. Nevertheless, it must be said that some of the surgeons had very good results, even in those older times. They could not understand this difference in results: why it was that all the patients of one surgeon had suppuration and became dangerously ill, many even losing their lives, from an attempt to cure an affection which is not dangerous to life at all; and why the patients, or very many of them, operated upon by other surgeons recovered with little trouble. The reason for this difference in results can now be readily accounted for: it is that the successful surgeons were cleanly, the unsuccessful ones were filthy, in their manipulations. In those days they said, "This man is an unlucky surgeon; that one a lucky surgeon." For they both operated skillfully, and apparently on the same principles in the same manner. Yet the results were very different.

Now the operation for varicocele is known to be proper, to be justifiable. If the case is a mild one, a mild operation is appropriate; and a good procedure is that proposed by our fellow-townsmen, Dr. Keyes: namely, subcutaneous ligation of a portion of the veins returning from the testes. It is a very simple operation, which can readily be carried out in your office with local anæsthesia. This procedure may be adopted on the right side in this case; while on the left side, where the affection is a good deal more extensive, it would not be sufficient. There we will have to do more: we will have to lay open the plexus of veins, and dissect out those which are not essential to nutrition. This is done after first putting on a

double ligature, the veins between the ligatures being excised. Just enough are left to carry away the venous blood from the testicle and epididymis. If we did not leave at least one or two of those veins, the result would be that the artery supplying the testicle with blood would continue to carry blood to that organ, but there would be no chance for it to return. There would be engorgement, œdema, passive hyperæmia, and, as a result of that, we might look forward to two possibilities. The one being that through some small branch veins incomplete collateral circulation would be established. In that case the venous engorgement would not be so great. Most of the blood would remain; but a portion of it would be eliminated, returned to the general circulation by this rather insufficient collateral circulation.

As a result of this want of balance between the arterial supply and the venous reflux, we would see, as we always see under similar circumstances: first, hyperæmia; then hypertrophy,—consisting principally of an increase of the connective-tissue elements. Afterwards these elements would become atrophied, contracted, and would smother that which constitutes the essential characteristic of the testicle: the glandular structure. Therefore, as a consequence of a badly-performed operation, there would be gradual atrophy and shrinking away of the testicle, and you would have robbed the man of one-half of his generative power. If the veins leading from the testicle should all be excised, and the venous return be entirely destroyed, there would be rapid necrosis of the organ. That, of course, would be a great deal more serious than the result just spoken of as following almost complete interruption of the venous return; the patient would attribute the result directly to the operation. But when the testicle gradually atrophies and shrinks away, the patient notices it less; very frequently he does not know that that testicle is not able to perform its function, for he has another one which answers the purpose of the two. But when necrosis takes place, the patient looks upon it as a very serious matter. Still, atrophy of both testicles is a very serious matter. One, who had been operated upon by a renowned French surgeon with that result, felt so grieved by it that he waylaid the surgeon and killed him. Let that example serve you as a warning. Last year necrosis of the testicle followed one of my operations for varicocele. The patient was a baker, and bakers, I may here state,

are very prone to varicocele. It is perhaps due to their standing and unhygienic occupation. They sleep part of the day, and work all night in a heavy atmosphere. They may drink hard, and live as men should not live. As a consequence, we find them anæmic, ill-nourished, and when they acquire a disease, it remains with them longer than it would with a well nourished man who leads a hygienic life.

My patient had varicocele in a very marked degree, and I proposed treatment by excision. I found it very difficult in that case to decide what veins should be removed and what ones should remain. I thought I had left a sufficient number (three or four small trunks) to carry away the venous blood from the testicle. The antiseptic measures observed must have been defective; for, although we had no suppuration proper, yet there was a good deal of infiltration and inflammation of the parts, with slight elevation of temperature—conditions which we usually do not see after antiseptic operations. These lapses from perfect antisepsis are liable to occur to everybody; and I therefore warn you, young men, those who are commencing to work antiseptically, not to boast with your antiseptics. Be conscientious in carrying them out, but never be too sure that you have succeeded; never promise your patient that the wound will surely heal without trouble; especially, be not too harsh in your judgment of the work of other surgeons, for if you are, your next case, in which you think you have followed antiseptic rules in the most exact way, may be followed by suppuration and prove conclusively that your antisepsis had been imperfect. We should not carry our heads too high. Let us do our duty, but never think we are infallible. In the case of which I am speaking, thrombosis of some of the veins occurred, which interfered with the reflux of the blood from the testicle and epididymis, and the testicle necrosed. The first change of dressing was made, I believe, on the seventh day after the operation; we were led to suspect that something was wrong from an elevation of the temperature, and what we found was a yellowish, necrosed testicle. The man was afterward discharged cured, without that testicle.

I may mention as a historical fact that the operation for varicocele is one of the oldest. The Latin, Greek and Indian writers mention the treatment of the affection. The Eastern writers mention it, but they operated in a very radical way. They simply cut off the man's scrotum with the testicle, and that disposed of the whole business.

This afternoon, I shall demonstrate to you two methods. The first, Keyes' method, as I have said, is a very easy one, and can be done, allowing the patient to visit you at your office. The second method is graver, and is performed, in the manner which I have just described, by cutting down upon the enlarged veins where they return from the epididymis, tying them with a double ligature, and dissecting out all but a few branches, which are left to carry away the venous blood. The result of this operation is good. This method is supplemented by partial amputation of the scrotum when that structure has become very redundant and relaxed. As you know, the scrotum is very redundant in its normal state, and a large portion of it may be removed without danger to the patient from shrinkage of the tissues. Some authors think that removal of part of the scrotal integument is in itself sufficient to effect a cure of the varicocele, and that method has been recommended for the cure of these patients. But the results of the operation have not been favorable. When I was a student, I saw cases treated in this manner, but as soon as the initial density of the cicatrix, the tenacity of the newly-formed cicatricial tissue was gone, it became stretched, and the varicocele became worse than before the operation.

Commencing Hip-Joint Disease.

Here is a little girl brought to us by her father for a diagnosis. Before entering upon the history of the case you should always glance the patient over, and make an estimate of her general condition. You observe that she has rather a pale, anæmic integument, covering rather a good supply of flabby fat. The mucous membranes are pale; there is a slight amount of blepharitis; the nostrils are a little reddened. Examining the surface on the legs, we see a number of little eruptions, indicating the presence of eczéma; in short, we have to deal with a child which is anæmic, which has the so-called lymphatic habit. Her father tells me she has never had sore throat; nevertheless the cervical, sub-maxillary, and posterior cervical glands are intumescent. Her general condition is a characteristic one.

Her father tells us that five days ago she sustained a fall on the floor, since which time she limps. Watch the child walk. Her gate is limping, which circumstance may indicate incipient disease. Those doctors who handle horses a good deal, acquire a skill enabling them at once to tell whether or not a horse is lame. This skill may aid them to

tell on which leg a patient limps. The principle is the same. A lame person rests as short a time as possible upon a diseased limb when walking, and throws his weight more heavily upon the sound limb. By observing this child's walk carefully, you will see that it limps on the right limb. You may be able to determine this point only after seeing the patient walk three or four times, dressed and undressed. You should hesitate to say in a case, with apparently very slight symptoms, that the child has not hip-joint disease. That is a point which often baffles the diagnostic skill of young practitioners. They pronounce quickly that the disease is absent, when older practitioners would be more wary and reserved. It is human nature to tell people what they want to hear. A case is brought to him in which the diagnosis of hip-joint disease has been made; the parents are anxious, but they do not believe that the diagnosis is correct. It is only poor people, they think, who have hip-joint disease. Of course nothing will sound better to them than to hear from the young doctor, who has graduated with honors, and has travelled through Germany and other foreign countries, who knows how to handle the microscope, etc., "all nonsense; this child has not hip disease." But the truth is bound to come out. After a time the hip-joint disease makes itself only too manifest, and then the young physician rues his mistake.

We have seen that this child in walking has to limp. Now let us determine where the cause of that limping is located; whether in the tarsus, in the ankle, the knee, or the hip joint. The father of the patient tells us that she has been lame only five days, at which time she sustained a fall. But not infrequently we are able to bring out the fact that the patient had limped a longer time than that given by the parents, and that she had had a previous fall. Sayre says that hip-joint disease is always caused by traumatism. There is no doubt that traumatism has a good deal to do with the development of not only hip-joint disease, but of any joint disease belonging to the group of tuberculous complaints. But, gentlemen, very frequently the traumatism is a consequence of the tubercular joint disease. Not always. Very frequently when there is a tubercular condition in a joint disabling it to a certain extent, the child falls, this resulting in apparent injury to that joint. Let me call your attention to the fact that the bronchial glands are most commonly the primary seat of tuberculosis in children. Tuberculosis of the bronchial glands most frequently appears after an

attack of measles. Old practitioners will tell you that the foundation for a so-called lymphatic habit is ordinarily laid down after an attack of measles. The little patients languish, remain anæmic and puny, and are very prone to chronic joint trouble. Now, if such a child in such a condition falls and strikes upon the elbow, an extravasation will take place in the injured bone adjoining the elbow. That extravasation furnishes an excellent bed for the bacillus tuberculosis; it will settle there and propagate. Then there follows the development of a cheesy focus. Yet the child may be able to play about with its companions and manifest no symptoms further than some stiffness in the morning of the affected joint. It has no fever. The complexion is pale, it is true, but that is common in city children. It takes a skillful eye to detect slight intumescence of the joint. But another traumatism takes place when there is intervening between the cheesy focus and interior of the joint only a very thin lamella of bone and cartilage. The result of the fall is that the thin lamella or bone is broken through, cheesy matter enters the joint, swelling takes place, the child's temperature rises, the doctor is called in and finds acute joint trouble. He diagnoses traumatic synovitis, recommends the usual treatment for that affection, and predicts rapid improvement. We know that the joint of a healthy person, of a healthy child especially, although contused with great force, will recover in a fortnight under proper treatment. But in the class of cases under consideration it will not recover as rapidly. Although the doctor had predicted that the child would soon recover, it will not. The swelling due to serous effusion may in part disappear, but the joint remains thickened; it does not shrink back to its normal size and contour, as it would do in simple traumatic effusion. On examining such a joint carefully you will find there is present swelling, intumescence of the capsule, and frequently not only of the capsule, but also of the subcutaneous connective tissue; in fact all the soft parts surrounding the joint are imbued with a peculiar gelatinous material. This is frequently verified on the operating table.

In inspecting cases of joint disease, it is necessary to observe the external contour, the disposition of the soft parts. It will not do to expose the joint of one limb alone. It is very necessary to compare the affected with the sound limb.

Most of the signs of hip-joint disease have not yet developed, or, rather, are absent in this case. There is absence of flexion of the

high region of the pelvis; difference in the size of the nates is also absent in this case. When there is great intumescence and a large amount of gelatinous material in the joint, the whole gluteal region on the affected side is raised. On palpation, in such a case, you will notice distinct swelling and thickening, and by making deep pressure between the great trochanter and head of the femur the patient will give evidence of pain.

First examine the ankle joint. It is better to assume that we do not know the source of the lameness, and examine all the joints in succession, beginning with the ankle. Having noticed the contour of the joint, we then flex, extend, rotate inward, then rotate outward. Do the same with the knee. Both ankle and knee are normal. Having proceeded upward to the hip-joint, we there make a strong flexion upon the pelvis, and then rotation outward. Having gone through with the examination on one side, and found nothing abnormal, we proceed to examine the other.

Occasionally, I have found in hip-joint disease all movements of the joint free to a certain extent, excepting perhaps one. Rotation in one direction may be impeded, or all the movements be free excepting abduction. In this case there is little impediment to motion until we come to abduction during flexion; there the pelvis follows the limb most distinctly, a great deal more so than on the other side, where in fact it does not follow the limb at all. In rotation also the pelvis follows to some extent. Now we will try the most important test, that is, flexion, and at the same time abduction or rotation outward. The pelvis follows. We can move the entire body in attempting to flex and abduct the left thigh. The question of whether the thigh is permanently flexed is determined by placing the patient flat upon her back and attempting to press the limb down upon the table, in the position of extension. The thigh being flexed upon the pelvis, any attempt to bring it in line with the table will raise the pelvis, leaving a space between it and the table through which one is able to thrust his hand. That is the case in this instance. In fact this patient's symptoms do not justify the assumption of the presence of hip-joint disease. However, we cannot certainly exclude disease of the hip-joint; hence we must say to the parents, if you do not take good care of the child it possibly may develop hip-joint disease. In such cases we have to be most chary and circumspect in prognosis. We will advise the

father to keep the child at rest, and if possible we will practice fixation of the affected limb. After a week or ten days we will examine her again. No harm can be done to the patient by rest and fixation, even if no hip-disease be present. Should, on the other hand, this case be one of beginning hip-trouble, the symptoms of the affection will not fail to appear in time in spite of the treatment, and we shall have the pleasant consciousness of having guarded the interests of our patient.

Lacerated Wound of the Thumb.

We have here a case which would perhaps be looked upon by most of you as a trivial one, but it is not trivial. We have before us a young man of good looks and bright future. You smile, and probably deem my remarks irrelevant. But the consideration of what I said is a part of the true physician's business. I wish to illustrate a point which medical men so often disregard. Here is a young laborer, who depends upon his handiwork, so far as his future is concerned. He has sustained an injury of the thumb. You know that the thumb is the most important of all the fingers. I would rather lose these four fingers than my thumb. Now, if this little wound, which is superficial, which is not very serious, is attended to properly it will heal within a fortnight, and this young fellow will be able to pursue his vocation, to earn his bread, and if he is frugal and ambitious, to save something and rear a happy family. He will be a useful man in our growing country. But suppose that hand is not treated properly? Suppose he should fall into the hands of a druggist who practices medicine, or comes to a doctor, who, although he has a diploma, is also a quack (for there are such); there is considerable hemorrhage, the patient and his friends are scared, the doctor or druggist gets excited, and instead of placing a finger and making pressure upon the bleeding artery, that the hemorrhage may stop; or by ligating the vessel, if pressure be insufficient; instead of doing this, he reaches for the styptic bottle, puts a wad of cotton, soaked in the styptic, on the wound, then covers it with adhesive plaster and a bandage, sends the man home, tells him to come to-morrow and be sure to bring the fee. Now, what takes place? This laborer has injured his hand with a dirty tool. He may be a butcher, and was using a knife which had some filth upon it that was deposited in the wound. The quack has hermetically occluded the wound by applying his styptic. The next day

the patient feels sick; he feels chilly; he has lost his appetite; he has a headache; his bowels are constipated; at night he cannot sleep because his finger is throbbing with pain. Now, if you dress that wound, and succeed in pulling off the mixture of crust, styptic, cotton and adhesive plaster, you will observe that the region of the wound is inflamed and that pus is oozing from it. If the laceration has reached down to the synovial sheath, you will have a lively time with that patient, and the poor patient will have the liveliest time of all. You know that suppuration on the thumb and little finger is worse than if located on any of the other fingers. Celsus and the oldest medical writers, mention the fact, and the common people know that an injury to the thumb or little finger is more serious than an injury to either of the other three. This is accounted for by the anatomy of the parts. The synovial sheath of the three middle fingers consists of two compartments. The one commences at about the middle of the terminal phalanx and extends to the head of the corresponding metacarpal bone. There it ends in a blind sac. From there, the sinew passes through loose connective tissue, and has not a sheath proper for a distance of a quarter to half an inch. Then it enters the common bursa, situated under the palmar aponeurosis, through which all the flexors of the fingers run. Therefore, when suppuration takes place on the three middle fingers, very frequently it perforates spontaneously at a point corresponding to the metacarpo-phalangeal joints where these synovial sacs end. But in the case of the little finger and thumb, the inflammation generally behaves in a different manner. Often we see it jump, as it were, from the finger up to the forearm, and it is for that reason that inflammations of the thumb and little finger have a bad reputation. This is due to the fact that the synovial sheath of the thumb and little finger, although the latter furnishes exceptions, openly communicate with the palmar bursa, which again communicate with the sheaths of the tendons running up the forearm. Therefore, suppuration of the little finger and thumb should be dreaded, and trifling injuries of them be treated with the greatest care. Deep-seated suppuration here may lead not only to loss of the thumb or little finger, but to loss of the arm, and perhaps the life of the patient. Having spoken of the improper treatment of such a case, let us now consider its proper treatment.

You see this man's hand is dirty, as a workman's hand must be. The first thing to be done is to soak it in soap and water,

scrub it thoroughly, and render it clean. Having cleansed the hand, irrigated the wound, and turned out the clots, the question of closing the wound will arise. Is it better to close the wound and seek to secure primary union, or is it better to leave it open to heal in another way? This question is a very important one, and is not always easy to decide. There may be only a small puncture through the skin, but a big gap inside filled with blood clot and filth carried in by a blunt instrument,—such a condition as is frequently seen in compound fractures of bones; fractures accompanied by only a small perforation. A patient, for instance, has been found at the side of the road, lying in the dirt. A kind passer-by sees the distorted limb, and finds a small spiculum of bone projecting through the integument. The limb has been crushed, twisted out of place, is lying in the dirt, and this kind passer-by seeing that something is wrong with the limb, takes hold of it and straightens it, puts it into the straight position. But what has this good Samaritan done? He has replaced that soiled, muddy bone which was sticking out through the integument. Now, that was a poor service. If the bone had first been cleansed and disinfected, and then jerked back into place, it would have been all right. But it was jerked back too soon, that is, it was replaced with all the filth adhering to it. The same thing often happens with small wounds, and suppuration follows inevitably. To avoid suppuration they must be cleansed thoroughly before they are closed, or, if they are to be treated as open wounds, before the dressing is applied. The old time surgeons had, as a rule, better results from severe comminuted fractures, complicated with a large external wound, than from compound fractures with a small external wound. The reason now appears plain; in the first class of cases, to be sure, filth entered the wound, but drainage through the extensive aperture was ample, and the cases often did well. In the latter cases, the small external wound was inadequate for drainage, and if some filth had entered the wound, the destruction wrought by suppuration was appalling. In the former cases there generally is free and ample drainage; in the latter the infectious discharges are retained in the wound, as the small cutaneous wound proved insufficient for drainage. In either class of cases it is of the utmost importance to establish cleanliness, and then, if the larger wound is found too large, it may be partly closed by suture; and, if the small aperture of the integument is inadequate for drainage, that

opening should be enlarged, and supplemented by counter-incisions.

Believe me, it is a great mistake to imagine that a small wound will get well without all that “fuss and feathers,” as anti-sepsis or cleanliness is contemptuously called by some. Some of them, it is true, will get well without attention. But most of them will suppurate and may end seriously. The correct treatment of small wounds is the school wherein to learn to treat correctly larger wounds. If you make a mistake in the treatment of a small wound it may not cost your patient his life, but if the mistake leads to the loss of a limb, it may cost you your reputation.

We find, after thoroughly cleansing the wound on this man's thumb, that it extended just to the sheath of the tendon, but not through it. Now, if we can prevent suppuration, we will have done the man a great service. If we do not adopt measures to prevent suppuration we shall have done him a great harm. To prevent suppuration is the shibboleth of modern surgery.

When, as in this case, the external wound is ample, thorough cleansing and disinfection of the same is easily accomplished. When the wound in the integument is small, and leads to a cavity, it is necessary to enlarge the wound orifice in order to be able to remove dirt or other foreign substances, and to properly disinfect it by mopping out and irrigation. A dressing, consisting of iodoformized and corrosive sublimate gauze is bandaged on the injured part, and now a favorable course of healing may be confidently expected.

White Swelling of the Knee.

Here is a man, aged 32, given to drink, who has come to us on account of a swelling of the left knee. He has the indications of being ill-nourished. He tells us that he once had swelling of one elbow, which he thought was rheumatic, but it festered, and he finally lost the arm by amputation. Now, without any reason known to him, a similar condition is making its appearance at the knee.

What do we notice? First, there is disability to completely straighten and flex the limb. To the hand the left knee feels warmer than the right. The contour of the left knee differs from that of the right. You notice a depression of the patella between two lateral protuberances, which feel doughy, almost fluctuating. The whole joint is intumescent. On palpating it, and after puncture, we find absence of liquid. The phenomenon known

as "ballottement" on pressure over the patella is not noticeable in this case. When the patella is floating a click is produced when it is pressed upon, due to its striking against the underlying condyles of the femur. The general intumescence about the joint would mislead some into the supposition that it was filled with fluid. The essence of this intumescence is to be sought in the thickening of the entire capsule of the joint; a gelatinous imbibition is present, which gives the appearance of fluctuation from liquid. But if we introduce the aspirator we do not succeed in bringing forth any fluid.

You tell me the diagnosis is tubercular osteitis of the knee-joint. I would accept the diagnosis with one qualification. I do not know positively whether osteitis be present or not. My reason for not feeling absolutely certain on this point is the fact that in grown persons tubercular affections of the knee-joint rarely commence in the bone. The common beginning of this trouble is in the synovial capsule. From there, of course, it often extends to the bone, and on opening the joint we find the cartilage destroyed and the bone invaded.

In former times these cases were called the *crux chirurgicorum*—the cross of the surgeon. White swelling was known to be a most intractable complaint, which often led to extensive destruction of the affected joint, necessitating amputation. Local applications, fixation, counter irritants, were all more or less ineffective. Our knowledge of the pathology of this complaint has led to the development of a rational therapy. If the case were that of a child, you would at once see that proper hygienic regulations were carried out; you would see that the joint was put at rest, but in such a way that the patient could take at least a moderate amount of exercise. For this purpose you would apply Taylor's or Sayre's apparatus in the manner so admirably demonstrated at his clinic by Professor Gibney. But in the case of a grown man we cannot procure apparatus which will support his weight any great length of time; and the cases which come to dispensaries are unable to bear the expense of frequent repair and renewal. If made strong enough to sustain weight and wear well, the patient will object to its cumbrousness. Orthopædic treatment is out of the question for many other reasons, among which is the fact that the patient cannot be idle, nor can he gain admittance to a hospital for a term of a year or two years.

Formerly, if the patient would consent

to it, the surgeon put the limb up in plaster-of-Paris, or some other form of apparatus, and kept it confined. The limb had to be spared as much as possible. Perhaps in a year or two ankylosis did result, and the patient was cured at the loss of mobility in the joint. When he could not afford to keep the limb in plaster-of-Paris or some apparatus, but went about as well as he could, using the limb and trying to earn his bread, often cold abscesses formed and fistulous openings leading into the joint established themselves. In such cases the older surgeons took the knife and cut off the limb. That course of things we see has been illustrated in this patient's arm. But at present we do not amputate unless the suppuration, the formation of fistula and destruction of bone, but especially of the soft parts, has gone very far. In cases like the one before us, with tuberculosis of the knee, we do not amputate—we excise the joint. The results in grown subjects are very good. Exsection of the knee-joint before the formation of fistula gives the patient infinitely better chances than when the operation is postponed until after the formation of fistula. So, in cases of this kind, the patient belonging to the laboring class, I always propose, as soon as I learn that the disease is not amenable to application of cold, rest, etc., exsection of the joint. I do not hesitate to propose such an operation, because I feel that it involves comparatively little danger, and it offers a good chance of eliminating the tubercular focus completely. The patient will afterward have a stiff knee, but the limb will be useful. It will not require constant repair, as a cork limb does. All that is required is a thick sole on the shoe. All of the patients on whom I have performed the operation have afterward been grateful that it was done. We should hesitate much longer before advising exsection in children, for in them the limb has not completed its growth. As you will remember, the growth of the lower extremity takes place from the epiphyses near the knee, and exsection of the epiphyses here finally results in considerable shortening. My first exsection of the knee was performed, about ten years ago, on a child three years of age. I saw that child lately, and found that the limb operated upon is about four inches shorter than its fellow. The case was treated by apparatus, by making incisions and counter-incisions, and such other means as would, if possible, save the joint. But this proved unavailing, and exsection or amputation had to be thought of.

You ask me whether I would exsect the joint if there is pulmonary tubercular infiltration? I have performed exsection of the knee-joint about sixteen times, and I do not think there were more than two cases of the sixteen in which there was no infiltration of the apices of the lungs. And in all of these cases there has been a marked improvement of the general condition, because of the elimination of one focus of disease at least. There are several reasons for the improvement which follows removal of the diseased bone. First, we take away a source of danger to life by stopping a constant drain to vital force. Secondly, as long as the local disease exists the man can take no exercise. By putting him in a condition to take exercise his appetite improves, he begins to sleep well, his muscles grow stronger, he becomes a new man; his lung trouble may not be entirely cured, but he ceases to cough, and the progress of the pulmonary tuberculosis is checked.

The method of operating will have to be considered at a future clinic.

ORIGINAL COMMUNICATIONS.

A GROUP OF CASES ILLUSTRATING SEVERE INFLAMMATORY AFFECTIONS OF THE CORNEA, IRIS AND CONJUNCTIVA, AND THEIR TREATMENT.

BY G. E. DE SCHWEINITZ, M.D.,

Ophthalmic Surgeon to the Philadelphia Hospital.

The group of cases recorded below present no new features; but they illustrate the value of certain lines of treatment, even when the outlook is most discouraging, and they warn against the dangers of inappropriate, though commonly employed methods of medication.

Granular Lids; Abscess of the Cornea.

Maggie C., aged 25, born in Italy, was admitted to the Eye-Wards of the Philadelphia Hospital on account of granular lids, most marked in the right eye, in which there was pannus, and just below the centre of the pupil a small, gray ulcer. Slight muco-purulent discharge and marked photophobia completed the symptoms. The topical remedies ordered were atropine drops and a solution of bichloride of mercury (1-8000), and internally, quinine and iron after the patient had been properly prepared by the administration of a mercurial purge and the daily use of

sulphate of magnesia. The left eye rapidly improved; the right did not, but the gray ulcer increased until the lower part of the cornea was occupied by a large abscess. The photophobia was most aggravated; the pain intense. A broad needle was passed through the abscess and into the anterior chamber, evacuating the contents of both. Hot water compresses, the water of a temperature of 120° F., and the applications made for ten minutes at a time every two hours, were ordered, and the internal treatment above described was continued. The results were most happy; the pain was instantly relieved, the photophobia diminished, and the slough in the cornea separated. A large ulcer, shallow except at one spot, where Descemet's membrane bulged forward, remained. The hot water was discontinued and a pressure bandage applied, under which the cure was completed, leaving an irregular scar which was fortunately below the pupil. The granular lids had improved also during this time, and, when the active and dangerous inflammation of the cornea had subsided, were treated with the usual remedies.

Ulcerative Keratitis; Hypopyon.

Jas. B., aged about 45, was admitted to the wards, with his eyes in the following condition: The right cornea was occupied by a dense, adherent leucoma, the result of former inflammation and ulceration, and was practically sightless. In the lower third of the left cornea there was a deep, irregular ulcer, and the bottom of the anterior chamber contained a good-sized collection of pus, whose upper level was a horizontal line. The patient was anæmic, and had upon his body the evidences of syphilitic infection—a specific leg-ulcer and numerous copper-colored cicatrices at the seat of former ulcerations. He gave a perfectly clear history of the initial infection, which had been followed by secondary lesions years before. This eye-lesion came on after exposure following a debauch. The bowels, which were constipated, were thoroughly moved with blue mass and sulphate of magnesia, and the man put upon twenty drops of the tincture of the chloride of iron and $\frac{1}{4}$ of a grain of bichloride of mercury, thrice daily. The hot water compresses, in the manner before described, were ordered; together with atropine drops and antiseptic washes. In twenty-four hours the hypopyon had so much cleared up, and the ulcer become so much less angry, that paracentesis of the anterior chamber was not deemed necessary. The recovery was uninterrupted, and the resulting scar was suf

ficiently below the pupillary space so as not to seriously interfere with useful vision.

Kerato-Iritis; Hypopyon. Two Cases.

Case I.—P. S., aged about 45, an Irish carter, came into the wards on account of kerato-iritis of the right eye. He had extensive ectropion of both lower lids and an adherent leucoma of the left cornea. The present attack began about ten days before he sought admission. The lower half of the anterior chamber was filled with pus, the entire cornea was hazy, and the iris discolored and attached to the capsule of the lens (posterior synechiæ). Severe brow and temple pain, and slight febrile reaction were present. The man denied syphilis and gave exposure as a cause of the inflammation. He was purged, put upon alterative tonics, and locally, atropine drops, bichloride of mercury collyrium, and hot-water compresses—the latter after the anterior chamber had been opened and the pus as far as possible removed. After a few days when, by the aid of the tonics and milk punch, the nutrition had improved, the former were stopped and iodide of potash in ascending doses ordered. The result was entirely satisfactory, and a useful cure resulted.

Case II.—John L., aged about 40, came to the wards suffering with a kerato-iritis of the right eye, complicated with hypopyon; in all particulars similar to the last case. The man was a hard drinker, had had syphilis and the inflammation had appeared during a prolonged debauch. The same treatment as in the last case was ordered, and, as there was marked insomnia, large doses of bromide of potash at night. Relief followed these measures, but the restlessness and brow and temple pains continued. Three ounces of blood were then drawn from the temple, and the pain diminished; but during the night the full symptoms of delirium tremens manifested themselves. Bromide of potash was then given freely during the day, and chloral and morphia at night. The attack subsided readily, and at no time during its continuance did the eye-symptoms grow more aggravated, the topical treatment having been industriously applied. The eye gradually cleared up, and the appearances returned to well-nigh normal, with the exception of several synechiæ, which did not tear loose under the atropine.

Serpiginous Ulcer of the Cornea Occurring in a Very Old Man.

A. J., aged 85, an inmate of the hospital on account of chronic nephritis, came to the

Eye-Ward for the following reasons: A few days previous to his admission, he was attacked with a slight conjunctivitis of the left eye, and this was treated with some simple astringents. During this time, it was thought, a foreign body entered the conjunctival cul-de-sac and abraded the cornea. Very quickly the eye took on an active and dangerous inflammation and, when he applied for treatment, presented this appearance: swollen and rigid lids, tarsal conjunctiva opaque, bulbar conjunctiva slightly thickened, and surrounding the cornea a dark red zone of congestion. The cornea was hazy throughout and lustreless like "that of a dead fish," while below there was an irregularly crescentic serpiginous ulcer, to the outer side of which there was a yellow line, indicating a collection of pus between the lamellæ of the cornea. Severe pain accompanied the local condition; the tongue was dry and furred; the bowels constipated. The treatment consisted in the administration of saline laxatives, Bashams' mixture, and milk punch occasionally. The eye was kept clean with a saturated solution of boracic acid, atropine drops were instilled, and hot water compresses applied. At first, the latter were used for ten minutes at a time four times daily, and later, for the same length of time, every two hours. This case, considering the circumstances and the age of the patient, has done well, and the dangerous local manifestations have in great part declined. The old man is still under treatment, but there is every reason to believe the result will be a useful eye.

Purulent Ophthalmia; Ulceration and Perforation of the Cornea. Two Cases.

Case I.—Margaret S., aged 30, the mother of five children, was admitted to the wards during the latter part of August. She had only tolerable health. There was no vaginal discharge and no history of infection from a specific source. About three weeks before admission, after a long night's sewing in an ill-favored and badly-lighted room, she was attacked with muco-purulent conjunctivitis of the left eye. Upon this, she tied the eye up with poultices of tea leaves, and, as it continually grew worse, she substituted for these one made of linseed meal. Under this treatment, the inflammation rapidly took on the purulent form, and one week after the left eye was affected, its fellow was similarly attacked, but, fortunately, less actively submitted to domestic medication. When examined at the hospital, there was great cedema of the lids, swollen and thickened conjunctiva, which freely secreted pus, and

on the left side a large perforation of the cornea into which the iris had prolapsed, and from the upper part of which a button of turbid vitreous was protruding. The eye-ball was soft, intensely tender, and partly collapsed. In the upper part of the right cornea there was a broad, semilunar ulcer of the serpiginous type, extending almost through the entire thickness of the cornea. The woman was suffering with intense pain in the eyes, especially the left, and violent throbbing pain in the left side of the head. The temperature was above normal. In spite of the existing panophthalmitis, the shrunken left ball was removed, the pain was directly relieved, and the temperature returned to normal. Frequent cleansings, with antiseptic solutions, atropine and hot fermentations, constituted the treatment of the right eye. This rapidly improved in its appearance, and all but the inner end of the semilunar ulcer healed up. At this point, however, during one night, perforation took place, with prolapse of the iris. A pressure bandage and eserine drops failed to decrease the size of the hernia. The sac was hence opened, the prolapsed iris seized, drawn slightly outward, and cut off. The bandage and eserine were continued. Thus far, the eye has done well, and through the resulting egg shaped pupil there is useful vision. That the eye was saved at all was a matter of congratulation. The internal treatment was quinine, iron and milk punch, with due attention to avoid constipation.

Case II.—Maggie B., aged 28, unmarried and a servant in a large sea-side hotel. Her work was washing and she was constantly exposed to wet and damp. She was a somewhat flabby, large-framed woman, of fairly good general health, and suffering from slight leucorrhœa. Seven weeks prior to her admission both eyes were attacked with ordinary conjunctivitis. She continued her work, and during the day bathed her eyes with iced tea, and at night tied them up with warm poultices of bread and milk. *Pari passu* with this treatment the eyes steadily grew worse, she soon was unable to attend to her duties, and when she came to the hospital she presented the following pitiable condition: The conjunctivas were fleshy, thick and covered with pus. The corneas were deeply ulcerated, perforated, and the apertures of the perforations occupied by prolapse of the irides and granulations. On the left side, the vitreous was freely escaping. The eyes, of course, were spoiled and sightless. Fortunately the woman suffered little or no pain. Antiseptic cleansings, atropine

and warm fomentations reduced the inflammation; but it was too late to save or restore sight to this unlucky woman.

REMARKS.—It is perfectly evident that the saving means of treatment in the cases of abscess of the cornea and hypopyon were the hot water compresses and incision of the cornea, with removal of the pus as far as that was practicable. Hot water as a method of combatting inflammatory diseases of the eye is by no means a new treatment, and only quite recently it has been deemed a worthy subject of papers presented to societies specially engaged in the consideration of eye surgery. The water should really be hot (120° F.) and the compress changed frequently enough to maintain this temperature. Otherwise applied the treatment may do harm. No matter how accurate the local treatment of an eye inflammation may be, the surgeon must not neglect the patient's general state. In syphilitic patients the temptation is at once to resort to the recognized anti-syphilitic remedies—mercury and iodide of potash. It should be remembered, however, that in those individuals who are the subjects of advanced syphilis, and in whom anæmia and cachexia are dominant symptoms, these remedial agents are sometimes productive of positive harm, always excepting the cases in which the lesion endangers life. In these cachectic patients the combination of tincture of the chloride of iron and bichloride of mercury is often a happy prescription. The case of keratoiritis with hypopyon, in which delirium tremens occurred as a complication, without interfering with the progress to recovery, is worthy of notice. It is interesting to observe that, while the prodromes of this attack of *mania-à-potu* were present at the time of the man's admission, the full development only appeared immediately after the cupping of the temple. The abstraction of blood acted as an exciting agent. The two instances of purulent ophthalmia are quoted because they are sad illustrations of the pernicious practice of tying up eyes, which are the seats of catarrhal inflammation, with warm poultices. Mr. Nettleship, in his admirable book on "Diseases of the Eye," has italicized this sentence: *The eyes should not be bandaged in any form of ophthalmia, and poultices are very seldom necessary.* It is a pity that this advice could not long ago have been italicized upon the minds of many people. Had it been possible fewer blind eyes would exist in the world to-day. The result in the case of the old man, the subject of serpiginous

ulceration of the cornea, was certainly gratifying, because of the dangerous character of the ulceration and the age of the patient. While atropine in this instance acted happily, it should be remembered that often in these cases, when the sclera is stiff or the tension above normal, sulphate of eserine is the more useful drug. It should be used in the strength of one grain to the ounce. It acts probably by decreasing the intraocular tension. The people in whom these eye lesions occurred were without exception the owners of depraved constitutions, an ownership that had either come by inheritance or else through a wilful or unavoidable disregard of the laws of health. They were all unfavorable subjects to work upon, and the fact that in most of the instances the result was fairly good, indicates the value of the methods employed. A distinguished medical teacher, when lecturing upon the management of opium poisoning, was accustomed to say: "Never stop treating your patient until he has been dead for some hours." Thus did he endeavor to impress upon his hearers that intelligent efforts often succeeded in resuscitating the poisoned individual even when all hope had departed. In like manner, it seems to me, thoughtful and careful treatment of an eye should not grow weary, even though that eye be upon the very threshold of blindness. The result will often be good when least expected.

1330 Spruce Street.

INFANTS' FEEDING BOTTLES.

BY W. M. POWELL, M.D.,

One of the Attending Physicians to the Children's Dispensary of the University Hospital, Philadelphia.

Prof. Louis Starr, in his lecture on Artificial Feeding, at the University Hospital, laid special stress on the proper kind of nursing-bottle to be employed. He exhibited three styles before the class, as follows:

First, the English nursing-bottle, which consists of a twelve ounce bottle with a perforated cap, which screws to the neck, through which passes a glass tube about six inches long; to this tube is attached a soft rubber tube about sixteen inches long, with a rubber tip at its extremity. The objections to this bottle are numerous. It is impossible to keep the glass as well as the rubber tube clean, the spiral turn around the neck of the bottle to which the cap is screwed is a resting place for dirt,

the bottle has too many angles and corners, which are difficult to keep clean. This bottle should never be used under any circumstances.

The second bottle shown was the ordinary eight ounce nursing-bottle without the rubber tubing, and simply supplied with a soft rubber tip. This bottle also has its objections, the sides and bottom meeting at an angle in which milk is apt to accumulate.

The third bottle shown (see cut) was made according to the suggestions of Prof. Starr. It is called the *Graduated Nursing Bottle*, and is made of transparent flint glass, thus showing plainly the slightest foulness at a glance. The interior surface is made entirely free from angles, and an accurately graduated scale of fluid ounces and half-ounces or tablespoonfuls is blown in the glass. This bottle will be found very convenient, accurate in measurement and easily cleaned, thus combining the conditions so essential to the successful hand-feeding of infants.

2205 Pine St., Phila., Nov. 18th, 1887.

—Scarlet fever has been remarkably prevalent in Boston during the last few weeks. There are probably about sixty cases at present in the city. Dr. Durgin, of the Board of Health, is reported as saying that he has no doubt but that the digging up of the streets had considerable to do with the increase in sickness.

CHLOROFORM IN SPASMODIC CROUP.

BY H. V. SWERINGEN, A.M., M.D.,

FORT WAYNE, IND.

On the night of Oct. 10, 1887, I was called in great haste to see a four year old boy, Klepper by name, whom I had upon several occasions treated successfully with emetics for spasmodic croup. The present attack, however, was more severe than any of his previous ones; and the usual dose of the solution of sulphate of copper, which had been already administered and followed by copious vomiting, proved of no benefit. Upon my arrival I found him apparently in a dying condition, completely cyanosed and almost comatose. The parents, although accustomed to seeing him and others of their children in similar attacks, were unusually alarmed at his frantic efforts to breathe, which were horrible to witness, and had called in the neighbors for what assistance they might render. A cloth wrung out of cold water had been wrapped around the child's neck, after vomiting, but without any benefit. I expressed the opinion that he would get better in a little while from the vomiting, which, in all prior attacks, had sufficed to relieve him, and generated fumes of tar and turpentine by placing some of these drugs upon the surface of water kept constantly boiling on a small coal-oil stove. But no relief came; on the contrary, he seemed to be growing worse, if that were possible.

I had a bottle of chloroform in my pocket, and, although it hardly seemed appropriate for a cyanosed condition, I concluded to see what it would accomplish. I always use chloroform for the relief of asthma, and why not use it for the relief of croup, which is similar in my opinion in its effects and calls for the same treatment? In the present instance the result was most gratifying, for the boy was speedily relieved, and has since made a good recovery.

SMALL DOSES.

BY JOHN AULDE, M.D.,

PHILADELPHIA.

That there is a tendency on the part of physicians to discontinue polypharmacy, and depend more and more on single remedies (specific medication), and prescribe smaller doses, no one will contradict. The innovation is commendable, and is one of the most promising features of the times. As a com-

plement, then, to the paper on "Large Doses," which appeared in the REPORTER, Nov. 5, 1887, I beg leave to submit the following remarks:

In certain heart affections, such as cardiac dilatation, one or two drops of the tincture of digitalis may be given three times daily with great benefit. Cardiac hypertrophy, on the other hand, may be materially overcome by the exhibition of one drop doses of aconite tincture three times daily. Acute inflammatory conditions, like tonsillitis, bronchial catarrh, and threatened pulmonary congestion, as well as headache due to arterial tension, are immediately and favorably affected by drop, or half-drop, doses of tincture of aconite every hour, or half-hour, for a few hours. Frequently, headache of the congestive variety, with a band-like feeling around the forehead, may be quickly relieved by drop doses of nitroglycerine, at intervals of five or ten minutes, until five or six drops are taken. The form known as "sick headache," dependent on a bad condition of the stomach, will often disappear in half an hour under the influence of two grains of potassium iodide dissolved in water, and taken in divided doses at intervals of from three to five minutes. Like aconite and nitroglycerine, gelsemium occupies an important position in cases of this class; but its uses are not so well recognized as that of the other drugs named.

Belladonna, or its active principle, atropine, in doses of one two-hundredth of a grain, is a valuable remedy in the incontinence of urine of children, a single tablet of that amount dissolved in water and taken at bedtime being often all that is required. Quinine, in doses of one-tenth of a grain, may be given to those who are unable, on account of idiosyncrasy, to take larger doses, and it will often be found that these small doses are sufficient. The tincture of hyoscyamus, in doses of from three to five drops, or one drop of the fluid extract, in combination with triticum repens, made up in the form of a hot tea, is an admirable remedy in cases of irritability of the bladder, with fugitive neuralgic pains about the abdomen and in the lumbar region.

In the treatment of certain classes of dysentery, a modification of Hope's camphor mixture will be found of signal service. The dose may be limited to two or three drops of the deodorized tincture of opium, with an equal amount of dilute nitric acid, or aromatic sulphuric acid, with sufficient camphor water to make a teaspoonful, and taken hourly or half-hourly, as the circumstances seem to

demand. In similar cases, where it is desired to produce an effect on the alimentary canal with a view to getting rid of objectionable matter, a single grain each of opium and ipecac may be combined with four grains of blue mass, and divided into eight parts, one part to be taken every hour, or half hour, with the happiest effect.

The malate of iron in minute doses is an excellent remedy as a tonic, and Blaud's pill, one three times daily, is often sufficient in cases of anemia, although it is usually stated that the dose should be from four to six pills. Small doses of nux vomica, one drop of the tincture, or one-twentieth grain of the extract, are frequently as serviceable as a tonic as the larger doses; while strychnine in doses of one-sixtieth to one one-hundredth of a grain, will accomplish all that is desired, when the stomach is in a suitable condition, and is much better, as it is much safer, than larger doses. In some cases of diarrhoea, five grains of bismuth, with an equal quantity of saccharated pepsin every two hours, acts like magic.

Dysmenorrhoea, the congestive kind, with belly-ache and excruciating headache and pain in the back, which is often seen in young girls, and women with displacements, can often be relieved by a single dose of ten drops of chloroform on a lump of sugar. Certain cases of this nature seem to do better with cannabis indica, and I have seen cases, which had resisted ordinary treatment for days, wholly relieved in an hour by the use of half-drop doses, at intervals of five minutes. Cannabis indica is a favorite remedy in trifacial neuralgia, and given in the manner indicated above, the pain will shortly disappear. Profuse diaphoresis may be produced by the frequent administration of half minim doses of extract of pilocarpus. Phosphorus, in doses of one one-hundred-and-fiftieth of a grain, given three times daily, will produce such an effect that it may be tasted by a susceptible patient for several days afterwards. Morphine in tablets containing one-fiftieth of a grain can be given in many instances with marked benefit. One drop of a one per cent. solution of the fluid extract of rhus toxicodendron is often an efficient remedy in stubborn attacks of sciatica and other affections of a like character. One-tenth of a grain of calomel, given every hour, it is well known, will produce an effect on the bowels equal to ten grains given at one time. Corrosive sublimate, one-fiftieth of a grain three times daily, is an excellent remedy in disease of the stomach with fermentation and eructations of gas. It is doubtful if we

have any better remedy for the treatment of boils and carbuncles than small doses of calcium sulphide, one-tenth of a grain every two hours. Last, but not least, is strophanthus, the heart tonic *par excellence*; two to five drops of the tincture should be given three times daily, in all cardiac affections where there is aortic or mitral insufficiency.

4719 Frankford Ave.

SOCIETY REPORTS.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN OPHTHALMOLOGY AND OTOTOLOGY.

Meeting of November 21, 1887.

Sarcoma of the Iris.

DR. HERMAN KNAPP presented the specimen and said: "Sarcoma of the iris is so rare a disease that the publication of even a single case need not be introduced with apology. The case was a well-marked, I may say a typical, example of this disease. It occurred in the left eye of a lady 53 years of age. Three and a half years ago she had a fibrous tumor removed from the lobule of the left ear. This tumor recurred, and was removed one year since. There has been no relapse noticeable so far. Four months ago she was first aware that the sight of her left eye began to be impaired; that a small colored tumor developed in the iris and encroached on the pupil. The growth had increased rather rapidly, and the eye was at times painful and congested. When she presented herself, September 8, 1887, the eye was free from irritation, of normal size and tension; but its vision was reduced to perception of light with perfect localization of the candle. At the outer, upper part, the iris was replaced by a reddish tumor, the size of a cherry-stone, extending over the adjacent third of the pupil. The iris was otherwise normal. There was adhesion of the pupil all around. The lens was cataractous. There was no increase of tension. There was at that time no other inflammatory disease perceptible. The eye moved freely, and was not painful. The other eye was healthy. The patient appeared to be free from any other complaint.

The diagnosis, sarcoma of the iris, being evident, the question arose, Can and shall we remove the growth and spare the eyeball, or shall we remove the whole eye? Having operated successfully in three cases and assisted Dr. Kipp in another, I thought of

saving the globe; but, on further reflection, I determined to remove the eyeball, chiefly for the reason that the pseudoplasm had damaged the adjacent structure so much as to make preservation of useful vision almost impossible.

The patient consented to enucleation, which was done without accident, and was recovered from in a few days. She has not had any discomfort since. The tumor proved somewhat larger than the displaced crystalline lens. It was elliptical: eight millimeters long, five millimeters broad. The tumor was completely circumscribed, and occupied the iris or the ciliary pupillary margin. Its front surface was covered by a thin layer of iris. Its starting point seemed to have been situated in the root of the iris, quite near the ciliary process. Its surface was smooth. It could be separated from its surroundings everywhere except at the attachment of the ciliary margin to the inner wall of Schlemm's canal. Its cut surface was white; it was coherent and moderately hard. Besides displacement of the lens obliquely into the vitreous, nothing remarkable was observed in the other part of the eye.

On microscopical examination, the growth proved to be a typical specimen of vascular round-celled sarcoma. A rich network of blood vessels with delicate walls pervaded the whole tumor. The diagnosis was primary, tubular, round-celled sarcoma of the iris.

Remarking further upon the case, Dr. Knapp said that these tumors are malignant. He had in three cases removed a sarcoma of the eye, only one of which had remained under observation. The tumor was removed in 1876. It had grown slowly, caused iritis several times before the operation; twice since; but since then the eye had remained free from irritation. Since an operation on the eye for cataract, the sight had remained good. The growth was a melanotic spindle-celled sarcoma; less suspicious than the round-celled, vascular growth in the case just related.

Dr. Knapp had been able to find but twenty one cases of sarcoma of the iris reported in medical literature, excluding the one just related. The diagnosis was principally based upon melanotic nævi. These latter might pass over into sarcoma. Speaking of the operation for removal of the growth, sparing the eyeball, Dr. Knapp said he would not hesitate, after its removal, to go in and cauterize the ciliary body; the action of the galvano-cautery would be entirely local.

DR. WEBSTER and DR. ANDREWS recalled a case of sarcoma of the iris operated upon by Dr. Agnew about six years ago. The pain following removal of the growth necessitated enucleation a few days later.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, November 9, 1887.

The President, J. SOLIS COHEN, M.D., in the chair.

DR. DEFOREST WILLARD read a paper on
**Foreign Bodies in the Urethra and Bladder.
 Removal by Litholapaxy Evacuator
 with Large, Straight, Open-
 ended Canula.**

My object in bringing before you the subject of urethral and vesical foreign bodies is simply to emphasize the value of the evacuator (ordinarily used in rapid lithotripsy to extract the calculous fragments) for removing other more or less solid substances that have found their way into the urinary tract, either by accident or design.

Foreign bodies enter by various routes. Projectiles may reach the viscus and remain in its cavity; bones may be driven in by crushing forces; foetal remains may ulcerate through from extrauterine cavities; intestinal contents may occasionally make their way into the bladder, but all these are either rare, or are accompanied by such traumatism that death frequently ensues.

The bodies that we will especially consider are those introduced through the meatus urinarius, urinary calculi being only incidentally considered.

The strong tendency for manipulation of this part of the body that exists from early childhood to decrepit old age, leads to many instances of misadventure. Think of a lad actually sliding a watch-chain down his urethra. Examples of inserted beads, pebbles, sticks, etc., are numerous in childhood. After puberty the tendency becomes more marked as the sexual desire increases. A few years later we find the morbid recluse, especially among the shepherds and monks of former centuries, resorting to intra-urethral stimulation with sticks or other hard substances to arouse the over-exhausted functions, waning from excessive masturbation or venery. Yielding himself to his vile erotic feelings, the instrument often slipped from his fingers and was lost in the canal. Sexually insane must have been the shepherd who

had used for this purpose his pocket knife, after manual friction and urethral stimulation had proved unsatisfactory, until little by little, through hundreds of these indecent acts he had laid open the entire penis along its dorsal aspect until the pubes were reached, and the penis hung in two halves, united only by the lower wall of the urethra. Then with a short stick he was able to tickle the very orifices of the ejaculatory ducts. This stick, slipping into his bladder, became encrusted, and it was not until the pain became torturing, that he confessed the cause. Pipe-stems, pencils, thermometer tubes, glass rods, straws, needles, wires, twigs, hairpins, fruit stones, and even forks and lockets, have all been found in the urethra, after introduction for stimulative purposes, or to relieve dysuria from stricture or other causes. In one instance¹ a man introduced a sewing needle of the girl whom "he desired to fall in love with him."

At the present time we have fewer of these lecherous accidents, save from drunken debauchees, but the majority of instances occur from the use of old or improper catheters or bougies. Of course, these accidents are more frequently found in men than women, as the former are more subject to urethral disease, and are also more erotic, but there are instances in both sexes.

In children, small round bodies, as beads, etc., are found in the anterior part of the canal, while the longer instruments at all ages slip back to the membranous portion of the tube, or into the bladder.

Usually a long foreign body will find its way into the bladder in a few hours; rarely, two or more days may be required. In exceptionally rare cases, rounded bodies remain a long time in the urethra, the urine following a tortuous course around them, and, becoming encrusted, a pocket ultimately forms, or suppuration ensues.

It is not strange that catheters and similar instruments are broken off in the canal when we learn of the recklessness of a man who used one gum catheter for twenty years, or of another who attached two portions of a silver tube simply with sealing wax.

A too short instrument has often eluded the grasp of the surgeon and slipped bladderward.

As to this recedence of instruments, which is strong and actual, there have been many theories. It does not seem strange to me that the compressor muscular fibres of the urethra, when stimulated to action by a

body applied in front, should reverse their usual action as easily as do the muscles of the pharynx, cesophagus, intestines, etc. This act of swallowing a hard substance is aided by the erection of the penis, which in its subsidence (should the anterior end of the object become engaged), drives it further and further back with each successive engorgement. Tending to the same unfortunate end are all the manipulations of the part, in the patient's endeavor to extract the offending body.

Unfortunately for the safe extraction of these bodies, the surgeon has to meet with a large amount of deception upon the part of the patient, when the object has been self-introduced, and it is often impossible to obtain any reliable information either as to the presence of the foreign mass or as to its conformation. In broken bougies the surgeon should, if possible, have the other remaining fragment in his hand for measurement, or else secure one of similar size. Any object of peculiar shape should be accurately described, or duplicated. It must be remembered, that while a patient may confess to the introduction of but one body, there may be several. The position in the canal must be thoroughly fixed. In the ante-scrotal region this is easily accomplished, and with the aid of a sound and a finger introduced into the rectum even the posterior urethra can be well examined, provided inflammation be not too severe. When possible, no manipulations should be attempted for extraction without the body being firmly secured from further recedence.

Ether is of the greatest value, but cocaine injections may answer for urethral work.

Treatment.—About one-tenth of inserted foreign bodies will be spontaneously expelled, but when the *vis à tergo* of the urine fails to wash out either a calculus or an object inserted through the meatus, the safest and surest plan is to attach to an ordinary litholapaxy evacuator (Bigelow's or other improved pattern) a large, straight tube, which is open at both ends. It contains a movable stylet for ease of introduction. The size should be the largest that the urethra will possibly admit (after nicking the meatus, if necessary), say French No. 29 or 30; American, No. 19; English, No. 16, for adults; children in proportion. The possibility of the passage of the body through the tube should be determined, if possible, by actual trial, provided a similar piece can be obtained. Rarely will any bougie larger than the above-named sizes be found in the bladder or urethra.

¹ Poulet: Foreign Bodies in Surgery.

The method has been so satisfactory in my hands, as is proven by the collection of objects before you, that I always resort to it with confidence, to the exclusion of all other primary devices.

If the lodgement has occurred in the urethra, the canal must be firmly closed by finger pressure behind the object, while the metallic tube is slid down and carefully caused to engage the catheter or other mass within its calibre, when the bulb of the instrument is slowly compressed until the water has distended the urethra to its fullest limit, thus liberating the body, when suction is suddenly applied while the penis is stretched forward. Unless the mass be firmly caught and embedded in a pocket, this manœuvre rarely fails after a few trials. The quantity of water that can be contained in the urethra is so small that the body may require two or three efforts to withdraw it the whole length of the instrument. The water should be ejected very slowly, but the suction current must be made forcibly. Inspection of the rubber tube can be made through the upper opening without detachment of the catheter.

Avoid employing forceps until unsuccessful with the above method, but when necessary to be used, the superiority of the canula again asserts itself. The forceps can be manipulated through its calibre, and if the object be compressible enough to pass the bore, withdrawal can be accomplished without the slightest injury to the mucous membrane. Objects of larger size than this tube can seldom be withdrawn with safety by any method save cutting. Hairpins can be compressed through the walls of the urethra, and their points passed into the calibre, when they can be completely pushed within the bore and easily withdrawn.

Beads, peas, pebbles, etc., will easily enter the canula by suction. Catheters, wires, etc., will usually require the assistance of forceps. Barbed heads of grain can also be sheathed and withdrawn by this device.

If the object has passed into the bladder, the evacuator becomes an even more essential aid. A straight instrument is not always easy of introduction, but the security gained against subsequent urethral injury abundantly repays for the trouble. If a flexible or spirally cut obturator is used, the introduction is rendered much easier. The tube is used first as a sound to discover the offending body, when the bulb of the evacuator is first slowly compressed, so as not to disturb the fragment. Suction should always be made quickly, so as to draw the body with force. Failing, the water is next ejected with more energy, so

as to move the fragment into better line with the calibre, suction being again rapidly applied. The hard substances will not be driven against the sides of the bladder with any more power than are calculus fragments, and unless consisting of broken glass will not be as angular. If the body is rounded, and of a size that can pass the bore, it will in a few moments be found in the bulb. If very long, like a catheter, or pencil, or wire, the chances are not so good that it can be brought into line with the calibre of the tube. As a bougie ordinarily breaks at or near the eye, however, its passage is more than probable. Failing, after ten minutes of gentle trial, a lithotrite should be introduced if the body is a bougie or pencil, and is capable of being cut or pinched in two, and the division made. A cutting lithotrite, like Caudemont's, is manufactured, but I presume is seldom found among the paraphernalia of surgeons, and the fenestrated instrument of Thompson is far safer. If the bougie is old and brittle, as is presumptively the case, such division with a lithotrite is easily accomplished. The segments can then be sucked out, and their total length carefully compared with the remaining portion or lost body. Every particle must be secured, lest it form the nucleus of a future calculus. Even the broken jaw of a lithotrite might be drawn into the bore.

If the surgeon has not the straight tube with open end, which I advise, he may use the ordinary straight evacuating tube. Rounded bodies, and pieces of bougie small enough and flexible enough to enter the side opening can often be secured with ease, but long or rigid pieces can only be drawn through the open-ended tube. This tube has the disadvantage that the point must be kept just inside the neck of the bladder. If pushed too far, the posterior bladder wall flaps against it; if withdrawn too much, it is concealed in the prostatic portion, and makes no suction upon the vesical contents. Its safety from impaction of fragments in the eye, however, more than counterbalances this slight trouble; since, in the ordinary evacuating tube, a large fragment often cannot be dislodged from the eye, and lacerates the urethra during withdrawal.

Should these manipulations fail (and, if they have been carefully conducted, no injury need have been done to the bladder), I show you how two forms of forceps which I have had made of just sufficient length to be slightly protruded from the end of the tube. In the one the jaws open by a spring, as in the old Halles forceps; and in the

other the jaws are worked by handles, as in the Mathieu and Gross and "alligator" patterns.

Careful attempts can now be made to seize the body and extract it through the catheter. If small enough to be brought through, it is a great satisfaction to know that no possible injury can be done to either the neck of the bladder or the urethra, as is so likely to occur when a body is extracted in the jaws of a lithotrite. Necessarily, only a small proportion of introduced objects can be removed per urethram; and I should lay it down as a rule that any foreign body too large to pass the calibre of this No. 29 tube, unless it be very soft and pliable, should be removed by lithotomy, either perineal or suprapubic. Lithotomy has its dangers, but laceration is worse.

The suprapubic is at present the fashionable operation, and it certainly presents many inducements in its favor. The median perineal operation, however, is a safe one, and gives excellent results. No important structures are severed, and there is seldom troublesome hemorrhage if the raphe is closely followed. By either of the routes, great care must be exercised in the search if the object be sharp-pointed, lest a perforation be made. The inflation of the rectum in order to lift the bladder must be dispensed with if the object is sharp-pointed. The upper route gives more room, and, while there is a slight risk of wounding the peritoneum, yet we must remember also, in the extraction of large objects as well as calculi by the perineal route, that the rectovesical fold of the peritoneum is in close proximity to the neck of the bladder, and may not escape involvement in the subsequent inflammatory action.

If the walls of the bladder were only of sufficient strength to warrant their immediate sewing with catgut or silk, and permit primary union under strictly antiseptic dressings while the urine were drained off below, the suprapubic route would certainly be decidedly the better one; but, as this is not the case, there is still room for honest differences of opinion in the selection of an operation. For the present, we must be content to drain the suprapubic wound.

In the absence of an evacuator, the expulsive force of the urine is often sufficient to dislodge a urethral impaction, especially if the meatus is closed for a moment so as to obtain the full dilating power of the water. Failing in this effort, if the foreign body can be located and the urethra closed, a argé injection of sweet oil may be thrown

in, after a hot bath, and the largest possible bougie carried down to the body to stretch the membrane, while pressure from behind is made, either by the surgeon's finger or by the expulsive efforts of the patient's bladder.

Should lodgement be made in the fossa navicularis, the spoon of the ordinary pocket-case can often be hooked behind the object and assist in coaxing it forward. A hairpin, or wire doubled upon itself and slightly bent, or a blunt curette, makes also a valuable extractor. An excellent instrument also is the articulated scoop of Leroy d'Etiolles, which, being introduced past the foreign body, has a mechanism by which its tip is then bent at right angles to the shaft, and is capable of making strong but dangerous traction. The abruptly short-beaked sound which I always use for sounding the bas fond of the bladder can sometimes also be "wormed" past the obstruction and effect its dislodgement. I show you here seven prostatic stones that I have thus extracted, aided by the force of the urine. Long urethral forceps are of great service, as they serve partially to protect the canal during extraction; but they do so far less effectually than does the straight tube before described, which should be placed in every evacuating set. Hunter's or Civiale's three-bladed forceps are occasionally used; but I always look with abhorrence upon dragging any object forcibly through the canal. A dangerous instrument is the urethral lithotrite of Reliquet, as *incision* is infinitely safer for all rough and large bodies.

When the substance lies posterior to the triangular ligament, gentle attempts should be made to push it into the bladder, only after the evacuator has failed to dislodge it. If necessary to operate, the raphe should be closely followed, while a large staff is held in position to indicate the location of the obstruction and of the tube.

An incision in front of the scrotum is easily made, and should be closed after the removal of the body by catgut or quilled sutures. Treated antiseptically, and with either a retained catheter, or with frequent catheterizations, immediate union may be confidently expected. The quilled suture gives more perfect rest by its splint action.

If a stricture exists, and the foreign body is lodged behind it, dilatation or free external incision of the stricture should be practiced.

In former days, the instruments for search and removal of these objects, greatly exceeded those of the present day, when operative procedures are more common. The

"duplicators" of Mercier, and of Charrière, were intended to fold up any soft substance, as a very flexible bougie. Long stiff bodies were seized by "redressors" or "basculeurs," forceps with bevelled blades, constructed so as to rotate the body so that its long axis would correspond with that of the instrument. Occasionally a small lithotrite will answer for either of these purposes, but the great danger of laceration, during withdrawal through an unprotected canal, must never be lost sight of.

The curved forceps of Cusco or Voillemier are, perhaps, as useful in the bladder as in the membranous urethra; but I am afraid to use them for the reasons already named, especially since I have found suction so much safer and also more effectual.

For the removal of pins, bonnet pins, or needles, from the urethra, the point can sometimes be imbedded in a wax or gum bougie, but it is easier washed out with the evacuator. If immovable, the point can be pushed through the walls of the urethra, and by sharply bending the penis, the head after reversal drawn through the tube by suction or by forceps. It is seldom necessary to cut the pin when this method is used.

If a piece of nitrate of silver is lost from a porte-caustique, the evacuator, charged with salt water, should be at once used if the force of urination does not expel the mass.

Many ingenious devices have been practiced in the absence of instruments, to rid the urethra of impacted bodies, but the knife is far safer than rough instrumentation. In the absence of the straight evacuating tube,

an extra sized catheter, with open end, and a large syringe, might prove useful.

Blood-clots in the bladder are practically foreign bodies, and are best removed by gentle suction through the curved evacuator, or through the blood catheter, which I here show, the large eye of which is closed down during introduction by a spirally cut obturator.

Catheter accidents are so frequent that instruments should be often examined. Only recently I found that the distal extremity of my much-used pocket case instrument could be slipped from its screw-thread by a very small amount of traction. Old gum bougies should be thrown away as soon as they begin to lose their elasticity.

To summarize:

1. The litholapaxy evacuating tube, large, straight, and with open end, is the surest and safest instrument for the removal of foreign bodies from either urethra or bladder.

2. The fenestrated lithotrite should be employed to break up all bodies capable of division.

3. Incision of urethra or bladder is safer than a tear of the neck of the viscus or of the canal.

4. The suprapubic and median perineal are the safest routes of entrance to the bladder when suction fails.

5. Forceps should be used with the greatest care, and always through a straight tube, which insures protection both to the urethra and neck of the bladder during both exploration and extraction.

EDITORIAL DEPARTMENT.

PERISCOPE.

Therapeutics of Chronic Articular Rheumatism.

At the Sixtieth Congress of German Naturalists and Physicians at Wiesbaden, in September, 1887, Ziemssen read a paper on this subject, in which he made the following points: 1. Chronic articular rheumatism is a general disease: though at times it may be quite localized, yet there exists no surety that the disease may not again become general. 2. Therefore treatment must at the outset be general. 3. The disease is often so inveterate at special points that a combined local and general treatment is necessary. 4. In the affected joints are almost always found

separate spots with a distinct border, which can be accurately marked out by touch and by the sensation of pain on the part of the patient. 5. The pain is often complicated in such a way that either the diagnosis is doubtful, as in arthritidis, syphilis, gonorrhœa and after injury; or that the pains belong to another kind of rheumatism, for example, muscular rheumatism, rheumatic neuralgia, sciatica and heart-disease. 6. Such complications are to be dealt with at the same time with the general disease. 7. Treatment is not to cease before complete cure is obtained, otherwise a relapse would not be surprising. The rheumatic diathesis itself is the uncured disease.

Treatment is general and local. General treatment consists in the regulation of nutri-

tion, in an out-door life, in promoting increased activity of the skin, in the use of warm and hot baths, in wearing woolen clothing, and a regulation of the whole style of living; and finally in large doses of salicylate of soda. This remedy is, when rightly used, very well borne, has no contra-indications, and acts so specifically that when failure results from its use an error in diagnosis is to be inferred. The local treatment, which is to be employed simultaneously with the general treatment, consists in the use of massage, combined with warm douches while the patient is in a warm bath. By means of tubing and a bellows, a stream of water, under a pressure of three to seven atmospheres, is projected against the affected part, which at the same time is manipulated by a skilled attendant. This treatment excels all other local measures. In other rheumatic affections, such as muscular rheumatism and sciatica, this method of treatment by douche is very efficient.—*Deutsche Medizinal-Zeitung*, November 3, 1887.

A Case of Suppurative Peritonitis.

George J. Robertson, surgeon to the Oldham Infirmary, reports a case of suppurative peritonitis to the *Medical Chronicle*, November, 1887, the history of which is briefly as follows: Fred. O., three years of age, on December 31, 1885, fell, striking his belly against a small boulder, which was fixed in the corner of a street. He returned home evidently in great pain. Following the injury he became dull and languid, gradually failed in health, and became fretful and disinclined to play. He complained of pain in the belly, the right side of which was tender on pressure. He also for some time walked as if slightly lame, and with the body inclined to the right. Nevertheless he was able to walk a mile to the doctor's house on April 29. An examination made at this visit developed pain in the cæcal region, with a feeling of ill defined resistance, but no dullness on percussion. Symptoms of suppurative peritonitis—abdominal pain and distension, nausea, fever and rapid wasting, semi-recumbent posture, with legs drawn up—became so pronounced that an abdominal section was deemed justifiable, and was performed on May 14. The abdominal cavity below the umbilicus was found to be converted into an abscess sac, the upper limit of which was formed by coils of intestine glued together by recently effused lymph. No perforation seems to have been discovered in the region of the cæcum.

The cavity of the abdomen was thoroughly washed out with several quarts of warm water, every care being taken not to disturb the cohesion between the coils of the bowel. Drainage was provided for by rubber tubes.

Within a few hours after the operation, the general condition of the patient had improved, and convalescence continued so satisfactorily that, by June 3, the last piece of drainage tube was removed, and, by July 17, the abdominal wound had entirely healed.

The Connection between Syphilis and Tabes Dorsalis.

H. Nägeli, in a dissertation published at Zürich, in 1887, discusses forty-six cases of tabes dorsalis lately observed in the polyclinic and in the private practice of Professor Bernhardt, at Berlin, and expresses the opinion that of the forty-six cases twenty-eight, that is to say sixty per cent., had syphilis. He then gives a summary of all the existing literature bearing upon the relation between tabes and syphilis. Of the 1403 cases collected, syphilis had certainly preceded in 46 per cent., while 14.5 per cent. were suspected of syphilis. On the whole, therefore, the number who certainly had syphilis, plus the number suspected, comprised 60 per cent. of all the cases. On the other hand, an examination of 1450 persons who were non-tabetic showed the presence of syphilis in only 22 per cent. of the patients.—*Centralblatt f. d. med. Wissensch.*, Sept. 10, 1887.

Cocaine in Diseases of the Stomach.

At the meeting of the French Society for the Advancement of Science, at Toulouse, in September, 1887, M. Salet stated that he had arrived at the following conclusions:

1. Cocainé acts upon the mucous membrane of the stomach and intestine just as strongly as it does upon external mucous membranes.

2. In order that the action may be complete, remove the gastric and intestinal secretions, and combine cocaine with alkalis.

3. To this mixture may be added some morphia, in order to make the duration of the action as long as possible.—*Deutsche Medizinal-Zeitung*.

—The news from Europe indicates that there can be no doubt that the Crown Prince of Germany has an epithelioma of the larynx, and that it is progressing rapidly.

A Case of Profuse Galactorrhœa.

Dr. S. Gottschalk, of Berlin, reports the following case in the *Deutsche Medizinische Zeitung*, October 10, 1887:

Marie Mitschriek, a girl twenty-two years old, who never had been seriously sick, began menstruating at the age of sixteen. Menstruation was regular, but scanty. On January 23, 1887, she was delivered of a child at seven months, which died eight days after birth. Following confinement, menstruation was not resumed; but a galactorrhœa set in, which was so profuse as to make it impossible for her to keep the neighborhood of the mammæ dry, although she changed the linen three or four times a day. If the breasts were not compressed by bandages, the milk escaped in jets. As a result of the constant wetting of the skin, a severe eczema developed over the whole anterior surface of the thorax. As the health of the patient steadily declined, while the eczema rapidly increased, treatment was sought for the skin affection; but the cause of the trouble being recognized, she was referred to Dr. Gottschalk. The latter found, on July 22, that the woman was very cachectic, and that both mammæ and the surrounding surfaces, as far down as the liver and stomach, were covered with a very pronounced eczema. The mammary glands themselves were flabby, and from the nipples there was constantly discharged a fluid resembling milk and water. On the whole, the patient presented a phthisical aspect (her father was phthisical), but no objective signs of lung disease were demonstrable.

An examination of the uterus disclosed atrophy of the organ with a mucous discharge from the external os. The vagina at its entrance was eroded, while both vagina and uterus were very flabby. Thinking that this condition of affairs explained both the amenorrhœa and galactorrhœa, the author simply anointed the breasts with vaseline, and applied cotton over it to keep the tissues dry; and then directed treatment to the uterus. The latter was repeatedly scarified, superficially, twice a week. For the erosion, the patient used at home vaginal irrigations of lukewarm water, with the addition of pyroligneous acid. Internally, the patient was given the solution of the albuminate of iron.

The secretion from the mammary gland steadily diminished from the beginning of the scarifications, and ceased after the treatment had been continued three and a half weeks. The eczema vanished with the galactorrhœa, simply under the use of vaseline;

the cavity of the uterus showed the normal dimensions on being tested with the sound; the tissues around the uterus have a much firmer consistency; and, though menstruation has not yet been freely established, the general condition of the patient is quite favorable, and her weight has increased.

Avulsion of Ingrowing Nail Under Hypnotism.

Dr. S. L. Trivus, of St. Petersburg, relates (*Vratch*, No. 31, 1887, p. 607) a case in which he removed an ingrowing nail from the great toe of a cook after a hypnotic state had been induced in the patient. The operation lasted about twenty minutes. At first the woman occasionally moved her foot about, but when the author had suggested to her that no more pain was to be inflicted, and that the foot must be kept at rest, she sat quiet till the matrix of the toe was incised. At that point of the operation she shrieked out, and, when questioned about the cause, stated that "a dog had just bitten her." After applying the dressing, Dr. Trivus woke her up, and asked whether she would consent to the operation. She hesitated a little, and then said, "Yes, go on." On his pointing to her bandaged foot, however, she at once guessed that all was over already, and burst into laughter followed by hysterical sobs. No pain was felt till the next day, when she became somewhat lame. Dr. Trivus also relates an instructive case in which a young man of 25, after having been hypnotized for the sake of experiment, and subsequently awakened, could not return to his normal state for several hours; when left alone, he was seized with a kind of hypnosis, and on his way home fell into a deep swoon in the street.—*Brit. Med. Journ.*, Oct. 15, 1887.

Treatment of Erysipelas.

In a recent work on the antiseptic treatment of wounds, von Nussbaum strongly recommends the treatment of erysipelas by smearing the inflamed area with the following ointment:

B. Ammonii sulphoichthiolici.....1 part.
Lanolin.....2 parts.
M.

—*Centralblatt für Chirurgie*, Oct. 22, 1887.

—There have been eight cases of yellow fever and four deaths in Tampa, Florida, for the week ending November 23; making altogether 380 cases and 71 deaths.

O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6500 copies.

THE PHYSICAL DEVELOPMENT OF AMERICANS.

For a long time it was generally believed that the physical development of Americans was inferior to that of Europeans, and certain prophets of evil maintained that the average standard was becoming lower. The first of these beliefs may have been correct some decades since; but we think it is not correct now. A comparison of people in similar circumstances of life shows, we think, that the inhabitants of the United States are physically the equals of those of any country in Europe. One who has studied crowds, or bodies of soldiers, on both sides of the Atlantic, must feel that America produces men and women who are in no sense inferior to men and women anywhere. As to the idea that the physical development of our countrymen is deteriorating, it is interesting to note the result of personal observation and systematic study of this matter. We think that any one, who has had the question of the physical development of Americans in mind

for some time, will testify that personal observation leads to the conviction that the average duration of life, degree of health, and size of the bodily frame is increasing in America. The children are better developed, healthier and handsomer than they were twenty or thirty years ago; men are young men in spirit and in capability at forty and even fifty years of age now-a-days; old men and women retain their faculties longer than they used to do. In Philadelphia, the statistics of the *Public Ledger* leave no room for doubt on this subject.

As to the matter of bodily size, an interesting article from *Science*, Nov. , 1887, which we publish elsewhere, indicates that Americans are advancing, not deteriorating, in physical development. The investigations referred to show that in height and in girth the inhabitants of the United States are outstripping their predecessors, while in both they reach a standard which is very reassuring to those who may have been alarmed by the laments and solicitude of the ill-informed or timorous.

THE TREATMENT OF TYPHOID FEVER.

One of our subscribers has written to ask for an editorial upon the treatment of typhoid fever. This is a subject which might occupy much more space than falls within the limits of our editorial columns; but it may be possible within this space to offer a few suggestions which may be useful.

In the first place, we feel that most cases of typhoid fever require at the outset free cleansing out of the bowels. For this purpose a full dose of calomel or of blue mass, followed by some simple saline aperient, may be used. Afterwards, rest to the intestines may be secured by the use of a diet of milk, or broths, or of cocoa prepared with milk, in moderate quantities. The kidneys and skin may be kept active by the frequent administration of small quantities of sweet spirits of nitre in water. High temperature may be reduced very satisfactorily by the application of cold to the abdomen. A good plan is to lay a folded towel, which has been wrung

out of cool water, upon the abdomen, and to "iron" it with a piece of ice, when it gets warm. This method is often not only very efficient in reducing hyperpyrexia, but very agreeable to the patient, and we have some reason to believe that it acts beneficially upon the local inflammation of the intestines. If any drug be chosen for reduction of temperature, we think it should be antifebrine, giving fifteen grains at the start, and five grains every hour afterwards, until thirty grains in all have been taken, or the temperature has fallen two or three degrees Fahrenheit.

The systematic medication of typhoid fever patients should be confined within the narrowest limits possible. Often a dilute acid, like hydrochloric acid, will be all that is called for, and may be given in five or ten minim doses every four hours, in a dessert-spoonful of elixir of calisaya, or a teaspoonful of tincture of lavender or cardamon.

For hemorrhage from the bowels, we know of no better remedy than gallic acid, in ten grain doses, given every hour until about a drachm has been taken. For syncope from hemorrhage, teaspoonful doses of whiskey in hot water are useful. For delirium, we know no good medicament, believing that it can only be benefitted by relieving the general condition which gives rise to it.

Our own experience has included a case in which there was hemorrhage from the bowels, from the kidneys, and from the lungs in the same patient. Although this patient, as might be supposed, came very near to death, and seemed for a few anxious hours to be beyond recovery, she ultimately got well. This case is mentioned to show that even a desperate case may recover with comparatively simple medication. It is true that cases treated simply may die; but experience and observation have led us to the conviction that in no disease is "incendiary medication" more dangerous than in typhoid fever; and, at the risk of unfavorable comment, we will add that we regard quinine, administered in large doses, as the most dangerous kind of medication in typhoid fever. Turpentine, which was so long considered almost specific

in typhoid fever, has lost its prestige; and cold baths we have never needed since adopting the plan of applying cold mentioned above.

In conclusion, we would commend to our readers the idea of simple medication, careful feeding, attention to the emunctories, and patience and courage. The latter qualities are often called for in the treatment of typhoid fever, and especially when grave conditions tempt one to institute methods of procedure or to administer drugs which, we fear, are sometimes the cause of the very issue they are intended to avert.

THE INFLUENCE OF TYPHOID FEVER UPON INSANITY.

"It is an ill wind that blows no one good." The appearance of typhoid fever among the patients at the State Hospital for the Insane, at Norristown, Pa., has given rise to a great deal of anxiety; but it has had a most fortunate and curious result in curing some of the patients, who contracted the fever, of their insanity. One woman, about fifty years old, who had suffered with chronic melancholia for several years, has been discharged perfectly well. Another patient, about twenty years of age, who had been in the hospital eight months with a second attack of acute mania, though subsiding somewhat at the time of the invasion, has gone home perfectly well. Another patient, a girl about eighteen years old, was beginning to recover from acute mania, when she sickened with typhoid fever. After the fever left her she seemed quite bright, although she is now inclined to be very dull and stupid. At any rate, a decided change has been produced in the mental condition of this patient.

It is well known that the bodily conditions are frequently altered after typhoid fever; the lean may grow corpulent, and those who were previously fat may grow lean. But it is not so generally known that disturbances of the cerebral functions are favorably affected, or that even the moral principles of an individual may undergo a

CORRESPONDENCE.

The Conjugal Question.

EDS. MED. AND SURG. REPORTER :

decided change. After this fever some persons have been known to develop a propensity for stealing. Dr. Crothers reports the case of a student of theology who, on recovering from typhoid, "betook himself to such a life as compelled him to pass most of his time in jail."

Dr. W. F. Waugh reported similar cases to the Pennsylvania State Medical Society in 1886. One young man, after being ill with typhoid fever for thirteen weeks, exhibited the delusion of grandeur and developed most unnatural tastes, acting consistently the part of the wealthy youth who is sowing his wild oats. A more gratifying phase of this mental revolution was the development of a talent for the work of a solicitor, which he never exhibited before his illness.

These curious results indicate the profound influence which such a disease as typhoid fever may exert upon the human economy, and discover it in an unexpected rôle of beneficence. In such cases as we have referred to it has proved a blessing, although a blessing very well disguised.

A HOSPITAL QUARREL.

Recent numbers of the *British Medical Journal* report a very unfortunate state of affairs in the Mercer's Hospital, Dublin. It appears that grave charges have been brought against Mr. O'Grady, senior surgeon to the hospital, by Dr. Knight, one of the physicians, including neglect of duty, abusive language to the governor, and uncivil treatment of the matron and of a fellow-surgeon. These charges were met by a general denial from Mr. O'Grady, and by counter-charges of animosity on the part of his accusers, and of offences which justified such proper reproofs as he had made in certain cases.

It is hard to judge of the merits of a controversy at a distance, and the evidence published in the *British Medical Journal* does not suffice to decide the merits of this one. But it clearly appears that the Mercer's Hospital is in a very unfortunate predicament, and that either the dissensions of its officers, or its bad management, or both, have dimin-

Sirs :—Having noticed some little discussion upon "The Conjugal Question" in the columns of the REPORTER of late, I venture to make a few comments upon the subject in its relation to health and disease. In several instances I have clearly traced the cause of a broken constitution and poor health to excessive sexual indulgence. Such a cause is generally denied by both parties when questioned directly upon the matter; and when cornered they will reply that they did not know that such indulgence was excessive. I have known of parties who indulged in the sexual act every night, excepting when menstruation was in progress, and to keep it up for long periods of time. The wife was not the only one to suffer, but in many instances the husband also, while in some cases the wife apparently was undisturbed, while the husband would be the one to complain. These are not fancies, but facts. Only a year or two ago, in a town not far distant from here, there were several reported cures among women who had been afflicted with poor health, the party treating them being a traveling quack, who in each instance said that the husband must sleep in a separate bed during treatment. I do not pretend to say that either party was brutal or more to blame than the other, but that such a state of affairs is more prevalent and responsible for more injury than the profession generally apprehends, calling for a consideration of it as a factor in the treatment of certain classes of disease. I have also seen weakly persons of both sexes benefitted by marriage, and it is only when certain physiological laws are perverted that it ceases to be a virtue.

Wiota, Iowa, Nov. 18, 1887.

Painful Tumor Near the Cæcum.

EDS. MED. AND SURG. REPORTER :

Sirs :—There is a disease near the cæcum which I have never seen mentioned in any of our books, and the only account of it, of which I have any knowledge, is by Dr. James Jackson, of Boston, some forty years ago. During the last thirty years, I have met with this condition thirteen times.

It may be known by a sense of uneasiness in the iliac region, which gradually increases to pain; and if neglected, it will resemble the symptoms of partial enteritis. The bowels

are always constipated. The part is tender and upon pressure, a tumor, somewhat larger but flatter, than an almond, may be detected and it is somewhat moveable. It can be found on a line drawn from the ant. sup spinous process of one ilium to that of the other, at the outer edge of the rectus muscle; and in order to find it the fingers must be pressed down to some little depth. The tumor never subsides suddenly to justify the suspicion of pus or fæces. The tumor feels something like an enlarged lymphatic gland. These cases are very liable to relapse unless the habits, food and drink are controlled with a good deal of strictness.

The treatment is pretty much the same as for enteritis, with some exceptions, however. In severe cases, leeches; in others, opiates with calomel. After the pain has considerably subsided, the use of purgatives seems to improve the disease greatly. In the course of a few days, a two-inch blister, which may be repeated. In old or severe cases, the tumor may remain for a time, with some tenderness, after recovery, in all other respects, has taken place; in this state the external use of iodine, kept up for a long time, may be useful.

BACKWOODS.

London, Ont., Nov. 15, 1887.

NOTES AND COMMENTS.

Herpes Zoster Ophthalmicus.

Dr. Kent K. Wheelock, Professor of Diseases of the Eye and Ear in the Fort Wayne College of Medicine, in a paper read before the Allen County Medical Society, reports the following interesting case:

A. F. K., a German, aged 55 years, and a farmer by occupation, applied for treatment on March 19 of the present year. He is a strongly built man, and seems possessed of great physical strength. When the patient was first seen, he gave evidence of great physical suffering; the cheek and nose on the right side were swollen and glazed; the right side of the nose very red and studded with an eruption, which was circular in shape and covered with crusts having the appearance of being composed of lymph, serum and red blood corpuscles. The supra-orbital region on the right side was red, swollen and glazed, and the region over the course of the supra-orbital nerve very tender to the touch; the region of the supra-trochlear nerve was tender upon pressure; the redness, swelling and pain were confined to the right side of the median line of the head

DIET, IN RELATION TO AGE AND ACTIVITY. By SIR HENRY THOMPSON, F.R.C.S., Surgeon Extraordinary to his Majesty, the King of the Belgians, etc. From the tenth English edition. Small 8vo, pp. vi, 94. Boston: Cupples & Hurd, 1888. Price, 50 cents.

On turning the title page of this interesting and valuable little book, we meet the gratifying statement that it is "published by arrangement with the author." This is the best thing which a high-minded publisher can do under the existing conditions of international law in regard to copyright, and we congratulate author and publishers upon it.

The contents of Sir Henry Thompson's book are such that it is no wonder it has already passed through ten editions in England. It is full of wise suggestions, couched in very pleasing style. Sir Henry is no vegetarian, and speaks with ill-concealed scorn of those who assume this title: principally because it is not an accurate one. He finds fault with so-called vegetarians for eating eggs and cheese, and drinking milk. In this, we think he is a little captious. As he admits, it is hard to find a name which conveniently and accurately describes those who are vegetarians only in the sense that they do not eat ~~meat~~ ^{meat}. The eye were further reduced by reason of the complication of plastic iritis. The patient had suffered excruciating pain, at first almost constantly, but latterly it was paroxysmal. The treatment was local and constitutional. To control the pain, hot applications were made and kept up uninterruptedly for some hours. A cantharides plaster about the size of a silver dollar was put over the distribution of the supra-orbital nerve. To cleanse the eye, a solution of bichloride of mercury warmed (1-4000) was employed every hour; quinine was pushed till its physiological effects were observed, and bromide of zinc and nux vomica were given for their sedative and stimulant action. No new eruption appeared afterwards, but at intervals paroxysms of pain, lasting several hours, came on. To control these, morphia was employed. In about one week the painful attacks became fewer and fewer, finally disappearing. The patient then complained that his eye-ball felt cold, like ice, and that he felt very much depressed and could not keep warm; that hot water did not restore warmth to the eye-ball. The Faradic current was then used to the extent of easy toleration. Immediately the cold sensation passed away, and returned again once or twice, and then only for a short time. After a few applications of electricity sensation returned to the eye-ball, being observed at that part corresponding to the area of pus in the anterior chamber. Returning sensation and thinning and narrowing of the ulcer were about simultaneous. One peculiar effect of the electricity was observed at a certain visit. A small ulcer, the size of two pin-heads, occupied the centre of the cornea, shading off into a general haziness.

After using the current about twenty minutes, one pole applied to the eye-ball through the upper lid, the other to the base of the skull, another examination showed complete absence of ulcerated area, the depression having become filled up, and the cornea appeared bright and clear. The area of sensation at this visit was small before applying the current, but after use of the electricity there were several sensitive points. At this time the author was using electricity twice weekly, keeping up the strychnia.

At his last visit there was still some circumcorneal redness and areas of corneal insensibility. The pupil was then almost entirely occluded with plastic lymph, notwithstanding the free use of atropia.—*Fort Wayne Journal of Med. Science.*

Supplementary Mammary Glands.

Dr. D. C. Holton, of Brooklyn, sends to the *N. Y. Med. Journal*, Nov. 12, 1887, a short account of a case in which, on the third day after parturition, the patient complained of her breasts, for which he gave certain directions as to treatment. At his next visit he was told that the breasts were better, but that "the lumps under the arms" were still hard and painful, and that the patient had to lie with her arms over her head to prevent pressure on them. On examination, he found what at first appeared to be axillary lymphatic glands very much enlarged, but proved, on closer examination, to be supplementary mammary glands. They were situated one at the anterior border of each axilla, each being about as large as a duck's egg and having a small but distinct nipple with a faint areola surrounding it, and milk could be pressed from the nipples. It was the patient's third confinement, and she stated that the "lumps" had appeared with every child.

In the *Edinburgh Med. Journal*, November, 1887, Dr. Hartley Dixon reports the case of a woman having four breasts. About the fourth day after the completion of labor he had occasion to examine the breasts, and noticed a slight swelling below the right breast which was very soft on pressure. A fuller examination revealed the fact that the right and left mammae were fully developed; the nipple of both was very prominent; the areola dark and wide. About two inches below the lower border of the base of the right mamma, commenced the base of another distinct mamma, measuring at its base $2\frac{3}{4}$ inches; the nipple of this one also was distinct, and the areola dark. This became

filled with milk at the same time as the right mamma, and on slight pressure gave the uneven surface which is caused by the lobes and lobules of the normal mammae. On the left side, about the lower border of the tenth rib, was a distinct prominence, with a decided areola, but no nipple. This did not seem to have any connection with the left mamma. The mother stated to Dr. Dixon that her other three daughters had no marks of any kind upon them.

The American Physique.

Mr. Edward Atkinson has a letter in *Science*, November 11, 1887, in which he says: Last spring I received a letter from an English gentleman who is interested in anthropology and biology, asking me if there were any facts to sustain the impression abroad that the white man is deteriorating in size, weight, and condition in the United States. I had no positive information of my own to give, and I could only refer my correspondent to the data of the measurement of soldiers, and to some other investigations of less importance.

It occurred to me, however, that, since by far the greater part of the men of this country are clad in ready-made clothing, the experience of the clothiers might be valuable, and that, from their figures of the average sizes of the garments prepared by them for men's use, very clear deductions could be made as to the average size of the American man.

I therefore sent a letter to two clothiers in Boston who have been long in the business, one in Chicago, one in New York, one in Baltimore, one in Detroit, one in Texas, and one in Montreal. The information received in return is to this effect:

In any given thousand of garments the average of all the returns is as follows: chest-measure, 38 inches; waist, $33\frac{1}{2}$ inches; length of leg inside, $32\frac{1}{2}$ inches; average height ranging from 5 feet $8\frac{1}{2}$ inches to 5 feet 9 in New England, up to 5 feet 10 for the average at the South and West. A few deductions of weight are given from which one can infer that the average man weighs between 155 and 160 pounds.

My correspondent in Chicago states "that, so far as relates to the assertion that the race in this country deteriorates, our experience teaches us the contrary is the case. We are now, and have for several years past, been obliged to adopt a larger scale of sizes, and many more extra sizes in width as well as in

length, than were required ten years ago. Different sections vary very much in those requirements. For instance, an experienced stock-clerk will pick out for South and South-western trade, coats and vests, breast-measure 35 to 40, pants always one or two sizes smaller around the belly than the length of leg inside; for Western and Northern trade, coats and vests, breast-measure, 37 to 42, pants 33 to 40 around the belly, 30 to 34 length of leg inside."

My correspondent in Texas gives the average 38 inches chest, 33 to 34 inches waist, $32\frac{1}{2}$ leg-measure, 5 feet 10 inches height, adding, "We find that the waist measure has increased from an average of 32 to 33 inches during the past five years, and we think our people are becoming stouter built."

My correspondent in Baltimore had previously made the same statement: to wit, "Since the late war we have noticed that the average-sized suits for our Southern trade has increased fully one inch around the chest and waist, while there has been no apparent change in the length of pants."

I asked this firm if the change could be due to the fact that the colored people had become buyers of ready-made clothing, but have for reply that the fact that the negroes are buying more ready-made clothing now than previous to the war, accounts in only a small degree for the increase of the size, but is due almost entirely to the increased physical activity on the part of the whites. The experience of this firm covers thirty-five years.

My correspondent in New York states that "for the last thirty years our clothing, numbering at least 750,000 garments yearly, has been exclusively sold in the Southern States. We find the average man to measure 37 inches around the chest, 32 to 33 around the waist, 33 to 34 inches length of leg inside, average height 5 feet 10 inches. The Southerner measures more in the leg than around the waist,—a peculiarity in direct contrast to the Western man, who measures more around the waist than in the leg."

Possibly the average size for a woman could be deduced from the data of manufacturers of knit goods. From what I know of the business of the clothiers to whom I made application, I should infer that the figures which I have submitted above would cover more than one hundred million garments; and I know of no better method of coming at a rough-and-ready conclusion regarding the size of men, than the one which I have adopted.

Contusion of the Abdomen, with Rupture of the Intestine.

In an experimental and clinical paper on this subject in the *American Journal of the Medical Sciences*, October, 1887, Dr. Curtis sums up the practical results of his inquiry in three propositions:

"1. The treatment of contusion of the abdomen should be purely expectant in the early stage, until symptoms of internal injury have appeared, or until the full extent of time in which they may be expected has passed. Explorative laparotomy at this time is inadmissible.

2. When symptoms of uncontrollable internal hemorrhage or serious visceral injury appear, laparotomy is indicated; but, when the diagnosis is uncertain, the operation should always be begun as an exploration.

3. Great collapse is an absolute contra-indication to all operative interference.

4. When rupture of the intestine is found, the best method of treatment is to secure the injured gut in the abdominal wound and form an artificial anus. This can be easily relieved by a later operation when the patient has recovered his strength."

Regurgitation of Milk Through the Ear.

Dr. H. F. Hendrix, of St. Louis, reports the following interesting case in the *St. Louis Medical and Surgical Journal*, November, 1887.

Eddie J., two weeks old, applied for treatment, because he could not nurse well. On inspecting the fauces, the soft palate was found to be absent, which accounted for the trouble in nursing. The child could not exhaust the air in the mouth sufficiently to cause the milk to flow readily; he therefore had to be fed by hand, and did not nourish well at any time. When he was three weeks old, his right ear began to discharge a thin, watery matter containing a slight amount of pus. This continued for a time, when it was noticed that in feeding, while lying on the right side, milk would flow from the corresponding ear, and some of it coagulated or curdled in the aural canal. Finally, at the age of eight months, he contracted whooping cough. The other ear now began to discharge as the right one had done, and soon the milk began to run from it when the child nursed while lying on the left side. At this time also measles supervened, and subsequently diarrhœa, which was too severe for his feeble constitution, and he died.

Measles followed by Gastric Ulcer and Fatal Hemorrhage.

In the *N. Y. Medical Journal*, October 29, 1887, Dr. Robert Abbe reports a case of measles occurring in a young woman twenty-two years of age, who had previously been in excellent health. At first the attack seemed to be of ordinary severity; but, at the end of a week, it was accompanied by much prostration, a disposition to syncope, rapid wasting, sallow skin, and a striking loss of tone in the skin, which, when pinched up, sluggishly returned to its place. Subsequently the eruption became hemorrhagic. Convalescence was slow, and a "purulent bronchitis" seemed for a time about to degenerate into phthisis. After an absence of two months in the South, she returned apparently in excellent health, but soon developed symptoms of gastric ulcer. One morning, after breakfast, she was seized with pain in the side and nausea, and rushed to the bath-room and vomited about three pints of blood, one pint of which was pure blood. Collapse followed the hemorrhage, from which she but slowly reacted. Twenty-four hours later, when about to receive a nutritive enema, she again vomited; this time altogether about a teacupful and a half. After this second hemorrhage she had three large, fluid, tarry stools. Six days afterwards she developed a parotid abscess, which was opened; the fever, nevertheless, kept up, and the patient died on the thirteenth day after the last hemorrhage.

The autopsy showed, in addition to marked anæmia of all the organs, a stomach which was normal in size and location: the cardiac and pyloric orifices were normal in size and perfectly free. The mucous membrane was smooth and very pale in color. In the posterior wall, six centimetres from the œsophageal orifice, and just to the right of a line drawn parallel to the œsophagus, was an apparent loss of the mucous surface, circular in shape and six millimetres in diameter. In its centre was a hard nipple-shaped elevation, and beside this elevation, extending transversely across the implicated area, was a vessel with thin walls partially filled with blood. There was no elevation of the edges of the area, and by the unaided eye it could not be identified as an ulcer. Microscopic examination of the area showed a total loss of the mucous membrane to the extent of the measurements given above. At the base of this ulcer were seen an artery and vein of considerable size. The walls of the vein were everywhere intact. The hard, nipple-like elevation already described was the rup-

tured wall of an artery. Sections carried along through the entire ulcer showed a rupture of the artery involving one-half of its wall. The other half showed no evidence of disease. A mass of fibrin and blood clung to the ruptured wall, and, for a short distance on either side of the rupture, the wall was split up and contained fibrin and blood. There was a zone of small round cells surrounding the ulcer, and at the bottom the capillaries were filled with blood, and the round cells of inflammation infiltrated the connective tissue. Sections made in other parts of the stomach revealed no lesions of its coats or vessels.

Most cases of "black measles," of which this was an example, are the result of a low grade of catarrhal pneumonia which occurs as a sequel to the attack of measles. It is possible that, in this case, what is described by the author as purulent bronchitis was, or was accompanied by, catarrhal pneumonia.

Champagne vs. Cholera.

In *Littell's Living Age*, Nov. 12, 1887, there is an interesting article, from the *Edinburgh Review*, on Dr. Guillemard's book, "The Cruise of the Marchesa," in which the statement is made that, at Macassar, champagne is supposed to be a good prophylactic against the cholera. At a ball, the foreign guest was urged by his Dutch hosts to drink freely in order to escape the dreadful scourge. "Float the liver, my dear sir; keep your liver floating constantly in champagne, and you will never catch the cholera," was the advice given.

Vicarious Menstruation.

A woman in the clinic of Dr. Buman, of Freiburg (Switzerland), was suffering from a carbuncle which had made its appearance in the lower abdomen. The necrosed tissue was removed about the time the patient should have menstruated. The menstruation did not appear in the usual manner, however, but in the shape of an abundant hemorrhage from the solution of continuity caused by the carbuncle. The hemorrhage lasted three days, and subsided without further phenomena.—*Med. Press* (N. Y.), Nov., 1887.

Lime-Juice Cordial.

The *Chemist and Druggist* gives the following formula for this cordial:

Glucose.....	f5ij
Syrup.....	f3j
Lime-juice.....	f3j
Water.....	f3xiv

Tincture of lemon peel, triple orange-flower water, of each enough to flavor.

NEWS ITEMS.

—Dr. Charles B. Nancrede has been elected Surgeon to the Jefferson Medical College Hospital, to succeed Dr. Richard J. Levis, who recently resigned.

—Dr. V. P. Gibney has been appointed surgeon in chief of the Hospital for the Ruptured and Crippled in New York, in place of the late Dr. Knight.

—The Boston Board of Health has voted to designate all houses in which there are cases of scarlet fever, by the display of a signal, after the manner already pursued in some country districts.

—The *Brit. Med. Journal* says that on November 9th there were 2692 patients in the London Hospitals, including 2539 with scarlet fever, 125 with typhoid fever, and 28 with other diseases.

—The typhoid fever, which caused forty deaths in Cincinnati recently, seems to be abating. The deaths last week numbered only twenty-six, and the number of new cases is diminishing.

—At Exeter, England, a clergyman, who was reading the burial service over the body of a young girl, was so affected by the circumstances surrounding her death as to lay himself open to a false charge of drunkenness.

—The *N. Y. World* says: Many of the leading figures in Continental politics are suffering physical ills. The Czar of Russia is slowly recovering from the measles, Prince Bismarck has the rheumatism, Emperor William, of Germany, has just had a severe attack of old age, the Crown Prince has had an alarming return of his throat trouble, the King of Holland and the King of Bavaria may die at any moment, and the Sultan of Turkey is said to be laboring under severe nervous depression. It is a busy time for Court physicians in Europe.

—The *Lancet* thinks that not the least important part of Sir James Paget's address at Manchester, England, was that in which he spoke of the value of private practice as a sphere for observation of facts, histories and cases extending over long periods of time, and in which successive members and generations of a family of practitioners may take part.

—Governor Hill, on November 19, appointed Mrs. Charlotte S. Williams, of Buffalo, and Mrs. Caroline B. Stoddard, of Rochester, as two of the managers of the State Insane Asylum, at Buffalo, to fill vacan-

cies. There are a large number of female inmates in the institution, and this fact induced the Governor to appoint a majority of woman as managers. The appointments were urged by numerous organizations of ladies.

—The business committee for the coming meeting of the Medical Society of the State of New York, consists of Dr. F. A. Castle, of New York (Chairman), Dr. A. Walter Suiter, of Herkimer County, and Dr. J. W. Whitbeck, of Monroe County. The members and delegates who intend to read papers at the meeting are asked to notify some member of the committee or the president, Dr. Alfred L. Loomis, of New York, before the 20th of December.

—The *Chicago Tribune* states that the farming community near Potomac, Ill., is alarmed over the prevalence of milk sickness, which has assumed an epidemic form. Three persons died last week from the disease, and others are not expected to live. The disease first made its appearance in the family of a man named Doane, the members of which contracted the disease from drinking the milk of a cow afflicted with it. The afflicted locality joins Salt Fork Creek, which has gone dry, and the malady is believed to have been caused by the drouth.

—In his annual report to the Secretary of the Navy, Surgeon-General F. M. Gunnell states that the condition of the medical corps of the navy urgently calls for legislative action. There are, he says, now twelve vacancies in the rank of Assistant-Surgeon. The loss of members in the active list of the corps during the year amounted to nine officers, while only six Assistant Surgeons were appointed. The report shows that the daily average number of sick in the navy was 204.69, the admissions per thousand of mean strength 901.59, and the deaths per thousand 54.4.

—The late Lady Brassey, who became generally known through her book, called "The Voyage of the Sunbeam," was long in such frail health, that most women in her condition would have given up to complete invalidism. She nevertheless took a most prominent part in all social, charitable and literary matters; and in her short life of about fifty years accomplished more real work than most people could do if they lived to be a hundred years old. This was the result of indomitable energy and perseverance, which, as in her case, are not infrequently associated with great brain power and weak lungs.

—A New York wine merchant is given credit to having said: "They make wine nowadays without a particle of grape juice in it. We have just received from Portugal a proposition to supply us with a secret coloring matter. The proposition has it all figured out for us to show that with any amount of their stuff, costing \$13 in our money, we can turn 1650 gallons of white wine into claret. They send a sample with the offer. Just so much of it as could be taken upon the point of a knife-blade turned a glass of water in an instant into the loveliest claret-colored liquid you ever saw."—*National Druggist.*

—The annual meeting of the American Academy of Dental Science was held in Boston recently. The annual address was delivered by T. C. Stellwagon, M.D., D.D.S., of Philadelphia, on "The Inheritance of Mental and Physical Characteristics." These officers were elected: President, Dr. Cecil Wilson; Vice-President, Dr. F. N. Seabury; Recording Secretary, Dr. V. C. Pond; Corresponding Secretary, Dr. E. B. Hitchcock; Treasurer, Dr. E. H. Smith. Executive Committee—Dr. F. O. Loveland, Dr. W. B. Parker and Dr. C. H. Taft.

—The Paris correspondent of the *Medical Press and Circular* reports to that journal the case of a respectable servant, who was ravished by two foot-pads after they had filled her mouth with sand, so that she could make no outcry. At the trial the lawyer selected to defend the villains did so by using his utmost endeavors to prove that the woman was a common prostitute, and hence a very willing victim. Her ravishers were convicted, but the poor woman was so profoundly shocked by the accusations made by the lawyer, that she had to be taken to a hospital delirious, and it is feared may permanently lose her reason.

—While Parisians were enjoying the prospect of a supply of pure water at an expense representing barely the cost of a railway several hundred miles long, Dr. Fontaine-Atgier, of Fontainebleau, now comes forward to remind us that the water of the Lake Lemane is so infested with eggs of the bothrycephalus that the natives get their water-supply at some expense from mountain springs, and carefully avoid drinking the lake water. The helminth, it seems, is harbored by a fish called "Ferra," and readily finds a home in human intestines. Good water, then, must be sought for elsewhere. Those medical men spoil everything!—*Chem. and Druggist*, Oct. 29.

HUMOR.

—A London druggist has hit the popular taste for good bargains. In his window he displays a card that reads: "Come in and get twelve emetics for one shilling.—*Texas Siftings.*"

—*Even Doctors do it Sometimes.*—A Maine physician says that one day he saw a big crane standing on a log that floated near the shore on the Kennebec river. The crane had captured a large bug, which he dropped into the stream, so that it floated down past him, and then grabbed it and again repeated the performance. He kept this up for nearly half an hour, and then a pickerel darted up from below after the bug. This was just what the bird had been waiting for, and the next moment the fish was down his throat, and he was winging his way slowly up stream.

—This conversation occurred at Nottingham:

Lady (with a slight lisp)—"If you please, I want a pennyworth of *doo*."

Chemist—"I beg pardon?"

Lady—"If you please, I want a pennyworth of *doo*."

Chemist (rather perplexed)—"May I ask for what purpose it is required?"

Lady—"I understand it is a good thing to give babies when constipated."

Chemist—"Perhaps you have mistaken the name, and require manna?"

Lady—"Oh, yes. I knew it was something that fell from heaven, and thought it must be *doo*."—*Chemist and Druggist.*

—The New York *Sun* tells a story of a woman who was carrying three leeches home in a street-car from an apothecary's for her sick husband, when one escaped from the box and fastened upon her wrist. Piercing shrieks from the lady called the attention of the passengers to the mishap. One man, unusually bold, went to the rescue and removed the creature, but on replacing it in the box it was found that the other two had also escaped. A general panic ensued, with screams and mounting of seats by the female passengers, each of whom imagined she was wearing one or both of the other two leeches. A semblance of peace was restored only when the missing creatures were found in the matting of the car. Their spirit was broken and their functional usefulness past restoration, but the sick man for whose swollen leg they were intended, on hearing the story, laughed till the swelling went down.—*Med. Herald.*

—*A Clergyman Foiled.*—A clerical-looking gentleman, in the hope of obtaining a contribution, entered the office of a Texas newspaper, and, finding the editor at his desk, said: "I am soliciting aid for a high-toned gentleman of refinement and intelligence who is in need of a little ready money, but is too proud to make known his sufferings." "Why!" exclaimed the editor, "I'm the only man in town that answers that description. What's the gentleman's name?" "I am not at liberty to disclose his name." "It must be me, parson. God bless you and prosper you in your good work," said the editor, wiping away a tear. The editor says that the look the parson gave him as he went out will haunt him to his grave.

—In the village of O—, in central New York, lives a sharp-tongued old bachelor whom I have known for twenty-five years as "Uncle John." Uncle John is something of a character about town, and not destitute of Yankee wit and shrewdness. He used to make and vend in an amateurish way a certain cough mixture, the merits of which he preached to his friends with great enthusiasm, warranting the remedy to cure any cold in twenty-four hours "or no pay." One of his old friends, whom we will call Ike, being afflicted with a severe coughing cold, Uncle John used his best efforts in argument, persuasion, and finally vehement and profane scolding, to get him to try the remedy. But Ike could not be induced to "chance it." Not long after this Uncle John caught a hard cold himself, which was accompanied by a most distressing cough that shook his poor old frame unmercifully. It did not, however, prevent his coming down-town and "settin'," as he called, in Ike's market. The cold hung on for a week or more, and the cough had grown no better. Finally, one day Ike resolved to brave Uncle John's sharp tongue, and tease him a little about his failure to rid himself of the cold, and the following dialogue ensued. You are to understand that Uncle John's replies were interrupted with violent coughing.

"John?"

"What yer want?"

"Got a bad cold, 'ain't ye?"

"Yes; got the wust ever had'n my life."

"Hangs on pretty bad, don't it?"

"Yes; beats all."

Hesitatingly, "Why don't you try some o' y'r cough med'cine you wanted to sell me?"

"I thought mebbe y' was fool 'nough ter ask that question: d'yer s'pose I want ter live forever?"—*Harper's Magazine.*

OBITUARY.

JAMES BENNETT, F.R.C.S.E.

James Bennett, tutor in clinical surgery to Edinburgh University, died on October 19, of consumption of the lungs, at the age of thirty-one years.

W. F. TEEVAN, F.R.C.S.

Mr. W. F. Teevan died on October 22, at Hawkhurst, England, of aortic insufficiency complicated with blindness and insanity. He was educated at University College, London, from which he was graduated in 1858. He subsequently devoted himself to surgery, and particularly to genito-urinary surgery.

DR. H. L. VOGELBACH.

Dr. H. L. Vogelbach, recently resident of Melrose, Florida, died at Green Cove Springs, November 17. He was a native of Philadelphia and a prominent physician. In 1861 he enlisted in the 27th Pennsylvania Volunteers, but, after being promoted to captain, resigned on account of ill-health. In 1878 he came to Florida and located at Melrose. He took an active interest in all public affairs, especially school matters.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Nov. 20, 1887, to Nov. 26, 1887:

Lieutenant-Colonel A. K. Smith, Surgeon, assigned to duty as Attending Surgeon in New York City.

Lieutenant-Colonel J. R. Smith, Surgeon, ordered for duty as Medical Director, Dep't of Dakota.

Major S. M. Horton, Surgeon, granted six months' leave of absence on surgeon's certificate of disability.

Capt. W. H. Arthur, Assistant Surgeon, granted two months' leave of absence, with permission to apply for two months' extension, to take effect on the arrival at Fort Niagara, N. Y., of Assistant Surgeon Paul R. Brown.

First Lieutenant J. R. Kean, Assistant Surgeon, granted two months' leave of absence, to take effect about Dec. 1. S. O. 269, A. G. O., Nov. 18, 1887.

Capt. Paul R. Brown, Assistant Surgeon, ordered to Fort Niagara, N. Y.

Capt. John O. Skinner, Assistant Surgeon, ordered to Fort Ontario, N. Y.

Capt. Charles Richard, Assistant Surgeon, ordered to post near Denver, Col.

Capt. E. C. Carter, Assistant Surgeon, ordered to Willet's Point, N. Y. S. O. 270, A. G. O., Nov. 19, 1887.

List of Changes in the Medical Corps of the U. S. Navy, during the week ending Nov. 26, 1887:

Passed Assistant Surgeon F. S. Nash, detached from duty at the Smithsonian Institute, and ordered to the Washington Navy Yard.

BINIODIDE OF MERCURY AS AN ANTI-SEPTIC IN PUERPERAL SEPTICÆMIA.

BY JOHN J. THOMAS, M.D.,
YOUNGSTOWN, O.

In the month of June, 1885, Dr. Eugene P. Bernardy read before the Obstetrical Society of Philadelphia a paper on the "Value of Biniodide of Mercury as an Antiseptic in Obstetrics," detailing his, at that period, somewhat limited experience with this agent. The reading of the paper brought about an interesting discussion, and one which was participated in by a number of the leaders in obstetrics and gynecology. This was followed by a second paper by the same author upon the same subject, presented to the Society at a meeting held on April 1, 1886, and published in the REPORTER of May 1, 1886. Dr. Bernardy's communications included the report of a number of cases illustrative of the germicidal properties of the biniodide of mercury. The evidence adduced certainly appeared to substantiate every claim made in its favor. Dr. Bernardy regards the biniodide as a better and safer antiseptic than the bichloride, and since there have been reports of disastrous results occasionally following the intra-uterine, or even vaginal, injections of solutions of corrosive sublimate, a consideration of the claims of a rival agent, and one appearing to be free from objectionable features, is one that may well occupy our closest attention. This matter

has not received more than a very small fraction of the attention to which it is entitled. None can dispute the anæsthetic properties of sulphuric ether; and none will deny the germicidal potency of the bicloride of mercury. Yet we are in need of a more convenient anæsthetic than ether, and a safer and less irritating antiseptic than the corrosive chloride. The latter, I think, we have already found, but it is unaccountably slow in obtaining recognition.

Since reading Dr. Bernardy's papers, I have availed myself of a number of opportunities of testing the correctness of his views upon the subject, with the effect of leading to a hearty endorsement of the same. I shall point to but one case in detail, alluding in the briefest manner to the case of a multipara, who did well until the eighth day after delivery, when the lochia ceased and the temperature suddenly shot up to 105° , and whose condition in no wise improved after injections of a one in 2000 solution of corrosive sublimate, but who was speedily placed on the way to recovery after the biniodide was resorted to. I shall simply mention the case of a primipara of the age of thirty-nine years and six months, whom I delivered without forceps, and whose perineum, quite contrary to my expectations, suffered no laceration, but who, upon the fourth day, experienced a chill, with high temperature, cessation of lochia and abdominal pain and tenderness, and in whom injections of a solution of biniodide brought about—and that right quickly—an opposite state of affairs, which led to her ultimate recovery. Space will not permit of a full report of these and other cases, which illustrate the

point I desire to make, but I shall ask attention to the details of a peculiarly obstinate case of puerperal septicæmia, the subject of which is not yet out of the bed, but who, I believe, has every prospect of recovery at an early date, a consummation which I shall be disposed to place, when it comes about, to the credit of the biniodide of mercury.

On October 24th of the present year I attended Mrs. T., aged 24, in her third confinement, having attended her myself upon the two previous occasions. The placenta and membranes came away intact, and as the patient was a woman of good constitution, I looked for none other than a good recovery. The after-pains were severe, and for their partial relief moderate doses of opium were used. Upon the second day I noted a rather frequent and somewhat irritable pulse, and soon a rise in temperature was detected. The lochia ceased, and abdominal pain and distension was added to the symptoms. Poulitices and turpentine stupes were applied, quinine and morphia were freely administered, and the uterus washed out with biniodide solution. The temperature fell to nearly normal, and the other symptoms abated to such a degree that, as far as I can recollect, but one more injection was called for (and that to combat a sudden rise in temperature) until Sunday morning, October 30th, when I found a pulse of 140, and temperature of 105°, the patient complaining of having had a "weak spell." Immediately upon entering the room I was struck by the markedly icterode hue of the countenance. I feared embolism, and gave spirits of ammoniæ arom., with digitalis. Fearful of trusting to the biniodide, and knowing of the popularity of the bichloride, I washed out the uterus with a 1 to 2000 solution of the latter. This was at 11 o'clock A.M. On returning at 5.30 P.M., I found the pulse 120, the temperature still 105°. The uterus was then thoroughly irrigated with a solution of biniodide. Next morning (Oct. 31) pulse, 90; temperature, 109°. Evening, pulse, 110; temperature, 102°. Injection, biniodide.

Nov. 1. Morning, pulse, 92; temperature, 99°. Evening, pulse, 120; temperature, 103.5°. Injection, biniodide.

Nov. 2. Morning, pulse, 112; temperature, 103°. Used same injection. And upon returning in the evening found a pulse of 104; temperature, 101.5°.

Nov. 3. Morning, pulse, 76; temperature, 99°. Evening, pulse, 80; temperature, 99°.

Nov. 4. Morning, pulse, 84; temperature, 99°. Evening, pulse, 116; temperature, 104°. Another injection.

Nov. 5. Morning, pulse, 96; temperature, 100.2°. Evening, pulse, 84; temperature, 99°.

Nov. 6. Morning, pulse, 76; temperature, 99°. Made no evening visit.

Nov. 7. Morning, pulse, 88; temperature, 100°. Evening, pulse, 96; temperature, 101°.

Nov. 8. Morning, pulse, 108; temperature, 101.5°. Gave an injection. Evening, pulse, 104; temperature, 102.2°.

Nov. 9. Morning, pulse, 96; temp., 100.5°. 6 o'clock, P. M., pulse, 84; temp., 101.1°. Was recalled at 9.30, P. M., and found a pulse of 120; temp., 105.8°. Washed out the uterus thoroughly with solution of biniodide, using a quart and a half of the fluid.

Nov. 10. Morning, pulse, 100; temp., 102°. Gave another injection. Evening, pulse, 98; temp., 101°.

Nov. 11. Morning, pulse, 88; temp., 100.6°. At this point, my supply of tablets of biniodide having become exhausted, I washed out the uterus with a 1 in 3000 solution of bichloride, the operation causing pain and a feeling of faintness. Evening, pulse, 88; temp., 100.2°.

Nov. 12. Morning, pulse, 80; temp., 100.2°. Used another injection of bichloride. Made no evening visit.

Nov. 13. Morning, pulse, 90; temp., 99.8°.

Nov. 14. Morning, pulse, 90; temp., 100°.

Nov. 15. Morning, pulse, 80; temp., 99.2°.

This brings the case up to the date of writing, where I feel safe in dismissing all apprehensions with regard to the final issue.

It will be seen that the injections were, in nearly every instance, followed by a most decided lowering of the temperature, the most signal instance of failure being that ensuing upon the use of bichloride on Sunday, Oct. 30. Moreover, I found the latter to cause pain and faintness. The biniodide never gave rise to any such symptoms. The tablets used were those prepared by Parke Davis & Co. They contain one grain of mercuric iodide. For intra-uterine injections, the proper strength is one tablet to one and a half pints of water. A solution of this strength does not convey the metallic feeling and impression which is imparted to the hand when immersed in a 1-2000 solution of bichloride. The difference in the toxic effects of the bichloride and biniodide of mercury may be attributed to the probable greater affinity of the former for the living tissues, some of the chlorine compounds forming the natural constituents of the animal organism. The iodides, being foreign to the system, are not so readily absorbed, and their effects are more apt to be spent locally.

The case I report was unquestionably one of septicæmia. It began with a distinct chill. The lochia were very offensive in odor. The skin of the patient was jaundiced in hue. There was vomiting and a tympanitic condition of the bowels. The temperature record is wholly inconsistent with any other condition than one proceeding from successive absorptions of putrid matter. It is unique as regards its duration, and illustrates the safety of repeated washing out of the uterus with a proper mercurial solution. After the first week, this operation becomes increasingly difficult, and perhaps dangerous, of performance. The last injection was given on the nineteenth day after delivery. The manner of its employment was as follows: For the first seven or eight days, the os uteri being sufficiently patulous, I had no difficulty in inserting a plain piece of rubber tubing. Involution proceeding, the os became more firmly closed, necessitating the use of a more unyielding instrument. Over one of the smaller nozzles of an Alpha E continuous flow syringe I slipped a French soft rubber catheter. The latter I pierced with a piece of stiff wire, which was run past the eye-hole to the extremity. Some little resistance was encountered, more particularly at the os internum; but the tube was passed until felt free within the uterine cavity. The wire was then withdrawn and the injection administered by slow and steady pressure upon the bulb. The fluid was felt to return promptly, forcing its way between the tube and the margin of the os. This method I believe to be as convenient and effective as any that can be devised. Simple vaginal injections are at best but a partial attempt at carrying out the idea of striking at the root of the trouble. If it shall prove that the biniodide of mercury is so much safer than the bichloride, no one need fear to undertake thorough irrigation of the uterus in all cases which present symptoms of septic absorption.

There is at present no subject in midwifery which rivals in importance that of antiseptics. Nay, in all the domain of medicine and surgery, there is no theme which can so deservedly engross our attention as this one: shall we, or shall we not, treat the recently emptied womb and its approaches upon the general principles recognized in the modern treatment of traumatism in general? If so, we are in need of a reliable antiseptic and germicide, one that can be used in solution of such strength as shall be effective, and yet harmless to the patient. The bichloride of mercury is poisonous to micro-organisms, but

its use is not entirely free from danger. The biniodide appears to be a reliable germicide. It is claimed to be as effective as the other in solutions of less than one-third the strength. Accumulating experience is leading me to place much reliance upon it. As before stated, in addition to the case reported above, I have had, upon a number of occasions, experience similar to that narrated in Dr. Bernardy's second paper; but I regarded the evidence, while admittedly striking, as inconclusive. The experience of the past three weeks has greatly strengthened my confidence in the antiseptic under discussion; and I feel moved to urge upon my professional brethren a thorough trial of that which I fully believe to be one of the most reliable antiseptics yet discovered.

ELECTRICITY AS A MEANS OF INFLECTING THE DEATH PENALTY THROUGH PROCESS OF LAW.

BY WILLIAM R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

The Book of books tells us that "whoso sheddeth man's blood, by man shall his blood be shed." In pursuance of this edict murder has in all ages been punished by death in almost every portion of the habitable globe, and usually by means of unnecessarily painful and repulsive judicial procedure. Of the many methods employed, hanging by the neck, or strangulation, is at once the most brutal, the most cruel, and the most degrading in its influence upon the spectators of an execution, and there is no real proof that it is in any way a merciful means of destroying life so far as the unfortunate criminal is directly concerned. The object aimed at by most hangmen is to fracture or dislocate one of the vertebræ, at or near the axis or atlas—the highest point of the spinal column; and it is popularly believed that when this effect is attained by a suddenly arrested fall of the body—the arrest being made through the rapid take-up of the slack purposely left in the pendent rope, and ending in a sharp jar—then sensation is instantly destroyed, and death ensues either because of shock, or, as usually happens, from slow choking.

It was my painful duty, during our civil war, to act as medical inspector in fourteen executions by hanging, and at other times I have had more experience in the same capacity, these cases occurring under the ordinary judicial procedure of the courts. Every

care was taken in all instances thus coming under my notice to cause cervical displacement, and in the majority of them the desired effect was secured. I watched carefully in each the progress of life-extinction, and noted critically the pulse rate, the number and force of respirations, and the ordinary evidences of presumed suffering as indicated thus, and by struggling while life remained, and the injury sustained of non-fatal character, shown by post-mortem examination.

In not one of thirty cases was life instantly terminated, and in not one of them was I satisfied that death was painless or nearly so. Rather was it evident that suffering did exist, and in not a few the indications of such were patent to all onlookers, lay and professional alike. My opinion as to the existence or absence of agony is of course as above noted, a meagre quantity in the question; but that my observations are not imaginary is sustained by a number of reports and opinions given to me by high sheriffs, public executioners and physicians, who have had experience in such numbers as to render their testimony of considerable weight, popular belief to the contrary notwithstanding.

Moreover, I have interviewed, to the extent of half a dozen, persons who were accidentally or by attempted suicide nearly strangled, but who recovered, and all of such people testify that hanging is not an easy method of despatching one's self.

In my early professional days the unexpected assault from behind on myself of a maniac, who grasped me by the throat and nearly succeeded in strangling me before assistance arrived, gives me a vivid experience, and from it I would not choose "*sus. per coll.*," if I had to choose any method other than that which is the unknown medium of our transfer to the great hereafter.

I have thus far referred only to hanging as a cruel form of terminating human existence, and a very few words will cover the question as to whether or not a better method is now accessible, and one that is free from the horrible paraphernalia of the gibbet. In civilized lands two plans of hanging are employed—the one permitting the condemned to fall through a trap until the rope checks the descent, and the other jerks the culprit up by the neck from the ground consequent upon the fall of a heavy weight attached through pulleys to the further end of the cord forming the noose. The first method usually results in choking the person—the second in dislocating the neck, or, as occasionally has re-

sulted, in tearing the head from the body. Of course either termination is fatal—the end of justice is attained; but nevertheless the general consensus of opinion amongst Christian people is that in all its surroundings hanging by the neck is cruel, degrading, and barbarous.

The bowstring is merely a differently managed noose, only mentioned to be condemned. The guillotine, although rapid and merciful, would not now be accepted in America, at least, as a substitute for the present method, and none of the other plans advocated or practised by foreign powers would admit of discussion profitably.

If, then, a new means of complying with the law's penalty is desirable, and a decided belief obtains in the land that such is the case, what procedure will at once be available, sure, and humane in accomplishing the desired result? I claim that in electricity we have a solution of the problem. Nothing new about this, of course—the agent has been advocated before for the purpose; but the details of the employment have been cumbered with unnecessary machinery, sensational trappings, and the method of utilizing the current has not, so far as my observation extends, been as efficacious as it can be made.

Since electric lighting has come into common use numerous accidents have been reported in the daily papers, but very many more have occurred of which the public knows nothing. The fatal accidents are those which attract attention, and these are incurred principally by linemen who in altering or repairing circuits feeding arc-lamps receive a part or the whole of the current carried by the wire which they are manipulating. In these instances the charge is usually thrown across the chest and arms, and a part more or less forcible is transferred by the clothing, the quantity depending on the dampness of the attire, which ordinarily consists largely of heavy woollen underwear readily retaining perspiration or wetting from exposure. A number of instances are known to me in which a forty light current of sixteen hundred volts and eight amperes was apparently driven directly through the thorax, yet the man escaped with severe burns only, and in some cases the shock was not profound. Investigation proved the major part of the charge to have gone across by wet clothing, hence the escape from loss of life.

During the last twenty-five years I have been a close student of electricity in its application to therapeutics, and in its employment for the many purposes to which it is

now put in daily business. Many experiments have been made with varied ends in view, and amongst these I have tried to learn in what way electric force might best be utilized in terminating life, when such an end was desirable or justifiable. These experiments were made on living animals of many kinds, some of them smaller in size and weight than mankind, and others greatly larger and heavier than ourselves. The known varying tenacity of life, also, was noted as a factor in the series of investigations. Currents from galvanic, Faradic, and static electric apparatus were employed; and the Faradic mechanism comprised the ordinary coils actuated by galvanic cells, and those energized by permanent or electro-magnets. The arc-light dynamo was frequently used. In order to disarm any critics who may discover an inconsistency in my present position as an anti-vivisectionist, with the confession that I made these investigations, I state: first, In all instances the animal was killed instantly by the charge; second, In those cases where doubt existed as to whether or not the force would be powerful enough to destroy vitality, full anæsthesia was practised before electricity was used. No dissection, and no surgical procedure of any kind or degree was employed throughout the entire series; in short, no *vivisection* was perpetrated on a solitary animal. In nearly all instances autopsies were made; but all mutilation, surgically, was done post-mortem, not ante-mortem.

The results of this work, coupled with experience gained in medical practice, together with the lessons learned from accidental deaths by lightning-stroke and fatal contact with modern dynamo-electric currents, coming under my notice, has shown that to my mind the human body can receive with apparent impunity about three hundred volts, so far as possible escape from fatal results are concerned. Of course a current of this potential is dangerous to life, and undoubtedly severe injury will usually result from unguarded contact with it. Everything depends in case of accident upon what part of the body sustains the injury, and it is certain that a charge which, though fatal to life when sent through the cerebro-spinal axis, might be borne without death ensuing if confined to the inferior limbs; and possibly, also, in some persons, when sent across the spinal cord around the thorax and through the superior limbs. That this is so is proved by cases known to me of injury from arc-lighting machinery terminating in recovery in some, but with others in death, the charge

encountered being practically the same in the different individuals. My experiments proved to my satisfaction, also, that lower charges were needed to kill, provided they passed through the abdomen, than those affecting the thorax, owing to the destructive effect upon the sympathetic system of nerves. Upon this finding I base the method, which will later be proposed, of utilizing electricity as a means for destroying life.

Cadaveric section has shown, that in death from lightning, the blood is rendered unusually fluid; the muscles and nerves lying in the path of the current are more or less torn at points; important viscera are also generally ruptured.

When a current of high potential is diverted through the human body, the effect is that of breaking the circuit in the conductor for an instant of time. When breaking or reversal of an electric current occurs, the phenomena known as "the extra current" is developed at the switch, controlling the operation. A human body suddenly intervening itself, or participating itself largely in the continuity of a metallic electric conductor, even though it does not divert or convey the whole charge thereon carried, acts the part of a switch for the time being, and it is the extra current then developed at the contact point and received by the person that does the most harm, although the main current may of itself be sufficient to kill.

A current of six hundred volts or more, passed through the cerebro-spinal and sympathetic system in the manner now to be described, will, beyond doubt, destroy life instantly, and, so far as human knowledge goes, will do so without pain.

A collar, adjustable to the neck of the person, has upon its inner posterior aspect a metallic disk, which, when applied, presses upon the cervical spine. On each side laterally are similar disks, which, when in position, cover the pneumogastric and the descendens noni nerves, with the great blood-vessels of the neck close below the plexus gangliformis. A belt encircling the abdomen just below the sternum holds a disk similar to those of the collar, but of double their size. This plate is placed over the solar plexus (just below the lower end of the breast bone or upon the pit of the stomach), and now the spinal and sympathetic systems intervene between the poles, one of which (the positive) is attached to the collar, and the other (the negative) to the abdominal band.

A simple modification of the ordinary reversing switch common to electric mechanism, permits the current to be sent through

the circuit described, a continuation of the lateral movement of the device reverses the direction of the flow, the duration being governed by the time taken in moving the switch from point to point.¹ A current of the intensity named (six hundred volts or more) thus manipulated immediately tetanizes the entire muscular system to such a pitch that disintegration occurs, not alone in the direct path of the moving charge, but at far distant points, because of the diffusion of the current which always obtains under high power. The nerve trunks, also, to their minute ramifications, are disrupted; and the brain, though somewhat beyond the points of entrance and exit of the current, is broken up into a pulpy mass. The blood is rendered unduly fluid.

To place the matter beyond doubt in reference to the physical action upon the human body, I have submitted the dead subject to experimental trials with the results above noted. That which takes place in the recently dead human body is precisely similar to that obtained in the living subjects of the lower animals, hence we are justified in stating that like results must be had when man is substituted for the brute. Under electric death decomposition ensues rapidly.

The great progress made in electric lighting recently has made the arc-lamp a necessity in almost every town throughout the land. Sure it is, that the time is near at hand when this illuminant will be a part of the fittings of all public buildings, and the jails will be peculiarly appropriate places for its employment. Even were the light not used, a loop is readily run in from the street circuits to a chosen cell or location within the prison, and the simple apparatus would always be ready for use, even by unskilled hands.

Much mental suffering might be saved the condemned by administering in the evening meal, previous to the day of execution, a strong narcotic, and the little preparation needed of the person could be made whilst in a state of torpor or unconsciousness, more or less profound, as required or desired.

The method proposed would not preclude the attendance of a jury or in any way conflict with such necessary ceremonies as now prevail; it would fulfill the intent of the

law, and it would abrogate a present procedure at once horrible to contemplate, and often uncertain, because of bungling officials; substituting therefor in the future an action free from spectacular display, and humane, so far as may be in the light of the growing humanity of the nineteenth century.

ALCOHOL AND ITS USES.

BY H. A. HARE, M.D. (UNIV. OF PA.)

Demonstrator of Experimental Therapeutics, and
Instructor in Physical Diagnosis in the
University of Pennsylvania.

The writings *pro* and *con*, in regard to the use of this remedy and its real value, would, if brought together, produce such an encyclopædia of alcoholic literature, that even a prohibitionist might tremble before beginning its analysis.

In this paper no attempt will be made to sum up the conclusions drawn by either party of extremists, but an endeavor will be made to show that alcohol is to be employed in moderation in many diseased conditions in which no other drug is of any corresponding value. Those who are especially interested in this matter will find in the *Boston Medical and Surgical Journal*, July 10 and 17, 1887, a masterly consideration of the whole subject, which points out some of the fallacies found in many of the arguments of those who inveigh against the use of alcohol in medicine. A review of the latest literature concerning the matter, brings irresistably to the unbiased mind the conclusion that alcohol must be considered a useful and constant storehouse of energy when the vital powers flag. Experimental research has, as every one knows, proved that alcohol decreases bodily temperature, and that animals and persons exposed to intense cold, when alcohol is given, succumb much more rapidly than those who do not take the drug.

That a loss of bodily heat is not due to the failure of its production, as much as to the increase in its dissipation, has also been proven. Increased heat dissipation takes place from the fact that, normally, exposure to cold contracts the tissues on the periphery of the body, and drives the warm blood to those organs whose vitality depends on a certain temperature, and to the central core of the trunk where the skin, muscles and connective tissues act as non-conductors; whereas, under the influence of alcohol the blood is driven by the cardiac stimulation to the finger tips, and brings a glow to the surface with a corresponding loss of heat from the interior

¹ The action involved on moving the switch is first to close the circuit or turn on the current—break it—reverse its direction; and on again moving the switch back to its original position, the current is broken—reversed—broken, and turned off. Drawings of the apparatus have been prepared, but its simplicity obviates the necessity for introducing them.

parts. The man must manufacture, therefore, more heat, more oxidation of tissue must take place, and his vital force is consequently impaired. To say from this, that alcohol is a remedy of a dangerous character for all depressing diseases, is lacking in a true knowledge of its effects; for, unless the surrounding atmosphere is very cold, the slight increase in heat dissipation is more than counter-balanced by the force added to the system. Alcohol has been proved by many observers to support the system and to aid the patient over some ditch of death into which he might fall, save for the outstretched hand of the drug. No less a chemist than the famous Liebig classed it as one of the foods, not as one which added nutrition to the patient, but which added force.

A very large part of the profession believes that the mere presence of an abnormally high temperature counter-indicates the use of alcohol. Mere high temperature does not do so, however, and it seems probable that many deaths have resulted from putting into practice such belief.

High temperature of a sthenic type, with a full, tense, bounding pulse, and all the signs of a disease attacking one in the full vigor of life, of course precludes its use; but in the high temperature of advanced typhoid, with the marked asthenia often present in that stage, alcohol should be given constantly in large amount. Under these circumstances the tissues which the man can afford to lose are gone, and much of the vital portion of his system is greatly encroached upon; the alcohol yields force to the body, is then burnt up to a great degree, and keeps the flagging heart pumping the tides of blood through the lungs and systemic circulation, when otherwise the very cardiac depression would produce hypostatic congestions, if not more widespread consolidation.

A no less useful and valuable result obtained by the use of alcohol in the early stages of exhaustive fevers is the part that it plays in aiding digestion. I have already, in another paper, defined the difference between the influence of alcohol in the artificial digestion of the test-tube and that occurring in the stomach. No one doubts that alcohol, added to a small amount of gastric juice in the test-tube, retards or prevents its action; but evidence is abundant to prove that the ingestion of this drug into the stomach produces a very decided increase in the quantity of gastric juice excreted over and above that normally present, by its stimulating and irritant action. Aside from experimental evidence, everyday experience has taught the

gourmand that alcohol, in some form of a fairly concentrated degree, enables him to digest an amount of food which under ordinary circumstances would remain unchanged in his stomach.

Alcohol should, therefore, be used all through the ordinary exhausting fevers, for the purpose, in the first stage, of aiding digestion, and, in the later stages, of supporting the system.

The importance of aiding the flagging powers of the stomach is not generally recognized; but if one remembers the fact that, at one time during the course of a severe attack of typhoid, an occasion must come when a struggle between the few remaining grains of strength and the disease results on one hand in death, or in recovery, its importance becomes evident. By the ingestion and *digestion* of more food early in the attack, a larger amount of vital force remains for use at the crisis, and the chances of a recovery, to say the least, are increased.

In those cases with a temporary loss of heart power, due to hemorrhage or some sudden, severe depression, alcohol is, above all others, the remedy to be employed, hot and concentrated. The same conditions make it, with ammonia, a most useful remedy in snake-bite; where the fugacious action of the ammonia is followed by the more permanent stimulation of the alcohol.

That alcohol may be misused, and cause great harm, is of course known to every practitioner of medicine. So long as it reduces the temperature and lowers the rate of the pulse, causes a moistened skin and tongue, and quiets nervous twitchings, it does good; and only up to this point is it to be employed. If its administration is pushed after this, the tendency to adynamia becomes, under the over use of the drug, one of dynamia; the pulse, no longer soft, but full and strong, rushes along the vessels with angry, bounding beats; the nervous symptoms change from low, weak, muttering delirium, with subsultus tendinum, to wild, incoherent callings and strong tossings to and fro; and by and by, when the influence of the alcohol begins to cease, and even before this time, the system has put forth the strength of days in a few hours, and the man is dead.

To deny the use of alcohol, as has been done in the columns of this journal within the last few months, and to assert that it does more harm than good, only shows that persons holding such opinions have gained them from fallacious or illogical reasoning, or, not understanding the proper use of th

drug, they have obtained untoward effects, such as those mentioned.

The moral standpoint of the subject is, so far as therapeutics are concerned, a side issue. Called to a patient in typhoid, our duty is to treat his present condition, not his future one; and we are called to save his life, not to question as to effects of our treatment on his eventual moral tone.

Of course, if one can find a remedy of corresponding action, without the danger of inducing a "habit," well and good; but where does such a one exist?

SULPHURIC ACID POISONING.

BY DR. GEORGE DOCK,

Assistant Physician to the Medical Dispensary of the University Hospital, Philadelphia.

In the very interesting study of suicide, no chapter is more curious than that of fashion in the selection of the means of death. Thus, in Berlin, drowning and hanging are not looked on with favor, especially by those who form the largest number of aspirants for death—servant girls. The stringent laws regulating the sale of poisons, in the ordinary sense of the term, render the use of less unpleasant poisons very restricted, so that common sulphuric acid, the "oleum" of the Berlin housewife, which is used by her for cleaning windows, is often the most accessible, not seldom the only, lethal agent which the would-be suicide can find. The writer has seen several cases of "oleum" poisoning in Leyden's clinic, and there learned its mode of use. As said above, most of the suicides are servant girls, driven to desperation by the absence of menstruation. They can be divided into two classes, according to the time at which the draught is taken, and this again determines the result of the attempt. As put by Prof. Litten, "the girls vex themselves over their condition," and some, with less endurance or more decision, seek the "oleum" bottle at once on rising. Almost always perforation of œsophagus and stomach with speedy death is the result in such cases. Others worry along until after breakfast, but soon after taking that follow it up with the acid. In these cases, even when notable quantities have been taken, recovery can and often does ensue, the acid not coming undiluted in contact with the empty stomach walls.

In the *Charité Annalen*, xii, p. 183, 1887, Dr. Mendelssohn reports the cases of poisoning observed in Leyden's clinic during

the past year, and, as usual, there were a number of cases of sulphuric acid poisoning. Two of Mendelssohn's cases deserve special mention. The first was that of a servant girl, aged 23, who took a moderate quantity of oil of vitriol. After the first severe symptoms had passed by a condition similar to that in simple ulcers of the stomach came on, and at the same time the patient became affected with typhoid fever, to all appearances acquired in hospital. In the fifth week marked improvement of all the symptoms was noted. Vomiting ceased, strength increased, but in the sixth week vomiting began again, and positive symptoms showed that the pyloric passage must be narrowed to the utmost. Resection was performed, but was followed by death in twelve hours in collapse. The pyloric stricture was so severe that only the finest sound could be passed through it. Almost the whole mucous membrane was destroyed.

The second patient had similar symptoms in the beginning, but recovered, and was alive one year afterwards. During the first months no traces of hydrochloric acid could be demonstrated in the gastric juice, though this gradually was found present in its normal amount.

SOCIETY REPORTS.

BRITISH GYNÆCOLOGICAL SOCIETY.

First Meeting, October 12, 1887.

DR. G. GRANVILLE BANTOCK, President, in the chair.

DR. MANSELT MOULLIN showed a specimen of hæmato-salpinx which he had removed from a young married woman aged 25. She had had one child two years previously. In the recent state the tumor was about the size of an egg, constricted in the middle and filled with blood-clot. The chief symptom had been a constant aching pain in the lower part of the back and around the pelvis, from which the patient had been unable to obtain relief in any position, sitting or lying. The pain was also much increased on defecation. The attached ovary was apparently healthy, and the appendages on the opposite side seemingly so, and were allowed to remain. Numerous adhesions were broken down, but no drainage tube had been required. The patient had made a good convalescence, and was now free from pain.

DR. BEDFORD FENWICK said that menorrhagia was usually a symptom in all inflam-

matory diseases of the Fallopian tubes. It was of great importance to remove the cyst without rupturing it, a matter of some difficulty in the present instance, and he thought the operator was to be congratulated on the successful result of a very unpromising case.

MR. LAWSON TAIT was amazed at a recent paper by Mr. Barton, of Liverpool, in which he asserted that such cases as that belonging to the preparation exhibited by Dr. Manselt Moullin, ought under no circumstances, to be touched. Why should a woman with the symptoms just described be obliged go on living the life of an invalid, with a perfectly useless organ inside her, an organ which could never by any possibility resume its original functions, any more than a woman with a cataract in her eye being prevented from having her sight restored by the removal of a useless lens?

DR. ROBERT BARNES presented a dermoid cyst of the ovary. He had removed it a month previously from a woman about 50 years of age. She had suffered intense pain in the pelvis for several years, disabling her from active life, and exhausting her strength. There was a tumor in Douglas's pouch the size of a small orange, movable and firm. The uterus was of normal size. Its position and differentiation from the tumor was determined by the sound. Before submitting to operation, the patient under other advice went through a course of massage, which of course did no good. She made a good recovery from the operation. Dr. Barnes had known at least one case in which a fatal issue had occurred from injudicious massage in abdominal disease.

MR. LAWSON TAIT said that small dermoid tumors of the ovary generally gave rise to the most intense pain, a fact for which some reasonable explanation was required. It was extremely difficult to diagnose between them and disease of the tube. Perfect accuracy of diagnosis in pelvic disease was not possible in the most skilled and experienced hands.

DR. HEYWOOD SMITH considered the pain to be due to pressure upon the contiguous nerves. A tumor that rose into the abdomen usually caused but little pain. The amount of pain had to be considered when giving an opinion as to the advisability of operating.

DR. J. ST. CLAIR BOYD described a case of pseudo-hydramnios, in which the superabundance of fluid did not as in ordinary cases of hydramnios take origin in the membranes, but had its source from an aperture in a hydrocephalic head. The patient, aged 42, had had six children, and thought herself pregnant again, but her enormous size

seemed inconsistent with that view. She was suffering from enormous abdominal distension, dyspnea, and dropsical effusion of the lower extremities. On making a vaginal examination the os uteri was found dilated to the size of a silver dollar, and the bag of membranes protruding from it. On rupturing this thirty pints of fluid escaped. The child was subsequently delivered with the short forceps. The placenta was adherent and had to be removed. The uterus was then injected with a hot solution of hydrarg. perchlor., 1-2000. No hemorrhage occurred. On the third day all trace of dropsical effusion had disappeared from the patient's lower extremities. The child, which was born at the seventh month, had an immense hydrocephalic head. The fluid apparently exuded below the occipital eminence, at which part the skin had become wrinkled owing to the escape of the fluid.

DR. BEDFORD FENWICK said the interest of the case centered in the fact that a distinct fistulous opening existed, otherwise the child's head might have been punctured with and through the uterine membranes. Then the case would have been much simpler and exactly on a par with his own experience.

DR. AVELING had seen cicatrices on the surface of a hydrocephalocele which proved that these cysts ruptured in utero and discharged their contents.

DR. CORDES, of Geneva, gave notes of a case of monstrosity, under his care at La Misericorde Maternity. The cranial vaults were represented by a fibrous membrane. On the left side, through an opening as large as a crown piece, the cerebral substance protruded covered only by the arachnoid and the pia mater. Feet and hands were malformed, and many of the fingers and toes rudimentary. The monstrosity, which was attributed to maternal impressions, lived 6 days.

The following gentlemen were elected fellows of the British Gynecological Society at the meeting of October 12, 1887:

Dr. Harry Frederick Marley, Pedstow, Cornwall; Dr. Thos. J. Hitchens, Crawley, Lassat; Dr. J. St. Clair Boyd, Co. Down; Dr. G. H. Balleray, Paterson, N. J., U. S. A. The following were proposed for election: Dr. James Oliver, London; Dr. Wm. A. Bowen, Rangoon, Burmah; Dr. C. N. Dixon Jones, Brooklyn, N. Y.; Dr. Joseph Price, Philadelphia; Dr. Daniel Mowat, London; Dr. Thos. Kilner Clarke, Haddersfield; Dr. E. A. Spilsbury, Toronto; Dr. Thos. Owens, Ontario; Dr. Geo. Albert Hethrington, St. John, Canada; Dr. Geo. A. Rae, Devonport; Dr. T. Beadman, Duffield, Yorkshire.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, November 3, 1887.

The President, T. M. DRYSDALE, M.D., in the chair.

DR. ROBT. H. HAMILL reported a case of

Puerperal Malarial Fever, Simulating Sepsis.

In the *Amer. Journ. Obst.*, April, 1880, Dr. Fordyce Barker called attention to a peculiar febrile derangement, known as puerperal malarial fever. It is of paramount importance to the obstetrician to know whether or not he has to deal with a disease which is the result of carelessness, or one of miasmatic origin. The following case seemed to be caused by a miasmatic influence. Only the most prominent points in the case will be given, which were as follows: The patient was delivered by version of a premature still-born child, labor being complicated by placenta prævia. Twelve hours after labor had ended the temperature rose to $101\frac{1}{2}^{\circ}$ F., but the patient was otherwise in good condition. The following day her temperature had fallen one degree. In the evening of the third day she had a severe chill, lasting fully twenty minutes, which was followed by fever and profuse sweating. From the nature of the labor, Dr. Hamill feared he had a case of sepsis to deal with; but after learning that during her pregnancy she had suffered considerably, at times, from an ill-defined feeling of lassitude, and "an aching of her whole body;" and further, that in the street on which she lived there were stagnant pools of water, he felt much relieved. In addition to this history, and much to his delight, the woman had another severe chill, followed by the fever and sweating stages. These chills continued to occur daily until the 9th day, decreasing in severity each day. At times there was slight delirium. There was no pelvic pain or tenderness, and little if any tympany; nor no odor to the lochia, which were normal in quantity. The vagina and appendages were perfectly healthy. The blood was not examined, because quinine had been given from the first. Very little change took place in her condition until the 17th day, when there was an abatement in all her symptoms, and convalescence was very rapid. The treatment consisted chiefly in the administration of large doses of quinine and stimulants. In one dose she received thirty grains, followed in two hours by thirty grains more. Quinine seemed to have no effect until used in the form of Warburg's tincture, notwithstanding it had been given

in one large, and in smaller, oft-repeated doses. After the patient began to convalesce, she did not have an unfavorable symptom, and is now fully recovered.

DR. J. L. LUDLOW said he had succeeded in having an exact preparation of Warburg's tincture made by a druggist of this city, and it had yielded him results far better than he could obtain with quinine or any other combination of it. He had used it at Eddy-stone with great success.

DR. DRYSDALE had had wonderful effects from Warburg's tincture.

DR. B. C. HIRST, in speaking of

Catheterization of the Ureters,

reported a case of a patient in the Maternity Hospital, who was a young primagravida, and had pus and albumin in her urine, which condition had persisted after delivery. The case was treated as one of cystitis by vesical injections, but without much benefit. Some three weeks after the delivery the quantity of urine excreted in twenty-four hours became decidedly lessened, while the amount of pus became both actually and relatively much decreased. At the same time the temperature rose to 104° , and there was considerable pain over the region of the right kidney. An answer to the following questions was desirable: First. Was the *right kidney* chiefly affected, or was the pain on the right side referable to a morbid condition of the left kidney, a possibility to which attention has been called especially by Knowsley Thornton. Second. Were both kidneys diseased or was one healthy? Third. Did the pus really come from the kidneys or was it confined to the bladder? Dr. Hirst was able to solve these problems by the use of the ureteral catheters, which Dr. Kelly was kind enough to lend him. The ureters were made out without difficulty by abdominal palpation, and the catheters, first the metal and then the flexible, were introduced with ease. The specimens of urine collected in separate test-tubes from each kidney showed on inspection a much greater turbidity in that from the right than in that from the left kidney. A microscopic examination revealed pus in both specimens, but in that from the right side in much larger amounts than in the specimen from the left kidney. In the urine from the left side a well-defined granular cast was found. Therefore,

First. The pus came from the kidney.

Second. Both kidneys are diseased; but the right is most markedly affected.

Third. That there is not only pyelitis, but pyelo-nephritis, in the left kidney.

Arriving thus at a precision in diagnosis that would be impossible without the aid of the utereral catheters.

DR. HAMILL had, since the last meeting, palpated the ureters without difficulty, and had passed the catheter into them. The ureters were about the size of the little finger.

DR. KELLY has, since the last meeting, operated successfully for the relief of a ureteritis in an unmarried young woman. The pelvic organs were healthy. The inflammation was confined to the orifices of the ureters. He experienced no difficulty in passing the catheters.

DR. PHILIP M. SCHIEDT read a paper on the

Delivery of the After-Coming Head.

"Time is the great factor in these cases. It is generally conceded that, if the head is not delivered in from five to eight minutes after the delivery of the body, the child will be stillborn." Dr. Schiedt took up the history of the literature of the subject from the time of Celsus and the method of "expression" by suprapubic pressure down through the various manual methods. He deprecated the neglect of this subject by American and English authors, and entered very fully into a criticism of the methods advocated by German and French writers. His own deduction, from an analysis and comparison of these authorities, who widely differ in their teachings, and from his own experience, is that the forceps constitute "the best, quickest and safest treatment." The paper will be published entire in the *American Journal of Obstetrics*.

DR. WM. GOODELL had been struck by what seemed to him a great although common mistake: trying to secure flexion of the head in breech deliveries. In a flattened pelvis, it is better for the head to descend in a transverse position, so as to enable its shortest diameter, the bi-temporal, to correspond to the short diameter of the pelvis, the antero-posterior. In a justo-minor pelvis, the operator would be justified in trying to secure flexion. The fingers in the foetal mouth are useless for good; but there is danger of breaking the jaw. The forceps are the only proper aid in the expulsion of the after-coming head. One objection often made to their use is the loss of time involved in their application; but this does not hold. The accoucheur should be acquainted with the form of the patient's pelvis. The body of the child should be held away, so that the forceps can be applied to the sides of the head, the handles being on the anterior

aspect of the child's body. Another point to bear in mind in a flattened pelvis is the problem of bringing the head safely around the promontory of the sacrum. The hand should grasp the neck of the child, the thumb being on one side and the fingers on the other, and traction should be made so as to ease the head around the promontory before securing rotation of the face into the hollow of the sacrum. After this, it would be easy to make the chin engage or to apply the forceps.

DR. CLEEMAN has never met with any difficulty in delivering the face in head-last labors.

DR. M. PRICE makes it a rule to have his forceps ready in breech deliveries. He has the body held out of the way, and has had no trouble in putting on the forceps. He has had but one death in a breech presentation. On that occasion he had not his forceps with him.

DR. W. S. STEWART prefers breech to head presentations. He has not had trouble in applying the forceps.

DR. LONGAKER laid great stress upon the necessity of avoiding mismanagement in the early stages of a breech delivery; there should be no immediate haste. If the legs are seized and drawn upon, the body is quickly delivered without securing dilatation of the os uteri, and the arms become extended beside the head in the grasp of the lower segment of the uterus. Forcible extraction at this stage is a frequent cause of extensive laceration, and has caused death of the mother. He agrees with Dr. Goodell as to the treatment of these cases in flattened pelves.

The late Dr. A. W. Smith laid great stress on the propriety of using the forceps to assist in the delivery of the after-coming head. In applying the forceps, flex the body of the child toward the dorsum, and the handles of the forceps should be in its anterior aspect. Pressure over the head of the child, while the body is swept toward the belly of the mother, is not a good or safe method; the amount of traction required to extract the head is too great for the neck to bear. The forceps should be in readiness to apply as soon as the body has escaped from the vulva.

DR. ELWOOD WILSON thought it a common mistake to hurry the delivery of the body of the child. When dilatation of the os is complete the child will descend with the arms folded on the body. He is as strong an advocate of the application of the forceps to the after-coming head as any man can possibly be.

DR. J. C. MORRIS could understand the

defense for making traction on the lower jaw by putting one finger in the child's mouth. When the buttocks are emerging, very slight traction will cause extension of the head, but if a hand is passed along the anterior aspect of the child's body and one finger introduced into its mouth, the extension of the head might be prevented. He did not think this defense a good one, as traction on the lower jaw could not be effective. He would quite as soon have a breech as a vertex presentation. The forceps should always be at hand, and there is no difficulty in putting them on. There is need of quick action. Traction on the neck of the child may be productive of great injury. He has known it to result in death, and in loss of power in the lower extremities.

DR. LONGAKER exhibited the ether-inhaler and can combined devised by Dr. Young, of Bridgeport, Conn. He had found it very useful in using chloroform in labor.

DR. BALDY took exception to Dr. Longaker's statements, that fresh air passed through the instrument at every inhalation, and that the patient received a saturated ether vapor, as he considered them conflicting. He preferred the folded, cone-shaped towel.

Exploratory Incision.

DR. MONTGOMERY reported the following case, seen with Dr. E. R. Stone:

Mary G., aged 28 years, married, but not living with her husband. She had noticed for some two months a swelling of the abdomen; this became so marked that Dr. Stone had twice during this time emptied the abdomen by means of a trocar. The fluid was plainly ascitic. When Dr. Montgomery was called the abdomen was again quite well distended; the resonance was that of ascites. Vaginal examination disclosed a mass, quite resistant, situated upon either side of the uterus. The rapidly recurring ascites, with the solid mass in the pelvis, aroused the suspicion of a malignant condition. An exploratory incision was advised, and was made at the Medico-Chirurgical Hospital, October 1st, 1887, Drs. Drysdale, Warder and Stewart assisting. Upon opening the abdomen, two gallons of ascitic fluid were removed and the tumor presented itself. It was covered with papillary growths, which extended also over the posterior surface of the uterus, into Douglas's pouch and over the whole of the left side, so that removal was out of the question. The abdomen was thoroughly sponged out, and the wound closed and bandaged. The following day, frequently repeated doses of salines were

given to produce watery evacuation and drain the peritoneum. She was allowed but little liquid. There was slight elevation of temperature, reaching 100° on the second day. The wound had healed completely at the end of the week. She left the hospital in two weeks, much improved in appearance, and without any appearance of return of the ascites. Since her return home there has been a reaccumulation. Microscopical examination showed the growth to be an ovarian papilloma.

DR. MONTGOMERY exhibited an

Intra-Uterine Fibroid

as large as an orange. It had been removed from a single lady, aged 45 years. She had been suffering from hemorrhage for over three years, but had never been subjected to an examination. A fibroid tumor was found projecting into the uterine cavity from the posterior wall. She was admitted to his private hospital on June 22, and after dilating the canal by a large laminaria tent, on the following day the uterus was secured by a ligature through the anterior lip. The tumor was enucleated as far as the finger would reach, and, finding that the mass was quite large, the cervix was split to the lateral fornix of the vagina on each side, and the enucleation completed by the serrated curette. A drainage tube was inserted, and the cervix closed by three sutures upon each side. The tube was removed on the third day. There was no rise of temperature until the seventh day, when it rose to 103° F., and some cellulitis was found upon the left side. This soon subsided under treatment, but the patient regained her health very slowly. She is now well.

DR. MONTGOMERY also presented a specimen of

Hemato-Salpinx,

removed from a woman twenty-six years old, who had been married twice, and had two children by her first husband. The wound was healed when the dressing was changed at the end of one week. The sac, when opened, contained a firm clot of blood, and from its appearance and history he believed that an extra-uterine or tubal pregnancy had ruptured, causing the hematocele.

—Dr. Unna says that he has seen good results in five cases of leprosy from the external use of the following ointment:

R	Chrysarobin,		
	Ichthyol.....	ãã parts	5
	Salicylic acid.....	"	2
	Vaseline.....	"	100

THE CLINICAL SOCIETY OF MARYLAND.

Stated Meeting, held October 21, 1887.

The 197th meeting of the Clinical Society was called to order by the President, DR. N. G. KEIRLE, in the chair.

DR. J. W. CHAMBERS then showed a specimen of

Cystic Sarcoma of the Inferior Maxilla,

and the patient from whom it was taken. The patient was colored, a male, forty-two years old, a laborer, and of good family history. He entered the City Hospital on September 12, with an enlargement on the right lower jaw, which extended from the last incisor tooth to the right condyle, and involved nearly all that side of the face. It extended inwards and displaced the tongue so as to decidedly interfere with mastication. The growth was cystic in character. It began sixteen years ago after the removal of a tooth, and at first grew slowly; two years ago, it began to grow more rapidly. There was no involvement of the skin, nor of the neighboring glands. On September 16, an incision was made, and the tumor dissected out for the most part with Paquelin's cautery. There was not much hemorrhage. The inferior maxilla was then sawed off and disarticulated. The wound was dressed with bichloride and iodoform. On the sixth day the stitches were removed. There was no shock, and the temperature never rose above 99°. His speech is now much better. Since the operation the patient has developed some mental derangement, but the results show what can sometimes be accomplished even when the conditions presented are apparently hopeless.

In the discussion which followed, DR. O. J. COSKERY thought that Dr. Chambers should be congratulated on the good results obtained in this case. He then showed a specimen and related the history of a case of keloid of unusual size. The patient was a colored man, twenty-five years old. The tumor extended from the lobe of the ear to the clavicle. In 1884, while being shaved, a bump was cut and a sore resulted from it. He applied nitric acid to it which cooled it, he said, but afterwards the pimple grew rapidly. On October 18, 1887, Dr. Coskery removed the growth. An incision about six inches long was made from the lobe of the ear to the clavicle. When the tumor was removed, it left a gap two inches wide. The edges were then brought together. There still remains a gap about five inches long and one-half inch

wide. The patient never had a temperature above 99°. Bichloride dressing was used. He exhibited the tumor on account of its size, as it was the largest keloid he had ever seen.

DR. WM. RICKERT related a case of

Osteoma of the Inferior Maxilla,

and exhibited both the patient and specimen. The patient was colored, male, and about twenty-one years of age. He had been troubled with his jaw for about four years, and had been under treatment for one year. He came under Dr. Rickert's care about three months ago, and finally became so much affected that he could hardly get the tip end of a lead pencil between his teeth. He was then operated on, and a partial excision of the inferior maxilla on the right side performed.

DR. L. McLANE TIFFANY showed several photographs of

Keloid Growths.

He spoke of the largest one, and said that it weighed forty-two ounces. He thinks all of them are larger than the one shown by Dr. Coskery. He did not recognize the difference between true and false keloid as referred to by Dr. Atkinson. They are more common in the colored race, and especially in the young colored race. He had seen them softer in the older colored people. When seen in the young person, non-interference until later in life, then an operation, will meet with good results. After a patient passes beyond thirty years of age they are not apt to recur. There may be a hypertrophic scar, but no lump. Two of the cases he spoke of gave no history of injury.

DR. HIRAM WOODS has seen several cases of keloid at the Presbyterian Eye and Ear Hospital, only one of which occurred in the white, the rest in negroes. The oldest patient was forty-two years of age, and had dumb-bell lumps on her ears, which had become somewhat soft. Ear authorities say that when we operate we must try and get the wound to heal by first intention. He once operated and did not bring the edges close together, and the growth recurred. The more closely we can get a wound to heal by first intention, the better will be the results.

DR. R. WINSLOW said that as these tumors sometimes develop from a puncture with a point of a pin, he did not see why they would not sometimes recur even if the edges are brought close together.

DR. RICKERT thinks that the softening is more common in the white race, and that,

when they are removed they will not return so commonly as in the negro.

DR. I. E. ATKINSON said that his experience was based entirely upon observations in the colored race. He said that Dr. A. B. Arnold once reported a case where a keloid disappeared under the use of collodion. The keloid he had removed in the white patient did recur.

DR. HIRAM WOODS said that he knew that the keloids did develop from the puncture of a pin point, and he simply wanted to say that if, after operating, we can reduce granulation to the minimum, there will be a better chance to get over the disease.

DR. McLANE TIFFANY said that keloid was one of the rarest of jaw tumors. There are only a few reported. Evidently they are cysts lined with epithelium, very much like an ovarian cyst, but it is not settled yet as to what they are.

DR. J. T. BRANHAM said that he had seen a keloid in an old colored man. It was flat, situated on the breast and ulcerated, which he says is rather common. There is no scar tissue when wounds heal by first intention. The case of Dr. Rickert had changed somewhat since he was under Dr. Winslow's charge. The tumor is most probably the result of an inflammatory process and probably not malignant. The removal of this, he thought, was the best thing to do in order to allow the patient to eat and talk comfortably.

DR. RICKERT said that his only object was to give this comfort, and he believed the operation has done vast good to the patient.

DR. CHAMBERS said that he had spoken very little about the finer probabilities in his case. He classed it as a cystic sarcoma. There was no enlargement of the glands, and the growth was slow. The tumor, when removed, weighed about four or five pounds.

DR. KEIRLE said that these growths are very similar to an ovarian cyst. The larger cyst contained chocolate-colored fluid, and the smaller one another colored fluid. They are lined with epithelium like an ovarian tumor.

—RECOVERY AFTER DISLOCATION OF THE SPINE.—The *Chicago Tribune*, Nov. 22, 1887, says: It is reported from Duluth, Minn., that Dr. Slaughter, a well-known physician of that city, has treated successfully a man 55 years old who fell from a scaffold and dislocated his neck. The spinal cord was not compressed by the dislocation. Dr. Slaughter at first prescribed absolute rest. Thursday he applied an apparatus and reduced the dislocation. There is now every prospect that he man will get well.

HOSPITAL NOTES

BELLEVUE HOSPITAL, NEW YORK.

(Service of Prof. F. S. Dennis.)

For the following reports we are indebted to Dr. Thomas McCann, House-Surgeon.

Gunshot Wound of Cranium.

J. C., 18 years old, a driver, was admitted to the hospital at 11.30 P.M., August 29, 1887. While standing in the street, an hour before, he saw a window raised on the opposite side of the street, an arm thrown up and a blaze; after which he fell to the ground. He says that he was not unconscious at any time, and came to the hospital because he felt "the blood running down." The patient was sent to ward 7 as a dressing case and from there was transferred to ward 13, as a case of fracture of the skull. On admission he was examined as to symptoms, and the following noted: Patient conscious; pupils normal; pulse good. As his condition was excellent, it was not deemed necessary to remove the bandages, as it was supposed to be a case of simple scalp wound. On August 30, 9 A.M., the bandages being cut, the following condition of things was noticed: The scalp, for an area of $2\frac{1}{2}$ inches in diameter, showed a small wound at about $1\frac{1}{2}$ inch posterior to the upper margin of the right ear, and another small opening, the size of a 22-calibre bullet, about $3\frac{1}{2}$ inches further up, and at an angle of about 50° . Passing a probe-pointed bistoury into the upper opening a clear track to the lower one was found, which upon being slit open exposed a depressed fracture of about $\frac{5}{8}$ inch square; the patient was also beginning to complain of a sensation of dizziness. Immediate trephining was advised. The patient having been anesthetized, an incision transverse to the line of the bullet was made, and a Galt's trephine applied. After the extraction of the button of bone, it was found necessary to extract the depressed bone. This being done, the inner table was found to be splintered for an area of about 2 inches all around. The spiculæ and loose pieces being removed, an opening, about $1\frac{3}{4}$ inches long by $\frac{5}{8}$ to $\frac{3}{4}$ inch wide, was left. The dura mater was punctured in the centre of the space and a slight tear was found, probably $\frac{1}{8}$ to $\frac{3}{16}$ inch long, in its lower part, exposing a clot beneath it. A small piece of lead was taken from the lower angle of the bone. Three drainage tubes were then introduced, the scalp wound sutured with cat-gut, and antiseptic dressings applied.

September 3. The patient has been in excellent condition since the operation. The wound was re-dressed and the tubes taken out. September 10. Patient feeling better to-day than for many days. September 15. No rise of temperature; no symptoms. October 8. Discharged cured.

Arthritis of Knee.

J. B., 14 years old, was admitted May 3, 1887. Family history good; the boy, fairly well nourished. He states that when $2\frac{1}{2}$ years old he injured his right knee, and was unable to use it up to his tenth year. He has had two operations done upon it—the nature of which is unknown—and also an application of plaster of Paris; the limb being eventually restored to the normal condition. Three months ago he again injured the same knee in falling down a flight of stone steps, and on attempting to rise found the knee stiff, flexed and immovable; which condition has continued ever since. Upon examination the limb was found flexed at an angle of 60° , and immovable. The knee was not tender on pressure, nor was it swollen; the patella was not movable, and two small scars were found at the side of the knee. The patient having been anesthetized, Dr. Dennis made an incision extending directly across and into the joint. The patella was found firmly united to the lower end of the femur, a distinct abscess was detected in the right condyle of the femur, with a corresponding erosion of the cartilage in the head of the tibia, and the joint was completely disorganized. A thin slice was removed from the head of the tibia; the articular ends of each condyle were sawn off; a single silver wire suture was passed through the head of the tibia and lower end of the femur, to the left of median line; drainage tubes were introduced, and the wound was closed by a continuous suture. Anterior and posterior splints were applied with a suitable dressing, and the limb was placed in a wire gauze frame.

May 19. A plaster spica was applied; temperature continued $101\frac{1}{2}^\circ$. May 20. Temperature, $103\frac{3}{4}^\circ$; pulse, 130. Wound re-dressed, looks well, and drainage perfect. May 21. Temperature, $103\frac{4}{5}^\circ$; pulse irregular. Plaster dressing removed, and wound dressed. May 22. Temperature still above normal. A full dose of castor-oil given. May 28, temperature running along a little above normal. The wound was now dressed every two days, and kept in a wire gauze splint. June 1, wound still looking nicely. June 4, drainage removed, plaster dressing applied,

and patient allowed to get up. June 20, plaster dressing removed, and wound dressed. Only a small line of granulation left. July 20, plaster dressing removed; still some granulations; can pass a probe down between ends of bone.

July 21, patient complained of pain, and upon examination a cellulitis of the anterior surface of the lower third of thigh was found. Lead and opium wash was applied, and a plaster dressing over all. July 22, discharged to return for dressings.

Rupture of the Bladder.

M. C., 29 years old, single, a driver, was admitted April 12, 1887. Thirty-six hours before admission he was knocked down by a cart loaded with coal, which struck him on the right side, one inch below the crest of the ilium. The patient refused to be brought to the hospital until the following day at 5 p. m., when he was admitted with the diagnosis of ruptured bladder. His condition was fair, with little pain; temp., $98\frac{1}{2}^\circ$. He had passed his urine one hour and a half before the accident. A catheter being passed, two ounces of light colored urine were withdrawn. Two previous attempts had effected the same result. With the above exceptions, no water had been passed since the time of the accident. At 9 p. m. the catheter was again passed, and two ounces of urine were withdrawn. A warm solution of Thiersch's fluid was then injected, and it was all returned, with fifty-seven ounces of fluid in addition, bloody and highly colored.

The conclusion arrived at was that there was no rupture, but "probably a laceration of the right kidney, with a bladder atonic from distention." The reasons for this conclusion were: first, the fact that the patient had passed his urine one and a half hours before the injury; second, the wheel not having passed entirely over the abdomen, but merely pushed the patient forward on the ground; third, the absence of any sign of shock, peritonitis, etc.; fourth, fluids injected returning almost in toto; and fifth, slight tenderness over the region of the bladder was present, it is true, yet there was an entire absence of any grave symptoms warranting the diagnosis of a ruptured bladder. Laparotomy being deemed inadvisable, sedatives were ordered, and use of the catheter every three hours.

April 13. Bladder again washed out with six ounces of Thiersch's solution, and twenty-five ounces of fluid were withdrawn, thus strengthening the theory of atony of the

bladder. The patient was now comfortable, and had no pain nor fever.

April 14. Passed thirty-four ounces of urine. Toxic symptoms, probably uræmic, now appeared.

April 15. Toxic symptoms partially disappeared. Patient passed sixteen ounces of urine, and then began to vomit. Castor oil was ordered on the 14th, the patient having had no passage since the accident; but it failed to cause an evacuation, and an enema was ordered. This was followed by slight movements.

April 16. The same condition as on the 15th. Patient vomits, and is not able to as-

similate food. Bowels confined; slight pains still present; no rise in temperature; passed fourteen ounces of urine. Hiccough now set in.

April 17. Patient sat up, reading a paper, and expressed a desire to go home. At noon he suddenly became comatose, and died fifteen minutes after the first indication of danger. The autopsy revealed a rupture in the posterior wall of the bladder two inches in length; the intestines, being matted together by a thick coating of fibrin, forming in a certain degree a sac for the retention of the urine. There were distinct evidences of septic peritonitis.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Frequency of Sterility in the Male.

The following *résumé* of F. A. Kehrer's investigations is given by A. Martin, in the *Centralblatt f. d. med. Wissensch.*, September 10, 1887:

The cause of childlessness in many marriages is to be sought much oftener on the side of the man than has heretofore been the custom. This statement is based upon an investigation of the semen. Kehrer has up to the present time instituted this investigation in ninety-six cases. In 3.12 per cent. there existed inability to copulate; in such cases there had always been preceding masturbation. The men suffered from frequent pollutions, or the ejaculations were premature, so that the penis was not inserted into the vagina. In these cases impregnation may result, if before the attempt at coitus a speculum be introduced into the vagina. In several cases conception was obtained by this manoeuvre. In 31.21 per cent. azoöspemia existed. In most of these cases gonorrhœa with unilateral or bilateral orchitis had preceded. The author lays particular stress upon occlusion of the ejaculatory duct through gonorrhœal prostatitis. But azoöspemia was also found where no disease of the sexual organs had occurred, and where nothing abnormal in the genital organs could be demonstrated. Oligospermia was demonstrated in 11.45 per cent. Several times masturbation was confessed, or else gonorrhœa with orchitis, or syphilis, had preceded.

But, in addition, the author thinks that the disease of the female sexual apparatus,

which may condition sterility, are considered too numerous. Principally, catarrhs under certain circumstances lead to sterility, and Kehrer also thinks that bacteria may exert a destructive influence upon the ovules. It is a question whether these bacteria produce inflammation of the mucous membrane, or only find in the latter suitable conditions for further development.

The Connection Between Injuries of the Head and Inflammation of the Lungs.

Roche has recently treated this subject critically and analytically, and has been led to adopt the following classification of the lung affections mentioned:

1. Those accidentally present with the head injury.

2. Those which occur solely in consequence of the cranial injury.

To the first group belong the so-called fibrinous contusion pneumonia, the hypostatic pneumonia, which sometimes follows other injuries in consequence of imperfect distension of the lung, and metastatic pneumonia, caused by emboli from infected wounds of the head.

To the second group belong deglutition pneumonia and that caused by the inspiration of foreign bodies, which occur especially in consequence of simultaneous paralysis of the cortex and the vagus centre, or by the first simply through unconsciousness.

Roche states his conclusions axiomatically as follows:

1. Proof of the casual connection of injury to the head and fibrinous pneumonia cannot be produced.

2. Hypostatic pneumonia, complicating cranial injury, presupposes great prostration

of the person injured. This can have occurred before the injury (old age) or be caused by it.

3. Metastatic pneumonias following injuries of the head always indicate an infection of the wound. They therefore stand in direct connection with the lesions.

4. Deglutition, foreign body, or vagus pneumonias, which develop after cranial lesions, stand in the most direct connection with the latter. They indicate relatively intense application of force, and are to be looked on as the consequences of paralyzing effects on certain cerebral regions.—*Vjhrschr. f. gerichtl. Med.*, N. F. xlvii, 1, p. 12, 1887.

Myotomy in Pregnancy.

In the *Münchener med. Wochenschrift*, No. 52, 1886, Frommel gives as indications when to perform an operation for removal of fibroids of the uterus in pregnancy: 1. Subserous tumors capable of enormous growth. 2. Situation of the myoma in such a way as to make the birth of the child by delivery impossible. 3. In hemorrhage or threatened softening and decay of the tumor. The author has operated on a case in which the tumor occupied the broad base of the wall of the uterus. Convalescence was disturbed by poisoning with iodoform, but pregnancy was not interrupted.

Sour Milk and Buttermilk in the Nutrition of Invalids and Others.

As the result of an extensive experience in rural practice, Dr. Demuth (*Vereinsblatt d. pfälz Aerzte*, iii, p. 85, May, 1887) extols sour and buttermilk as cheap, effective and easily assimilable nutritive agents. Both are easily digested on account of the finely divided condition of the casein and the presence of acids. For infants the following is especially recommended: one quart of buttermilk boiled with one tablespoonful of wheat flour to the consistency of thin pap.

Buttermilk is useful in all cases where a milk-cure is indicated, and is particularly to be recommended in consumption. Sour milk has shown itself valuable in scrofulosis, neurasthenia, hypochondriasis, in convalescence, in diseases of the organs of respiration and deglutition, chronic catarrh of the air passages, nervous disturbances following excessive or exclusive meat diet, dropsy, albuminuria, and Bright's disease. It is also useful in diabetes mellitus. Both forms of milk are efficacious in chronic metallic poisoning, and inflammatory and febrile condi-

tions, especially in typhoid fever. They are contra-indicated in all ulcerous processes in the alimentary tract,—a fact not always considered in ulcer of the stomach, ulcerating cancer, and tuberculous ulceration of the intestines,—and in dilated stomach.

Recto-Vaginal Fistula.

In the 48th section of the *Deutsche Chirurgie*, Esmarch publishes a very complete study of diseases of the rectum and anus. In this work he advises, in the treatment of congenital recto-vaginal fistula, that the surgeon shall not content himself with opening the perineum, and freshening and closing the edges of the opening into the vagina, but that he shall free the rectum completely from the vagina, and draw it down separately and attach its circumference to the skin. This method, he believes, will give better results than the simple one referred to above.

Rheumatic Nodes.

At the Congress of the German Naturalists and Surgeons, in September, 1887, Krukenberg (*Gazette Médicale de Paris*, November 5, 1887) presented the case of a patient in whom the diagnosis of osteo-sarcoma of the thigh had been made, and who expected to have his thigh amputated. For about six years this man had suffered from muscular rheumatism, and for a month had experienced lancinating pains in the thigh, with diffuse swelling and redness in the anterior part of this region. Touch revealed a focus of induration, which occupied in an irregular way the adductors and extensors of the thigh, and penetrated deeply into the tissues. Trendelenberg diagnosed a rheumatic node. The muscles did not respond to electric stimulation. The patient was put to bed, and recovered under systematic massage and Faradization of the muscles.

With reference to the differential diagnosis between rheumatic nodes and malignant tumors, Krukenberg calls attention to the special modifications of the skin which occur in nodes, the contracture of muscles, the loss of electric excitability of the same, and finally the relatively good state of nutrition.

Mechanical Treatment of Painful Erections.

The nocturnal erections of patients suffering from gonorrhœa are due (1) to the inflammatory irritation to which the penis is exposed; (2) to lying upon the back, and a distended bladder; (3) to the loss of the inhibitory influence of the brain. The pain

which accompanies them is caused by the fact that the inflamed condition of the mucous membrane of the urethra does not permit it to follow the expansion of the corpora cavernosa, but is stretched frequently to such a degree that the small vessels of the mucous membrane are lacerated. M. Anthelme Jamin, resident physician of the Lyon's Hospital, having noticed that patients with gonorrhoea hold the penis down upon the scrotum by flexing one thigh upon the other, and so prevent erections, was led to make a suitable T bandage to accomplish the same purpose. In a communication on the subject to the *Lyon Medical*, he reports successful results in twelve cases in which he has used it, and thinks that other painful erections might be prevented in the same way.—*Deutsche Medicinal-Zeitung*, October 6, 1887.

The Pathology of Diseases of the Nervous System after Malaria.

Dr. Singer, of Prague, reports the following case in the *Prager med. Wochenschr.*, 18 u. 19, 1887: A man, twenty-six years old, was taken sick, in Singapore, with malaria. After he had been treated in vain by quinine for eight days, he recovered after a sojourn of fourteen days in the mountains. On his return to Singapore, the patient had sensations of formication and of prickling between his toes, associated with a weakness of the lower extremities, which gradually increased to paresis. After several days the same symptoms appeared also in the upper extremities, but paralysis was not so strongly developed. Then the tongue and face shared in the paresthesias. In addition, bilateral complete facial palsy developed. There was no fever; no objective disturbances of sensibility; the sphincters were not involved, and change of climate effected recovery. An investigation, undertaken by Singer, showed that there were still slight paresis of the right as well as complete paralysis of the left facial, emaciation and weakness of the left upper extremity, slight weakness of the lower extremity in bending the knee joint, loss of the patellar reflexes, some swelling and sensitiveness of the left submaxillary lymph glands, reactions of degeneration in the paralyzed (left) facial nerve, diminution of the electrical excitability for both currents in the right facial. Everything else was normal.

Under systematic electrical treatment, great improvement took place; but, at the time the report was made, the patient had not entirely recovered.

The author thinks from this case, and from one of Buzzard's, that in convalescence from

a severe attack of malarial infection, the peripheral nerves can become affected with acute polyneuritis, which reminds one very much of the post-diphtheritic paralyses. The poly-myelitis of beri beri is excluded in this case.—*Deutsche Medicinal-Zeitung*, October 3, 1887.

Contribution to the Anatomy of the Brains of the Deaf and Dumb.

Dr. Julius Waldschmidt, of Freiburg, in a communication to the *Allg. Zeitschr. f. Psych.*, Bd. 43, h. 4 and 5, 1887, reports upon a microscopic examination of the brains of two deaf mutes, one of which came from a man forty-six years old, and the other from a girl nineteen years old. These showed a stoppage in the development, in respect to form and size, of the island of Reil of the left side, and especially of the parts placed anteriorly, which seemed absolutely rudimentary when compared with corresponding parts on the right side. Waldschmidt thinks that, with all proper reserve, he can draw the conclusion that in deaf and dumbness a degeneration of the *centres* for speech and hearing (the operculum, the third left frontal convolution and the temporal lobes) is not absolutely required, but that an interruption of the conduction is quite sufficient to form the basis for deaf muteness.—*Deutsche Medicinal-Zeitung*, October 17, 1887.

Uterine Disease in the Production of Insanity.

Dr. Alice May Farnham, after a careful study of a number of cases, announces her opinion as follows in the *Alienist and Neurologist*, October, 1887:

In the study of the relation of the mind and the female genitalia, as set forth in this paper, the following conclusions may be drawn:

1. That while the female reproductive organs and the brain are closely associated, often acting and reacting upon each other, uterine disease alone is seldom or never the cause of mental alienation. Other conditions, as hereditary predisposition to insanity, poor bodily health, or mental worries, one or all furnishing the necessary adjunct to the development of disorders of the mind.

2. That, in insane women, irritation of the genitalia often gives a peculiar character to the mental condition. And

3. Menstruation, like any periodic lowering of the standard of the general health, frequently acts, in cases of mania, as the excitant of the most marked maniacal outbursts.

Removal of Cerebral Tumor.

At a meeting of the Medical Society of London, October 31, 1887, Dr. Hughlings Jackson, showed a man, aged 21, a patient of his, who had been subjected to severe, and also slight, epileptiform attacks (beginning in the left thumb) since 1884. Although no positive symptoms of cerebral tumor were present, it was decided to cut down and remove the tumor if one were found, and also part of the motor area for the thumb. Mr. Victor Horsley operated more than a year ago, and finding a tumor in the right cerebral hemisphere, removed it and also part of the thumb-area. The result had been to lessen the attacks both in number and severity; for, whereas before the operation the lad had had as many as fifteen attacks in thirteen days, he had only had eleven attacks since the operation, only one of which was severe enough to lead to loss of consciousness.

Death Under Chloroform.

The *British Med. Journal*, November 5, 1887, reports that a death under the influence of chloroform occurred in the Croydon Infirmary, on October 18. The patient was a man, aged 28, who came under treatment on June 22, for pleurisy with effusion. The chest was aspirated on September 15, and about four pints of serum withdrawn; aspiration was repeated on September 20, when three pints of serum were obtained. On October 17, the chest having again filled, aspiration was performed for the third time, and five and a half pints of pus were evacuated. Following the method of treatment which is now thoroughly established as a rule of surgical practice, Dr. Francis W. Clark, the medical officer in charge of the infirmary, after consultation with Dr. Strong and Dr. Matthey, determined to open the chest wall in order to allow of free drainage. On October 18, chloroform was administered, and the operation was performed in the ordinary manner. During the last steps of the operation symptoms of syncope suddenly developed, and all efforts to restore the patient were unavailing. Every precaution was taken in administering the anæsthetic.

Artificial Fecundation.

Professor Paolo Mantegazza communicates the results of his rich experience in a leading article in the *Gazzetta degli Ospitali*, of Milan, February 6, 1887. He says that the act of artificial fecundation in itself requires no special skill, but that it is important to

be able to determine with certainty whether there is hope of a successful result or not. There is always great repugnance on the part of both husband and wife to the operation, and therefore it is clear that unless there is good hope of success, it should be abandoned. It must first be determined whether the obstruction to conception rests with the husband or wife; and in this connection it is well to recollect that impotence is only rarely confessed. For example, the author once saw by accident that a man who was otherwise robust, but childless, had an extremely short penis. Here, if ever, was a suitable opportunity for artificial fecundation, because his wife had the appearance of blooming health; but the author was not successful in persuading them to it. In another case, the penis was of the proper length and strength, but the semen, on account of stricture or some other cause, was only expelled in drops, so that it with great difficulty reached the uterus. Also, in men with only half or very slight power, the semen only reaches the anterior part of the vagina, and so sterility results. After the man is questioned with the utmost exactness upon the manner in which coition is completed, the semen must be examined microscopically. In this respect Mantegazza thinks he has discovered a new fact. In one case, having several times endeavored to obtain artificial fecundation in the same woman without success, although the semen had a good appearance and proper reaction, and the spermatozoa were numerous and active, he noticed that the crystals, which he first observed in 1860, but which were first described by Böttcher, did not appear when the semen was allowed to stand. He is disposed to think that such absence constitutes an anomaly which deprives the semen of its fructifying power.

With reference to the causes of sterility in the female, he would divide them for the most part into two classes: mechanical and functional; and while not disposed to think the existence of the former class a contra-indication to artificial fecundation, thinks the latter class, which can be placed under the head of dysmenorrhœa, is. He admits that there are many cases of dysmenorrhœa which depend upon mechanical difficulties, which dilatation of the cervix will cause to disappear. As far as sterility is concerned, the worst cases are those in which removal of the dysmenorrhœa by mechanical measures does not result in fertility. In such cases Mantegazza thinks the fault lies with the ovum. Of what use is it, says he, to

introduce semen into the uterus, if it finds there no ovum capable of fructifying? According to the author, artificial fecundation may be indicated in the following cases: 1. Hypospadias. 2. Very short penis. 3. In cases in which the semen is discharged without the necessary force, or in drops. 4. In all cases in which a decided change in position of the uterus, or a very narrow cervical canal hinders fecundation. 5. An unsuccessful treatment of the cervical canal by dilatation forms no contra-indication to artificial fecundation. 6. In all cases in which dysmenorrhœa persists, and yet the cause of the sterility remains unknown.

After stating that he has found that it is generally the man who objects most to the operation, on account of the rather humiliating rôle which he is required to play, the author says that during the eight days following menstruation is the best time for the operation, which, if unsuccessful then, may be tried the day before menstruation. The method of obtaining the semen, which Mantegazza has found the best and most seemly, is the following: The husband has connection with his wife, but instead of emptying the semen into the vagina, he deposits it in a glass, which stands in water at a temperature of from 98° F. to 103° F., and then calls the physician. The latter then introduces a Fergusson speculum and makes two or three injections with Roubaud's syringe. The patient may then be advised to stay in bed several days, with the pelvis raised, though this does not seem necessary.

The author has never seen untoward results from making three injections, and thinks the fear expressed by other writers unfounded. After coitus, the mouth of the uterus was generally found not completely closed; if the act was entirely natural ("without Malthusian retraction") semen was always found in the posterior vaginal *cul-de-sac*; it is possible then to cause the semen to flow into the mouth of the uterus by means of the speculum, especially if retroflexion exists. In case the wife should positively refuse to let the physician interfere, Mantegazza would then propose that the husband attempt artificial fecundation in this way, though he warns against allowing the husband to use Roubaud's syringe.—*Deutsche Medizinische Zeitung*, October 17, 1887.

Vesico-Vaginal Fistula.

At the Congress of German Naturalists and Physicians, in September, 1887, Dr. Rose, of Zürich, reported that, in a young woman, whom another physician had been unsuc-

cessful in relieving of a vesico-vaginal fistula, he had obtained a successful result by closing up the vulva, and making a recto-vaginal fistula. He remarks, in this connection, that success in the operation demands that the opening between the rectum and vagina should be kept open by daily dilatation, which is best accomplished with the finger.—*Gazette Médicale*, November 5, 1887.

Aneurism of the Aorta Cured by Operation.

Lépine describes, in the *Province Médical*, 1887, No. 22, a case of aneurism of the aorta cured by insertion of a watch-spring. He did not follow the usual plan of introducing the watch-spring through a canula; but had the end sharpened to a lancet point, and passed it directly into the aneurismal sac. Lépine recommends this plan for the treatment of sacculated aneurism of the anterior side of the ascending aorta.—*Centralblatt für Chirurgie*, October 8, 1887.

Innominate Aneurism—Ligation of Common Carotid—Temporary Recovery.

Dr. G. B. Ferguson describes, in *St. Bartholomew's Hospital Report* for 1886, the case of a man, 43 years old, suffering with an aneurism the size of a walnut, near the roots of the right carotid and subclavian arteries, who was apparently cured by ligation of the common carotid artery, and lived in comparative comfort for a year afterward. At the end of this time he died, and it was found *post mortem* that he had an aneurism of the posterior wall of the ascending aorta, as large as a fist, and continuous with the cavity of the aneurism of the innominate artery, which was empty of clots. His conclusions are: 1. That the innominate aneurism was practically cured by the operation. 2. That simultaneous ligation of the subclavian would not have assisted matters. 3. That the aortic disease was incipient from the first, and was uninfluenced by the treatment. 4. That the chromicized catgut ligature, tightly tied, is a satisfactory and trustworthy material in such cases.

Chorea Cured by Typhoid Fever.

Dr. Samuel West records, in *St. Bartholomew's Hospital Report* for 1886, the case of a girl, 10 years old, who was attacked with typhoid fever three weeks after her admission to the hospital for chorea of a moderately severe type. As soon as the typhoid fever developed, the chorea stopped, and it did not return. The fever was well marked, but mild, and lasted three weeks.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
 CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.25
Reporter and Pocket Record, - - -	6.00
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets,
 P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 10,250 copies.

LEPROSY IN AMERICA.

The recent discovery by the public that for some time past two persons suffering with leprosy have been living, unsuspected, in this city, has attracted a great deal of attention to the subject of leprosy, and excited considerable alarm. Some of the Health Officers of the city, seeming to share the popular fear, made an attempt to secure and isolate the persons of the sufferers. At first this attempt did not succeed, because the physician who had them under his care, and who had kindly exhibited them at a meeting of the County Medical Society, refused to disclose their whereabouts. In doing this we suppose he was influenced by a creditable spirit of professional honor, founded upon the belief that these two unfortunates were not dangerous to the community. If this surmise is correct, we can heartily approve of Dr. Van Harlingen's course, for our confidence in his judgment is as great as our appreciation of his skill as a dermatologist.

After a short delay, however, the two persons alluded to voluntarily gave themselves up to the health authorities, and were taken to the Municipal Hospital for contagious diseases. Here they were treated with an extreme of caution which showed the exaggerated notion there prevailing in regard to the contagiousness of leprosy.

In view of these facts, it is important to discuss the contagiousness of this disease; for if it be very contagious, scarcely any measure could be regarded as too severe which would protect the community from its ravages. As a matter of fact, we do not hesitate to say that there is little evidence to show that leprosy is contagious—in the usual sense of this term—anywhere; and none to show that it is so in this country. From various parts of the world cases have been reported in which the communication of leprosy by contagion seemed to have taken place. But these are very rare cases among the many in which leprosy occurs, and it is quite possible that in considering them an association of events has been erroneously taken as evidence of a causal relation.

In the United States, and British possessions in North America, lepers have been found in small numbers at almost all times; but we think no case of contagion has ever been reported. In Nova Scotia and in Louisiana there are small colonies of lepers, and a certain number have come to our Eastern and Western ports from across the seas; but there is no evidence that either the colonies or the individual lepers have propagated the disease. In England a similar experience has prevailed.

Curiously enough, at this very time there is an excitement in England, as here, in regard to the danger to the community from a few persons suffering with leprosy, whose presence has been revealed to the public.

The matter has attracted the attention of the Royal College of Physicians, which some years ago appointed a committee to prepare an authoritative statement in regard to it. This committee reported that leprosy, though a terrible disease, is not much worse than others which are not held to justify

compulsory segregation of the patient, and that lepers ought to be treated as persons suffering from a severe and occasionally contagious malady, not as monsters accursed by God and man.

We cannot spare space here for a presentation of the reasons which influenced this committee, or which influence us to raise a voice against the clamor of fear which has risen about leprosy. But we feel assured that others who will study the subject carefully will conclude that nothing is to be feared, in England or in North America, from the presence of a few lepers. They are to be treated as other sick folk, with kindness and the best skill available, keeping in view the remote possibility that the disease may spread from them. But, until a single authentic instance of its communication by contagion in this country can be adduced, it is the height of folly to demand their separation from their fellows, to treat them as if they had small-pox or scarlet fever, and to excite the laity to an unreasonable fear and horror of them. Physicians, who entertain other opinions in regard to the contagiousness of leprosy, may effect all that is necessary for the protection of the public without exaggeration of its danger. At present the need seems to be that exaggerations which have been set in motion should be checked, and the confidence of the people in the ordinary methods of medical and sanitary protection should be re-established.

STRYCHNIA AS A HEART STIMULANT.

In *St. Bartholomew's Hospital Reports*, vol. xxii, there is a valuable paper by S. HERBERT HABERSHON, M.B., on the use of strychnia by hypodermic injections in cases of heart failure. In this paper Dr. Habershon discusses the *modus operandi* and effects of various heart tonics, such as digitalis, alcohol, ether, and ammonia, and concludes that none of them are so useful as strychnia in cases in which not only the heart muscle, but also the nerves which promote and control its activity are exhausted. The order of excellence seems to be digitalis for a pro-

longed effect; and ammonia, or ether and alcohol, for a more rapid but less lasting one.

It is somewhat surprising to find the statement that Dr. Habershon has never found ammonia "to act where brandy and ether have not succeeded." This sentence is not easy to analyze, but we incline to the opinion that if ammonia be used by intravenous injection, it will be found capable of arousing the vasomotor and respiratory centers to a temporary activity when nothing else will.

The principal value of Dr. Habershon's paper is in calling attention to the influence on the heart by hypodermic injections of from $\frac{1}{80}$ to $\frac{1}{30}$ of a grain of strychnia. He cites cases of disease of the mitral and aortic valve, and of pneumonia which had advanced to a state of cyanosis, with weak and rapid pulse, and hurried or Cheyne-Stokes respiration, in which the use of strychnia seemed to cause the tide of life to turn back, and recovery ultimately took place.

These cases may be regarded as establishing the opinion which he has formed of the great benefit to be derived from the hypodermic use of this drug in conditions of exhausted heart-muscle, accompanied by exhaustion of the nerves which supply the heart. Dr. Habershon suggests that the most convenient solution of strychnia for hypodermic use consists of one grain in fifty minims of water. We would suggest that it would probably be easier to regulate the dose if the solution were only about half as strong as this, consisting of one grain of strychnia to one hundred and twenty minims (two fluid drachms) of water. Two minims of such a solution would contain $\frac{1}{60}$ of a grain of strychnia, and four minims $\frac{1}{30}$ of a grain.

We recommend the views just stated to our readers, and hope that their adoption may prove satisfactory to them and advantageous to their patients.

VEGETARIANISM.

The *Chicago Tribune*, November 16, 1887, contains an amusing sketch by F. H. Carruth, in which he makes great fun of the habit of eating macaroni, Graham bread, oat meal, etc. The humor of this article is not very

delicate, and its scientific value is *nil*. The fact is, that a diet from which animal flesh is excluded is not only sufficient for all the needs of mankind, but sufficient to develop the most robust bodies and support the most vigorous minds. There are no finer set of men to be found anywhere than the Brahmins of India, who never eat meat in any shape; who are so scrupulous that some of them strain the water which they drink, so as to exclude from it any minute creature which it might contain. In body and in mind they are among the finest specimens of mankind. And in civilized countries, there are many men of clear complexions, sturdy frames and keen intelligence, who never eat meat.

We do not think the moderate use of meats prejudicial to health; but no more do we doubt that the use of meat is responsible for a great deal of the digestive disorders of our fellow-men. One result of imperfect digestion, which afflicts many civilized and refined people, is an offensive breath, which is probably due, in the majority of cases, to decomposing animal tissue contained in the alimentary canal. Let those who reflect on this matter compare in their minds the sweet breath of the herbivorous and granivorous animals with the foul breath so often emanating from the carnivora.

If mankind will imitate the conduct and choose the food of the most savage and most cowardly part of the animal kingdom, let them not deceive themselves into believing that their physical needs compel them to do so. Much less let them make pseudo-scientific jokes about it. They may eat meat and they may get good nourishment out of it; but if they wish to confine themselves to the diet indicated by nature, and to take no life in order to please their palates, they need not fear physical, mental or moral decrepitude.

A DANGER FROM SEWING-MACHINES.

Most medical men are sufficiently impressed with the fact that constant use of the sewing machine exercises an injurious influence upon the sexual organs of women,

having a tendency to inaugurate or increase disorders of menstruation, leucorrhœa, and other inflammatory conditions of the uterus. But Dr. GEORGE T. WELCH reports, in the *Transactions of the Medical Society of New Jersey*, for 1887, the cases of two women, one married and one unmarried, in whom constant use of the sewing-machine produced erythism, and an actual orgasm. In both women this result led to undermining of the general health and spirits.

Such cases, we trust, are rare; and yet it may be well for medical men, and especially for medical women, to know that they may occur, and to be on the look-out to detect and remedy them. If they were very frequent, the sewing-machine ought to be banished from the house and the factory. It might be worth while for some discreet woman physician to investigate this subject, if the investigation could be carried out without offering a suggestion to women-workers which could increase their danger.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

We regret to notice that the *Journal of the American Medical Association* has not the courage to refuse to publish what are known as "reading notices," or puffs in the reading pages of wares advertised in the proper advertising pages. It certainly would seem reasonable to expect that a magazine supported by a species of forced contributions from the members of the Association would hold to a strict observance of high principles in medical journalism. Six months ago, the *Pittsburgh Medical Review* called attention to this matter, and it is painful to find that the editor-in-chief of the *Journal* of the Association cannot prevent what we feel sure he must deplore.

—Stadelmann, of Heidelberg, regards diabetic coma as a poisoning by acid, and again recommends intravenous injections of a three per cent. solution of carbonate of sodium in a half per cent. solution of chloride of sodium.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

SEVENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF NEW YORK. Transmitted to the Legislature, January 19, 1887. 8vo, pp. 639. Albany: The Argus Company, Printers, 1887.

This volume of reports contains much that is interesting and valuable to students of public hygiene, especially in regard to water supplies, ice supplies, food adulteration, drainage and sewerage. One of the most curious chapters of this Report concerns the objections raised by the Water Company of Jamestown to an investigation as to the purity of the water supply of this town by the State Board of Health. The objections show to what lengths of evasion a mercantile interest will go in endeavoring to escape doing its duty; and we are glad to say they are thoroughly overthrown by Dr. Lewis Balch, Secretary and Executive Officer of the Board.

A SHORT MANUAL OF SURGICAL OPERATIONS. By ARTHUR E. T. BARKER, F.R.C.S., Surgeon to University College Hospital, etc. With 61 illustrations. 8vo, pp. 423. London and New York: Longmans, Green & Company, 1887. From J. B. Lippincott Company. Price, \$3.25.

In his preface, the author speaks of this book as "a small work," and altogether indicates a modest opinion of its scope. In this, he does himself credit. But we have no reason to measure our words in appreciating it, and do not hesitate to say that it is a work of great importance and of great value. It is admirably planned and admirably executed. It presents, in clear and attractive style, the best methods for performing almost all the surgical operations now in general use, and some which are still rare. The illustrations, drawn by the author, are beautiful and distinct, and enhance the value of the text very materially. The work of the publisher is also well done, paper, printing and binding being excellent. Most readers, we think, would prefer books, the pages of which have been cut; but those who like to use the paper-knife will have an opportunity here.

In considering the contents of this manual in detail, we find little to criticise, and this little we would comment on with due deference to the author's experience. The treatment of varicose veins of the leg by excision, we think, might be described with greater fulness without disadvantage; the use of Malgaigne's-hooks for fracture of the patella might be mentioned, even if the author—like the reviewer—does not approve of them. We miss a description of the Wladimirow-Mikulicz operation for resection of the tarsus. The chapter on excision of the tongue is so admirable that we wish it had been perfected by a more detailed account of the steps of Kocher's method. In the chapter on operations upon the ovaries, we think the methods of Sir Spencer Wells are followed too closely; and we cannot approve of the use of the spray. In the description of suprapubic lithotomy, we note an array of instruments, some of which are not needed, and one of which, the *sonde-à-dard*, is both useless and obsolete.

These are some of the points to which we would call the attention of the author. To our readers, we

would say that we know no work on purely operative surgery which is better suited to the needs of surgeons, who would be well instructed. The points in it, in regard to which we have commented above, are few compared to those which have excited our hearty approval.

TRANSACTIONS OF THE MEDICAL SOCIETY OF NEW JERSEY, 1887. 8vo, pp. 412. Newark, N. J.: L. J. Hardham, Printers, 1887.

This is a volume which reflects great credit upon the publication committee of the New Jersey State Medical Society, whose work of editing is very well done, and upon the printer who issued the book. The transactions of the Society are interesting, although they comprise only three original medical papers, one of them being a prize-essay on "The Climatology and Diseases of Essex County," which covers 160 pages. The other two are by Dr. B. A. Watson and by Dr. D. Benjamin. All of them are interesting and instructive. The prize-essay is a model of thoroughness.

The reports of District Societies cover 103 pages, and contain a number of excellent brief papers—one of them in rhyme—which deserve the wider reading which the columns of a medical journal would afford.

HYGIENE FOR YOUNG PEOPLE. PATH-FINDER PHYSIOLOGY NO. 2. 5¼ x 7½ inches, pp. 207. New York and Chicago: A. S. Barnes & Company. Price, 60 cents.

This book is very similar to one reviewed in our last issue, and is designed for older children. It has the same merits as that has, and is subject to the same qualifications. As an illustration, we would cite the exaggerated use made of the fact that alcohol combines with water, taken in connection with Dr. B. W. Richardson's estimate of the water which had dried out of a mummy. The use of this story in connection with the statement made about alcohol, we do not regard as fair; and the inferences which a child would draw from it would probably be very erroneous. We may be wrong; but we believe the proper way to inculcate temperance is by showing its advantages and the evils of intemperance; and that more should be made of the importance of self-governance. Children should be taught to rule their conduct, to restrain their appetites, to choose what is good for its own sake; and that to yield to wrong is not only sinful, but unmanly and unwomanly. We believe that it would be both right and useful to cultivate the idea that the man or woman who is intemperate in anything: passionate, extravagant, a drunkard, or lustful, is *quoad hoc* to be despised, while true temperance and the pursuit of good are the noblest achievements of which man is capable.

A HAND-BOOK ON DISEASES OF THE SKIN. By ROBERT LIVEING, A.M., M.D., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, etc. Fifth edition, revised and enlarged. Small 8vo, pp. viii, 451. London and New York: Longmans, Green & Company, 1887. Price, \$1.50.

The fifth edition of Dr. Liveing's manual on skin-diseases contains an admirable presentation of the subject, as may be imagined from the fact that it is the fifth edition. It is written in a clear and succinct style, and its teaching in regard both to the pathology and treatment of the skin-diseases is trustworthy. The discussion of the pathology of skin-diseases is fuller and better than that of this treatment—a part of the book which was not embraced in the first edition,

and which does not seem to have caught up to the development of its older brother.

We find that the author is opposed to the use of ointments in acute eczema; and dwells upon the importance of rest, general and local. In the main, these injunctions agree with the experience of other dermatologists; but we do not think they are to be taken as exclusively as the author's language seems to indicate. We have looked in vain for any reference to dermatitis herpetiformis, as recently described by Duhring. In regard to leprosy, to which so much attention has been attracted of late in England and the United States, we find the author believes it to be contagious; although he admits that there are no well authenticated cases on record of its communication by contagion in temperate climates.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—G. P. Putnam Sons announce that, after January 1, the *Medical Analectic* is to be issued in weekly numbers. This journal is made up entirely of selections and abstracts from American and foreign journals, and is conducted with marked ability.

NEW INSTRUMENTS.

WILCOX'S DIGITAL FORCEPS. SOLD BY S. R. WILCOX, BENNINGTON, VT. Price, \$2.50.

The accompanying cut illustrates very clearly the appearance and manner of using an instrument which has been sent us by the inventor for notice. The design consists in attaching a species of blunt curette

to the index, in such a way that the instrument can be used as a curette, or in combination with the finger as a fenestrated forceps. The advantage, in many cases, of such a combined digital and instrumental manipulation must be obvious. The instrument was originally intended for use in cases of adherent placenta; but there are several other conditions of the uterus in which it might afford valuable assistance.

CORRESPONDENCE.

Asthma Cured by Relief of Constipation.

EDS. MED. AND SURG. REPORTER :

Sirs :—I have recently had a patient of German parentage, 63 years old, weighing 230 pounds, with a dark complexion, and a temperament in which the lymphatic and bilious tendencies decidedly predominate over the sanguine and nervous. Has been troubled with obstinate constipation as long as she can remember, notwithstanding the fact that she indulges freely in the use of beer. The interval between evacuations varied from six to ten days, and a motion of the bowels was secured only by the use of powerful cathartics. For years the woman had suffered extremely with asthma, from which she secured only temporary relief by the use of inhalants, antispasmodics and nervines.

On February 9, 1887, she was taken ill with a high fever and diarrhoea, and soon had a fully developed enteritis. She recovered from this under appropriate treatment; but, being anxious to be about, she got up too early, and relapsed into a condition of general peritonitis, which, under appropriate treatment, subsided and convalescence was established. To allay the irritability subsequent upon inflammation of the intestinal mucous membrane, and also for its cathartic effect, an emulsion of castor oil was administered in large doses three times daily. Two days after commencing to use the emulsion, the woman experienced pains, which she described as similar to those of the first stage of labor. The result was the expulsion of an enormous mass of excrementitious matter, hard and firm in texture, with a groove along its surface, furnishing imprinted evidence that it had been expelled from the transverse colon.

After the evacuation of the mass, there was a complete and instantaneous cessation of the asthma, which, up to that date, had resisted all medical treatment. It is therefore clear that the asthma was due to the chronic and extensive faecal accumulation. The patient has had no recurrence of asthma up to the present time. Yours truly,

P. C. JENSEN, M.D.

Chicago, Ill., November 23, 1887.

—Mr. Lawson Tait has been appointed Professor of Gynecology in Queen's College, Birmingham. Dr. John Clay will continue to lecture on midwifery.

NOTES AND COMMENTS.

Blue Pus.

The cause of the blue coloration of pus, which is sometimes noticed, has been a matter of speculation for some time. In a communication to the 60th Congress of German Naturalists and Physicians, in September, 1887, M. Ledderhose states (*Gazette Médicale de Paris*, November 5, 1887) that his primary object in investigating the subject was to determine the chemical constitution of the coloring matter of blue pus. The empirical formula $C_{14}H_{14}N_{20}$, which he has found, corresponds to that of a body of the aromatic series.

This coloring matter, *pyocyanine*, when injected under the skin in the form of the hydrochlorate, and in pretty large doses, does not give rise to toxic symptoms in frogs and pigeons. Cultures of the bacillus which secretes it only contain some metallic plates in the most superficial layers. The bacillus seems to find the elements necessary to the formation of the coloring matter not in the pus, but in the neighborhood of the skin, possibly in the ammoniacal sweat. Pflügge and Fraenkel do not think that the bacillus in question is the cause of the blue pus; but M. Ledderhose maintains that it is, and details some experiments tending to prove it.

The Spread of Leprosy.

With reference to the case of leprosy resulting from vaccination, which was communicated to the *British Med. Journal*, June 11, 1887, and contained in the COMPENDIUM OF MED. SCIENCE, July, 1887, J. D. Hillis, late superintendent of the British Guiana Leper Asylums, writes to the *British Med. Journal*, Nov. 5, 1887, that in the West Indies there is a widespread belief in the propagation of leprosy by vaccination, and that both white and colored classes are particular to have their children vaccinated only with lymph imported from England. In his work on leprosy, Mr. Hillis has recorded a case of confirmed tuberculated leprosy supposed to have been contracted by vaccination, although he has no doubt himself that it actually was so contracted. He says in his book: "I have already given some cases in which there could be no reasonable doubt but that the disease was produced by vaccination with tainted lymph, and we have testimony in favor of this mode of propagation from such men as Tilbury Fox and Erasmus Wilson."

Mr. Hillis says he has taken great interest in the subject of the spread of leprosy. Since

the report of the Royal College of Surgeons in 1867, more light has been thrown on the pathology of the disease, and a mass of valuable information collected. It is also known that many medical men differ from the college in the opinion then expressed with regard to the contagiousness of leprosy. From all parts of the world intelligence comes of the increase of leprosy. Is the cause of this satisfactorily accounted for on any other hypothesis than that of contact of the unhealthy with the healthy? Mr. Hillis says he has had more than twenty years' experience of the disease, one-half of the time as superintendent of the largest leper asylum in the West Indies, and his opinion is that leprosy, in some manner yet unknown, is thus communicated, and that whenever lepers are allowed to congregate, and no attempt made at isolation, other cases will in due course assuredly arise, irrespective of hereditary tendency, peculiarity of diet, locality, etc.

He then cites the following cases: A shopkeeper at Demerara, whose business as contractor for provisions took him frequently to the asylum, became leprosy. For at least ten years his wife remained free from any sign of leprosy. The case was well-known, and Mr. Hillis had been frequently called on to explain with reference to this very person, how, if leprosy was in any way contagious, this man's wife escaped so long. In May, 1886, this woman came to him with well-marked symptoms of leprosy, and was under treatment when he left the West Indies.

The Opium Habit in San Francisco.

Dr. Winslow Anderson, of San Francisco, in a letter to the *Medical Record*, November 5, 1887, says that opium smoking and morphine eating are alarmingly prevalent in that city. Women, as well as men, are the slaves of the habit. A large proportion of the *demi-monde* of San Francisco and the poorer slaves of this drug smoke the "Chinese pipe." It is really surprising how many *habitués* visit the Chinese "dens" and opium "joints" daily. Dr. Anderson has witnessed the sickening sight of young white girls from sixteen to twenty years of age lying half-undressed on the floor or couches, smoking with their "lovers." Men and women, Chinese and white people, mix indiscriminately in Chinatown smoking houses. Another class of people purchase their "lay outs," or smoking paraphernalia, and entertain this fiend in their own quarters. Smokers "hit the pipe" once, twice, or three times daily. Morphine eating and morphine injections are perhaps even more frequently

resorted to. Some are equipped with hypodermic syringes and solutions of morphine made by themselves, as the standard Magendie's solution is not strong enough. Injections are used regularly every day, with occasional debauches. Enormous quantities of morphine are consumed in this way and by eating it—ten to twenty grains daily for each individual. It has been estimated that there are about ten thousand *white* opium smokers in San Francisco alone. It is next to an impossibility to determine the number of morphine eaters and morphine injectors, as these people belong to the wealthiest families and are screened from observation. Dr. Anderson says that in one patient, a young lady who for several months suffered with pleuritic effusion of the right side, morphine powders had been prescribed by her physicians to be used *pro re nata*. The habit grew upon her, and for seven years she had used one and two one-eighth ounce bottles of the sulphate of morphine a week—ten to twenty grains daily. This patient was finally cured by gaining her confidence, and by the judicious use of diminishing doses of morphia, combined with good sanitary surroundings and a stimulant and tonic course of treatment.

Ménière advises the use of the following for pruritus of the vulva:

- R Zinc. oxid. 1½ drachms
 Potas. bromid. 2½ drachms
 Ext. cannabis indic. 30 grains
 Glycerite of starch. 7½ drachms
 M. Sig.—To be preceded by cold bathing.

Dr. Huchard recommends the following formula for the treatment of flatulent dyspepsia:

- R Salicylate of bismuth. 2 parts
 Calcined magnesia. 2 parts
 Powdered willow charcoal. 3 parts
 Oil of anise. 1 part
 M. Sig.—Of this powder a small teaspoonful may be taken an hour or half hour before a meal.

Chloride of Ammonium in the Treatment of Diseases of the Liver.

Surgeon General W. Stewart, in a communication on this subject to the *Lancet*, October 22, 1887, refers to a former communication of his in which he showed that, in hepatic congestion, a local depletion of the portal capillaries is effected by each succeeding dose of chloride of ammonium, and that this depletion, unlike that obtained by other measures, was not attended with depression. After stating that, with the exception of Pro-

fessor Aitken, the other men in England who had used the treatment, had not given the necessary attention to diet and management, without which successful results could not be obtained, he proceeds to detail the characteristic symptoms produced by the drug in hyperæmia of the liver. These symptoms occur shortly after the medicine is taken, in from five minutes to half an hour. Sometimes a shock is felt, as if "something gave way" in the side; at other times a succession of shocks is experienced in the hepatic region, accompanied or not by a prickling sensation ("pins and needles"), or as if cold water were trickling down the side; or the action is described as that of "pulling" from one hypochondrium to the other, or from the margin of the right costal arch upwards and backwards, as if through the liver; or a "clawing," "working," or "gnawing sensation" is spoken of as felt by the patient. With the local actions excited in the liver and related parts, motor impulses are similarly communicated to the muscles of the intestinal canal, thus increasing peristalsis.

In addition to the administration of the drug, the patient should be put to bed, and should have a urinal or bed-pan constantly at hand. No solid food should be given; and wine, beer, or other alcoholic stimulants must be strictly prohibited. Small quantities of milk and beef tea are recommended, and the free use of barley water, as a drink. If diarrhoea exist, a pill of two grains of mercury, and three grains of Dover's powder, repeated every two hours until four or five are taken, will be found the most effectual means of checking it without the risk of setting up gastro-intestinal irritation. Looseness of the bowels does not, however, contra-indicate the chloride of ammonium. The only thing which contra-indicates the immediate use of the drug in acute cases is the existence of a combined hot and dry state of the skin, with pyrexia. Under such circumstances, its use should be preceded by a few small and frequently repeated doses of solution of acetate of ammonium, till the skin is rendered moist. Fomentations or hot bran-bags applied to the seat of the pain in the side will be of use in aiding determination to the skin generally.

The author gives the drug in doses of twenty grains three times daily.

—There is a mind cure medical college in Rutland, Vt., which issues diplomas. Its graduates can use the letters M. D. after their names, and say that they mean Mind Doctor.

Evil Effects Produced by the Corset.

In a paper in the *N. Y. Medical Journal*, which is unique in the scientific way in which the subject has been presented, as well as in the character of the illustrations, Dr. R. L. Dickinson, of Brooklyn, lecturer on obstetrics in the Long Island College Hospital, discusses the old question of the corset, and the ill-effects produced by it, with reference to pressure and displacement. His method of study is the following: An inelastic bag is connected with a manometer in such away that when the bag is held on a level with the fluid in the tubes of the manometer the, latter registers zero. The bag (kept at the zero level) is introduced beneath the corset, which is then closed, and the readings are made. Two inches of mercury displaced, *i. e.*, an inch on each side, will signify a pound of pressure to the four square inches of bag surface. To obtain the number of pounds pressure on one square inch of surface, the reading is divided by eight. Without presenting the results of his studies in detail, the following are his conclusions, briefly stated:

"1. The maximum pressure at any one point was 1.625 pound to the square inch. This was during inspiration. The maximum in quiet breathing was over the sixth and seventh cartilages, and was 0.625 pound.

"2. The estimated total pressure of the corset varies between thirty and eighty pounds—in a loose corset about thirty-five pounds; in a tight corset sixty-five pounds.

"3. Within half a minute after hooking the corset such an adjustment occurs that a distinct fall in pressure results.

"4. The circumference of the waist is no criterion of tightness. The difference between the waist measure with and without corsets gives no direct clew either to the number of pounds pressure or to the diminution in vital capacity. Relaxation and habit seem to affect these factors largely.

"5. The capacity for expansion of the chest was found to be restricted one-fifth when the corset was on.

"6. The thoracic character of the breathing in women is largely due to corset-wearing.

"7. The thoracic cavity is less affected by the corset than the abdominal.

"8. The abdominal wall is thinned and weakened by the pressure of stays.

"9. The liver suffers more direct pressure and is more frequently displaced than any other organ.

"10. The pelvic floor is bulged downward by tight lacing one-third of an inch (0.9 cm.)."

A Plea for Calomel in Diseases of Children.

Dr. George B. Fowler, Professor of Clinical Medicine in the New York Postgraduate School of Medicine, in an article on the value of calomel in certain diseases of children (*Medical Record*, November 19, 1887), sums up his opinion as to its value in the following words: "I claim for calomel that it is the best and most agreeable cathartic for children; that it is a markedly antiseptic and tonic medicine; that it is an effective diuretic; that it promotes dissolution of fibrinous formations, whether they be interstitial, or whether they be membranous deposits upon mucous membranes."

Is Leprosy Contagious?

In a letter to the *Medical News*, November 26, 1887, S. P. Armstrong, M.D., P. A. Surgeon U. S. Marine Hospital service, says: I would offer an amendment of Terence's familiar line—*Medicus sum: medicini nihil a me alienum puto*—as my apology for trespassing on your columns in this case of Dr. Van Harlingen (whom I have not the pleasure of knowing), some cases of leprosy he was treating, and the Board of Health of your city, Philadelphia.

I learn from the reports in the daily newspapers of this city, that the health officer of Philadelphia had insisted upon the removal and isolation of some cases of leprosy which were under the care of Dr. Van Harlingen. It would seem, from the action taken, that leprosy is regarded by the health authorities of Philadelphia as somewhat more contagious than small-pox, or the other exanthemata, and consequently I would offer the following in testimony against such an idea.

In 1880 a case of leprosy was admitted into the U. S. Marine Hospital wards at Hotel-Dieu, New Orleans. Subsequently the case was transferred to the U. S. Marine Hospital at Mobile. He was exposed to other patients, subjected to no rigorous quarantine or isolation, and no case developed among other patients.

I have often seen, during the years I was on duty in New Orleans, cases of leprosy in the Charity Hospital of that city. On referring to the reports of that institution it may be found that, in 1885, there were of the different varieties of leprosy, six white and one colored patient treated. In 1884, two white persons were treated. In 1883, two white and one colored patient. In 1882, four white patients. In 1881, four white and one colored patient. The cases are treated in the hospital wards.

While on duty in Key West, Florida, in 1883, I treated a case of tubercular leprosy in a mulatto child, no isolation being considered.

In the report of the Louisiana Board of Health for 1880, Dr. Joseph Jones has a paper on leprosy in Louisiana, and, though president of the Board of Health, does not insist upon the exclusion authorized by Biblical law.

At any rate, it does not seem that the public alarm, and consequent unjust criticism of a professional man, are warranted by the lack of evidence regarding the existence in the United States of the environment, race dyscrasia, and other genetic factors which have served to make this disease the scourge of certain localities.

Hemorrhage from Traumatic Rupture of Varicose Veins of the Vulva.

In the *Progrès Médical*, November 12, 1887, T. Legry reports the case of a woman, six months' pregnant, who fell upon the partition bar in a traveling coach, striking upon the vulva and rupturing some slightly varicose veins just within the vagina on its posterior wall. Hemorrhage was exceedingly profuse, so that the patient was nearly in collapse. An examination was made, but no placenta, nor presenting part of the foetus, nor any other source for the hemorrhage could be detected. The hemorrhage was controlled by tamponading the vagina. On the day following the accident, the source of the hemorrhage was discovered; and, two weeks after the accident, a dead foetus was expelled entire.

A "Regular" Charlatan.

The *St. Louis Med. and Surg. Journal* is very indignant for the following reason: Some months ago a merchant of that city consulted a physician concerning a gastric and intestinal trouble, which was manifestly the result of over-indulgence in food and drink. The doctor so told his patient in plain words and advised abstinence and a simpler diet, charging for the consultation (which lasted nearly an hour in the busiest part of the day) five dollars. The patient objected, but paid it. A few weeks later the doctor, while in Philadelphia, met at his hotel the same merchant, then on his homeward way, and incidentally learned that the latter had while "East" consulted a celebrated New York doctor, who "had diagnosed his case perfectly, and had prescribed medicines to cure it." The merchant was in a patron-

izing mood and graciously informed the St. Louis doctor that he would let the latter see Dr. —'s prescriptions and letter of directions, as it might be of some service to him in future emergencies. The first impression was, to refuse, but curiosity got the better of the wounded professional pride, and the doctor consented to accompany the merchant to his room and take a lesson in medicine. Once there the merchant opened a package about fourteen inches long and ten inches square, bound with a shawl strap, and took out two pint bottles of "tonics," an immense box containing five hundred capsules, two homœopathic vials containing pellets, a spraying apparatus and a number of miscellaneous boxes of pills, powders, etc. The "letter of instructions" contained minute directions for taking these remedies, and but little else.

"Where are the prescriptions?" asked the doctor; and in reply was told that the druggist had kept them "so that he can refill the bottles when they are empty."

"And you expect to take all this stuff and send back for more! And may I ask," said the St. Louis doctor, "what all this precious stuff cost you?"

"Well, Doctor — charged me twenty dollars. The druggist's bill was \$8.60."

Without prolonging the interview the doctor bade his quondam patient good day and retired to ruminate over the strange and unaccountable love for humbuggery and deceit which possesses the majority of human beings. *N t populus, but homo, the genus man, vult decipi. Decipiatur!*

Dr. Rabow, in *Therap. Monatshefte*, No. 8, 1887, recommends the following formulæ for the use of terpine and terpinol in diseases of the respiratory and genito-urinary organs:

- R Terpin. hydrat. gr. cl
Alcoholis. f 3ivss
Aq. destill. f 3iij
M. S.—Teaspoonful dose.
- R Terpinol.
Sodii benzoat. āā gr. xv
Sacch. alb. q. s. ut fiant pil. no. x.
Sig.—One pill every three or four hours.

—Milan, Italy, is suffering from an epidemic of small-pox, which has for the most part attacked the non-vaccinated, but to a smaller extent also those who were imperfectly vaccinated. To the former class belong the infant victims; to the latter the aged. The vaccination committee are urging that vaccination be made compulsory.

News Items.

—The Hall of Anatomy of the University of Virginia was opened on October 25, with an address by Dr. Paul B. Barringer, of Davidson College, N. C.

—Small-pox has broken out in the Pantin and Aubervilliers districts, Paris. The hospitals are full of patients. The disease originated among German residents.

—Dr. C. T. Parkes, formerly Professor of Anatomy in the Rush Medical College, Chicago, has succeeded to the chair of surgery made vacant by the death of Dr. Moses Gunn.

—Dr. William Pierson, the senior physician at St. Michael's Hospital, Newark, has been elected by the Board of Trustees to succeed Dr. O'Gorman as medical director of the hospital.

—The Governor of Pennsylvania has appointed Dr. George McLeod, a homœopathic physician of Philadelphia, a member of the Board of Public Charities, in place of Dr. J. K. Lee, deceased.

—Diphtheria is prevailing to a considerable extent near Westchester, N. Y. Several deaths have occurred within the last two weeks. The Board of Health has decided to close the public schools until the epidemic is over.

—The New York Cancer Hospital was opened on December 6. The building is the gift of Mrs. John Jacob Astor, who gave \$200,000 for its construction, and her husband and other wealthy persons have added to the endowment.

—The fatal cases of diphtheria about Green Creek, Cape May county, are now thought to have been caused by stagnant water collected about the mouth of Foster's Creek. Means are being taken to drain the meadows, money having been raised by private subscription to meet the expense.

—The Mount Auburn Children's Hospital, in Cincinnati, the gift of the Emory brothers, was dedicated Nov. 23. The buildings will accommodate fifty beds. "While the management is entrusted to the Protestant Episcopal Church, the patients are to be children under 15 years of age, without regard to color, creed or nativity."

—The Board of Health of Philadelphia, on November 15th, adopted a report relative to the proposed removal of the Municipal Hospital to the Lazaretto, on the river Delaware, below the city. The report opposes

the change for these reasons: The legal objection to the location of a hospital for contagious and infectious diseases in an adjoining county; the complete failure of the experiment in 1863 and 1864; and because of the fact that it is a bad practice to remove the sick a long distance; the unsuitableness of the Lazaretto for a hospital of this character, and the impropriety of locating a pest house at a quarantine station.

—Poisonous perambulators, says the *British Medical Journal*, are probably one of the least suspected of dangers, yet, nevertheless, one which experience has shown to exist, and, therefore, one against which the parents of a family would do well to be on their guard. A case is recorded this week of a child, aged four months, who, on its return after being out under a hot sun, was seized with sickness and vomiting, the vomited matter being a green-colored fluid. From inquiries made by the medical man it was elicited that the child had been seen to suck a green strap of the perambulator, and the true cause of the mischief was at once suspected, namely, arsenic poisoning. An analytical examination of the strap confirmed this view, arsenic being found to be present in great abundance. In spite of all that medical aid could effect, the child gradually sank from exhaustion.

—About two months ago, a young man named Palmer shot himself in the head, the bullet entering just over the left eye, and lodging in the brain. From the time of the shooting to the time of his death he did not regain full consciousness. The case is remarkable as to the length of time the patient survived. At the time an operation to remove the ball was deemed impracticable. A probe was introduced into the wound and found its way some distance into his head, and it was decided to wait for further symptoms of brain trouble, which would indicate the advisability of the operation. Secondary brain symptoms developed, but the patient was at no time in a condition to warrant the use of the knife.

Every attention which medical skill could give was shown the patient, who survived eighty-five days, and died Nov. 22, 1887.—*Times*, November 24, 1887.

—There is nothing like a little healthy criticism at the opportune moment, especially in matters directly pertaining to the public interests, in proof of which reference may be had to the recent strictures of the Philadelphia doctors upon our defective quarantine system, which, notwithstanding the feeling created among the officials here, are

beginning to bring forth good fruit. It has stirred up not only Mr. Health Officer Smith and President Baylis, of the Board of Health, but the Mayor himself, to see what could be done to accomplish the very reforms which the Philadelphia doctors' committee recommended, but which at the time were not taken in as friendly a part as they ought to have been. Mr. Hewitt, in addressing the Health Board on the subject, asks the President to communicate with the Academy of Medicine, in order to secure their cooperation in all matters pertaining to contagious and infectious diseases; also to request them to make an early examination of the quarantine establishment, and to point out its defects and requirements, in order to bring it up to the highest ideal standard of modern scientific and medical knowledge.—*Correspondence in Public Ledger*, November 16, 1887.

—An unfortunate incident has occurred at the General Hospital, Vienna, which has ended in the dismissal, by ministerial decree, of Dr. Lustgarten from the post of assistant to the Professor of Dermatology, Dr. M. Kaposi. Dr. Lustgarten is a young man who is already favorably known for his scientific work; his name must be familiar to many in connection with the discovery of the syphilococcus, the supposed parasitic agent in the transmission of syphilis. The occurrence has, as may be supposed, caused much excitement in professional circles in Vienna. The following appear to be the facts of the case: Professor C. Böhm, who was not long ago appointed Director of the General Hospital, in the place of Dr. Hoffman, has shown a good deal of the activity popularly associated with "new brooms," with the result that there has been considerable tension in his relations with the resident medical staff. Dr. Lustgarten, wishing to have a patient transferred from the skin department to the surgical wards, sent one of the hospital servants to the director with one of the tickets required in such cases, for his signature. The director, however, sent the servant back to Dr. Lustgarten with the ticket, on the ground that it had not been properly filled up. The man, who, like nearly all of those in the service of the hospital, bore a grudge against the director on the score of his alleged undue severity, delivered the message in a way that Dr. Lustgarten considered grossly insulting. On the spur of the moment he wrote an injudicious letter, which he sent to Dr. Böhm by the same man. The director thereupon forwarded the letter, without any comment or explanation, to the Minister of Education,

who immediately dismissed Dr. Lustgarten. Without wishing to pronounce a critical judgment on this unfortunate incident, we may be allowed to express the hope that this regrettable occurrence will not prove a serious hindrance to a career so full of promise.—*Brit. Med. Journal*, October 26, 1887.

Items.

—The *N. Y. Tribune*, Nov. 24, states that a woman named Mrs. A. B. Kidder has become demented, it is claimed, through the nummery of Mrs. Anna Johnson, a faith-cure or "Christian Science" doctor. Soon after Mrs. Johnson's arrival in Chicago, about two months ago, Mrs. Kidder, not being in good health, called on the woman, and, becoming infatuated with the treatment, dismissed the family physician and kept on with Mrs. Johnson. The husband is very indignant, and says he will appeal to the State Board of Health and see if such quacks and frauds cannot be prevented from doing the mischief they are doing.

—The *British Medical Journal* describes a new method of testing for morphine, capable of detecting the presence of so small a quantity as $\frac{1}{200}$ grain. A few drops of strong sulphuric acid are added to the solution, together with about the same amount of a solution of sodium sulphate (strength not stated). The mixture is heated in a porcelain capsule, and, as soon as it begins to give off sulphuric vapor, it is suddenly cooled, when, if morphine is present, it will assume an intense violet color. If it is further heated, it turns brown, and, after it is cooled, the addition of a few drops of water produces a vivid red color, which changes to a pale green on the addition of more water. If, now, an equal bulk of chloroform is added, and the mixture well shaken, the chloroform becomes of a bright blue color.—*Phar. Record*.

—In the Pitti Palace, at Florence, is a table, says the *Medical Press*, which for originality in the matter of construction and ghastliness in conception, is probably without a rival. It was made by Giuseppe Sagatti, who passed several years of his life in its manufacture. To the casual observer it gives the impression of a curious mosaic of marbles of different shades and colors, for it looks like polished stone. In reality it is composed of human muscles and viscera. No less than a hundred bodies were made use of for the material. The table is round, and about a yard in diameter, with a pedestal and four claw feet, the whole being formed

of petrified human remains. The ornaments of the pedestal are made from the intestines, the claws with hearts, livers, and lungs, the natural color of which is preserved. The table-top is constructed of muscles artistically arranged, and it is bordered with upwards of a hundred eyes, the effect of which is said to be highly artistic, since they retain all their lustre and seem to follow the observer. Sagatti died about fifty years ago. He obtained his bodies from the hospitals, and indurated them by impregnation with mineral salts. To add to the horror which such a piece of furniture is calculated to inspire in the minds of most people, the fate of Count Rittaboca, its last owner, may be related. One Christmas Eve he and his friends were playing cards on this table, when suddenly he jumped up, pale and agitated, overcome by the fixed gaze of these petrified eyes. Yielding to a sudden attack of violent mania, he stabbed himself and fell upon the table. His heirs, as may be imagined, were very pleased to sell this funeral object to the Government, who installed it in its present situation.—*Boston M. and S. Journal*.

Humor.

—*The Story of a Prescription*.—A druggist tells this story at his own expense. Said he: "A man came in with a prescription, and I noticed that the paper did not bear the name of any physician. I called the customer's attention to it, and he replied that he knew 'all about who wrote this prescription. Never mind,' said he, 'who wrote it. The doctor signed his name and I cut it off.' 'What did you cut it off for?' I asked eagerly. 'So that I wouldn't have to pay you his commission,' was the innocent response. I then tacked on fifteen cents extra for luck, but gave him a glass of soda with a wink in it, and he walked out with an air of a man immensely tickled at the success of his scheme."—*Boston Gazette*.

OBITUARY.

DR. THEODORE R. VARICK.

Dr. Theodore R. Varick died Nov. 23 at his home in Jersey City. On Nov. 17, the doctor fell down stairs and broke his right ankle. He got up for the first time since the accident, Nov. 23, and stepped upon his injured foot. The shock brought on paralysis of the heart and he died in about ten minutes.

Dr. Varick was one of the most prominent surgeons in Jersey City. Appointed Brigade Surgeon-General by Governor Randolph in

1869, he resigned last year. He was President of the Board of Health of Hudson County, a Director of the Board of Managers of the Morris Plains Insane Asylum, Chief of the Surgeon's Staff of the Jersey City Charity Hospital and Medical Director in St. Francis's Hospital.

DR. HENRY D. HARVEY.

Dr. Henry D. Harvey, a promising young physician of Philadelphia, died in his 31st year, Nov. 28, 1887. He was graduated at the University of Pennsylvania in 1878, and subsequently was House Physician at the Episcopal Hospital.

DR. C. LYNDE.

Dr. C. Lynde, aged 70, died on November 25, at Oskosh, Wisconsin, after a brief illness. He was a prominent member of the State Medical Society, and had resided in Oskosh nearly half a century. He had a wide acquaintance throughout the State.

DR. THOMAS L. JANEWAY.

Dr. Thomas L. Janeway died at Eureka Springs, Ark., on Sunday, November 27. He left his home in New Brunswick, N. J., with his brother and sister, on the way to California for the benefit of his health. He was born in 1844 and was graduated at Rutgers College in 1866. He went to Germany and there studied medicine, being at one time a surgeon in the German army, and did not return to New Brunswick until 1877.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Nov. 27, 1887, to Dec. 3, 1887:

So much of S. O. 235, A. G. O., October 8, 1887, as relieves Lieutenant-Colonel Charles T. Alexander, Surgeon, from duty at St. Louis, Mo., and directs him to report for duty at Fort Meade, Dak., is amended so as to take effect Jan. 1, 1888. S. O., 274, A. G. O., Nov. 25, 1887.

Capt. H. P. Birmingham, Assistant Surgeon. The leave of absence granted by orders No. 52, Fort Myer, Va., Nov. 24, is extended 23 days. S. O. 255, Div. Atlantic, Nov. 28, 1887.

There have been no Changes in the Medical Corps of the U. S. Navy, during the week ending Dec. 3, 1887.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for three weeks ended Dec. 5, 1887:

Walter Wyman, Surgeon, granted leave of absence for 30 days, Nov. 29, 1887.

L. L. Williams, Assistant Surgeon, granted leave of absence for 21 days, Nov. 18, 1887.

J. J. Kinyoun, Assistant Surgeon, leave of absence extended 7 days, Nov. 29, 1887.

R. M. Woodward, Assistant Surgeon, granted leave of absence for 17 days, Dec. 5, 1887.

ORIGINAL DEPARTMENT.

CLINICAL LECTURE.

DELIRIUM TREMENS.

BY WESLEY M. CARPENTER, M.D.,
Professor of Clinical Medicine in the University of
the City of New York.

Gentlemen:—The patient before us represents a class of cases of considerable interest. His name is John B.; he is forty-two years of age, and a native of Ireland; he has been in this country about twenty years, and his occupation is that of a teamster. It will be noticed at once that the man shakes a good deal. He cannot keep still. When he puts out his tongue, notice the trembling; it is also coated. He says he cannot sleep, and when he closes his eyes he sees living objects, such as cattle, horses, dogs; and “last night a woman came out, dressed all in red, with her hair flying.” Continuing with his history, we learn that he has been drinking liquor the past month pretty freely. Prior to that he had abstained from drinking for about seven months. That is to say, the man is not a constant, but a periodic drinker. He thinks that during the past month he has drunk about two pints of whiskey a day. But it was not until after he reduced the quantity, after he began to break off, that he commenced to suffer from this tremulousness. Still, this point in his history is not very clear; we are unable to learn with certainty whether the uncomfortable sensations, from which he has suffered during the past four days, began after or during the time he was drinking large quantities of alcoholic beverages. That point is one which has given rise

to considerable discussion. We will refer to it again.

Our patient tells us that during the time he was drinking so excessively he had “no appetite at all,” and that his bowels were very loose; the urgency at times was so great that he had “hardly time to drop his pants.” In general terms, there has been gastro-intestinal disorder. He has not vomited.

The three prominent symptoms in this case are: Inability to sleep, tremor and moderate delirium. These are associated with gastro-intestinal disorder, and a direct history of excessive indulgence in alcoholic drinks. Doubtless you have already made a diagnosis. The man is suffering from delirium tremens.

Etiology.—A few words in reference to the etiology of this disorder. It has been claimed by good observers that delirium tremens is caused by the *withdrawal* of alcoholic stimulants, rather than by the direct effect produced by them. But, so far as I have been able to ascertain, the weight of evidence is in favor of the view that the affection is due directly to the effect produced by the alcohol which has been ingested. That view seems to be gaining ground constantly. You can readily understand that the belief entertained on this point will influence the treatment. The fact may be mentioned here, lest it be overlooked when we come to speak of the treatment, that if delirium tremens be the direct result of the use of alcoholic drinks, the most reasonable conclusion is that alcoholic stimulants should be withdrawn at once; but, if it is believed to be due to the withdrawal of alcoholic stimulants, then you would perhaps introduce into your treatment a moderate amount of alcohol.

Symptomatology.—There are a few features in the disease which will enable you to make a diagnosis almost immediately. It will hardly be necessary even to investigate the history of the case, although one should not neglect to do so in order to avoid the possibility of mistake; for it is not every patient who will as willingly tell you his history as this man has done. Sometimes they resort to every resource to hide from you the fact that they have been given to drinking.

There is delirium. Sometimes this is violent. It is usually mild. In this patient it has been very mild. In some cases it is of a pleasurable kind. It may be of the variety, however, which has been called "coma vigil," a form of delirium which occurs in typhus fever. The patients with this form of delirium, it has been supposed, see all sorts of disagreeable figures. The pictures upon the wall and the figures in the wall-paper may be transformed into demons and all that is repulsive. For that reason it has been recommended that these patients be placed in a room, the walls of which are entirely bare; a room in which there is nothing to excite the imagination and disturb the nervous system; nothing which will cause unrest instead of rest.

Another symptom is insomnia. From that, this man has suffered to a marked degree. He tells us he has not slept for three or four nights.

Tremor is a symptom which belongs to this affection, as is indicated in the name: delirium tremens. This symptom has long been recognized as essential, and it has entered into the classical descriptions of the disease. This man's whole body trembles; he can not resist it. His tongue presents the characteristic tremor—tremulousness along the border, and most marked at the tip, where it is in constant motion. Upon these three symptoms, then, you might rest your diagnosis. But there are two other symptoms which should receive special consideration. The one may be regarded as a premonitory symptom, namely, gastro-intestinal disturbance. To illustrate the point, I will cite a case. A man, habituated to the use of alcoholic stimulants, suddenly began to drink to excess, and took from sixty to seventy drinks a day: but claimed that they were small ones. When, however, the little drinks which the man took, say sixty or seventy tablespoonfuls, were added together, it was found that he was taking about a quart of whiskey a day. Very soon after he began to take these frequently repeated doses of whiskey, gastro-intestinal disturbance mani-

fested itself by loss of appetite, a coated tongue, foul breath, and constipation or diarrhœa. In the patient before us, there has been diarrhœa, and of so urgent a nature that he has scarcely had time to prepare for the call. More frequently, the bowels are so constipated that it will be necessary to resort to active cathartics.

The other symptom to which I wish to call your attention is a negative one: viz., the temperature which, as a rule, is not elevated. When pyrexia is present, it indicates a complication. The complication which occurs most frequently in delirium tremens is pneumonia; and the most common location of the pneumonia is at the apex. But there may be other complications, as pleurisy, pericarditis, etc. When pneumonia is present, it may not be recognized from rational symptoms. The diagnosis must be based upon the physical signs. Hence it should be the rule, in cases of delirium tremens, to examine the chest at regular intervals. Indeed, it ought to be examined every day, if we would detect early any pulmonary complication.

Treatment.—One of the first indications is to see that the patient is properly nourished. This you may not be able to accomplish at the outset. In the case before us there is an obstacle to proper nutrition, and that is gastro-intestinal disturbance. So also in cases in which constipation with marked impairment of appetite are prominent symptoms, you will be obliged first to remove these before food can be properly retained and assimilated, and you may succeed in preventing the full development of delirium tremens by giving the patient early an active cathartic. For this purpose there is nothing more effectual than calomel. Give the man ten grains of calomel and fifteen grains of bicarbonate of sodium, and follow them in four hours with Seidlitz powders or sulphate of magnesia, until the patient has a free evacuation of the bowels. Or you may administer the compound cathartic pill. If then the patient will take nourishment in the form in which it can be most readily assimilated, as milk, broths, etc., you will frequently be able to prevent the full development of the attack. In the first place, then, endeavor to correct the gastro-intestinal disturbance, and then give nourishment.

The third general indication is to give rest to the nervous system. If now you can keep your patient removed from perturbing influences, and can give him a certain amount of nourishment, you will have fulfilled the indications called for by the theory that the

disease is self-limited, and needs no treatment whatever. Indeed, experience has shown that a goodly number of patients will recover with the fulfillment of these general indications, and without special remedies. Or, just at this point, the desired rest to the nervous system may be secured by a single dose of opium; that is, after the bowels have been unloaded and the patient has been induced to take nourishment.

An excellent plan of treatment for these patients is to seclude them, feed them, and weary them by walking until they fall asleep. To carry out this plan properly, the patient must have the right kind of attendants. They must be kind and resolute; gentle and unyielding. But this plan cannot be adopted in a large proportion of cases.

At the present time, the remedies which are most commonly used for the purpose of giving rest to the nervous system are the bromides and the hydrate of chloral. One mode of using the bromides, either potassium or sodium—many preferring the latter because it is less likely to disagree with the stomach than the potassium salt—is to administer twenty grains every twenty minutes until four doses are taken, and follow with twenty grain-doses every two or three hours until sleep is obtained.

The hydrate of chloral may be combined with a bromide. It is commonly so given, and in doses of from six to ten grains or more, every two, three or four hours. But it should not be forgotten that this drug sometimes produces fatal coma, and in some of these cases post-mortem examination has revealed chronic disease of the kidneys, in some of its forms, to the existence of which those addicted to the use of alcoholic drinks are especially liable.

Nearly thirty years ago the method of treating delirium tremens by the administration of large doses of the tincture of digitalis was brought forward, and it is regarded by a considerable number of practitioners as the best that can be employed. This drug has been given successfully in a large number of cases, in doses of one drachm of the tincture every two hours. It is best to unload the alimentary canal, before beginning with the digitalis, and, so far as I have been able to ascertain, no disagreeable effects have been produced by the drug. I have a case in mind, that of a patient who received so much benefit from the use of this remedy in warding off a full attack, that his friends kept the tincture of digitalis on hand and gave him teaspoonful doses at once on the appearance of the premonitory symptoms. A number of times sleep was

induced in this way, and the attack, as it were, aborted.

The administration of capsicum in large doses was at one time a somewhat favorite method of treating delirium tremens, but the plan has substantially fallen into disuse. As to treatment by the use of alcoholics, the indications have already been given, and I would recommend to you not to employ them.

The question of physical restraint may be one which you will be obliged to meet. In a large proportion of cases in private practice the friends will be able, without resorting to force, to keep the patient within proper limits. But you will occasionally encounter one in which something more may be required. If it becomes necessary to pinion the limbs, do it with *broad bands* which will not materially disturb the circulation. Do not use cords. Here I show a belt to which are attached iron hand-cuffs, which seems like an unnecessarily harsh way of imposing restraint upon these unfortunates, and yet they are such as are used in some of our public institutions. The body can be effectually secured by a broad band of strong cloth, if leather cannot be readily obtained, and the arms and the legs can be restrained in the same way, so that the patient cannot do himself harm.

These, gentlemen, are some of the practical points in the management of a case of delirium tremens. Of the methods which have been mentioned, that at the present time most frequently employed is the use of the special remedies—the bromides and the hydrate of chloral. The other methods, however, may do you excellent service, and should not be overlooked. The adaptation of the method to be employed to all the surroundings of the case is an important factor in the successful practice of medicine.

HYDROPHOBIA.

BY JAMES T. WHITTAKER, M.D.,

Professor of the Practice of Medicine, Medical College of Ohio; Physician to the Good Samaritan Hospital, Cincinnati.

Lecture delivered Saturday, Dec. 3, 1887.

Professor Whittaker stated to the class that he would now present to them a case of hydrophobia which had been brought in the night before. He would ask the class to pay no attention to what he would say in the presence of the patient, as he was endeavoring to dissuade him from the idea that he

was suffering from this disease, because the element of fear was a very bad thing in such cases.

The patient was then brought in on a chair and kept in the arena for a quarter of an hour, in full view of the students, where every one of his hundreds of movements and expressions could be carefully observed. The patient was then removed.

Dr. W. A. Holden, house physician, then read the following history of the case:

Mr. S. Dietrich, aged 52, farmer, of Camp Creek, Pike county, Ohio, came into the hospital at 6 P.M. yesterday, December 2. Forty-five days ago a pet spaniel struck him on the lip with his mouth, in caressing him, and caused a slight abrasion, which bled slightly. The wound healed and passed unnoticed, and at the present time scarcely a trace is seen, and the spot is not tender. The dog had acted queerly before the accident, and five days later lay in a comatose condition and died.

Mr. Dietrich continued at his work with his usual health till the morning of day before yesterday, when he was employed butchering hogs; he inhaled some smoke and steam, which caused an attack of dyspnoea. At noon he attempted to drink some coffee, but was unable to do so, and the attack of dyspnoea recurred. Later in the day the attack came on again, and became more frequent through the night. Several hypodermics were given before morning, and the attacks became more infrequent. Friday he ate a small piece of toast, but was unable to drink. The spasms came on frequently during that day, and chloral and morphia were freely given. When he came into the house he was entirely rational, and the attacks of dyspnoea were his greatest trouble. These came on several times a minute, and brought forcibly into play the accessory respiratory muscles. He also frequently expectorated a frothy saliva and occasionally a viscid mucus. He was neither able to eat nor to drink. A large rectal injection of water was given, followed by an enema of chloral, then a hypodermic of morphia. He was able to keep in bed for a few hours, but the attacks of dyspnoea and spitting up of mucus came on so frequently that it became necessary to put him in a chair. At this time the temperature was normal and the pulse 79. Pharyngeal spasms became more frequent, and the patient made frequent or continuous violent efforts to spit up a viscid mucus, and occasionally threw up some fluid from the stomach. At 2 A.M. the temperature was 101.5°, pulse 90. The

pharyngeal spasms became more frequent and severe, and the pulse at 4 A.M. was 100. He became very restless and the spasms more general. At 9 A.M., for the first time, the patient became very debilitated and the pulse very weak and rapid. During the night he took three teaspoonfuls of coffee; at 11.30 one grain of cocaine and a teaspoonful of water was given by the mouth. He obtained slight temporary relief. Later curare was given. Morphia and chloral had none or but little effect.

Gentlemen:—Did you see what that patient did when I offered him a glass of water? He turned from it with fear and distress. The offer was not so cruel as it seemed, as he had been able to swallow a little water in the house. That has given the name to the disease, hydrophobia. He wants water, he craves water, yet he fears it. When he was coming down here, in his suffering, he grasped a handful of snow, which was to him, doubtless, one of the rarest treats which he has enjoyed for some time. This is undoubtedly hydrophobia. A strong, substantial farmer, 52 years old, who never knew what hysteria was, nor nervous disease, is rather too old to pick it up now. His pet spaniel, of which he was very fond, had strayed from home—an unusual thing for it to do. Then, in a season of sanity, which these dogs sometimes have, returned to his master, who rejoiced at the finding of his pet, was fondling him; and the dog, with those tokens of affection common to them, struck his teeth against the lips of his master, and inflicted the wound which will soon cause his death. The injury was not on the part of the body covered with clothes, where the poison might have been wiped away; but on the bare lip. 60 per cent. of bites on the face prove fatal, 40 per cent. of those on the hand, and only from 20 to 30 per cent. of those occurring on parts covered by the clothing. The exciting cause of this attack may be a sudden noise, a slam of the door, or any sudden impression. In this case, it was an appeal to the senses, and that of smell was the one selected. He was butchering hogs forty-five days after the reception of the injury and inhaled some irritating vapor. He was attacked with dyspnoea. An officious neighbor told him that hydrophobia commenced so. This was a most unfortunate occurrence. Fear has much to do with the aggravation of this disease. Men have had what appeared to be a sure case, and were relieved after seeing the dog in health, and thus being made to know that he was not mad, as they had feared. You cannot deceive this man. All our efforts in

this line have been fruitless. He knows that he has hydrophobia and knows he will die.

The chain of evidence in this case is very complete. The dog lived a few days afterwards and died with hydrophobic symptoms. It is of great importance, in all suspected cases, to keep the dog, and watch it closely. It was not known where this dog got hydrophobia. It was known that there were mad dogs about. Rabies is not confined to dogs, but is also found among cats, foxes and other animals. The history is quite enough in this case to support the diagnosis. The history of the bite was obtained here; but this is apt to be forgotten, especially in the country. Some sudden impression may start it up.

When the patient appeared here last night, his suffering from dyspnoea was intense. This is now largely disappearing. Many of you will probably never see such a case again, nor such spasms of the muscles of deglutition. The symptoms are largely referable to the medulla oblongata. The *post mortem* will discover nothing till we reach the medulla oblongata. You could not mistake or confound this case with anything else. The convulsions are not tonic, as in tetanus; they are clonic. The muscles of the jaws are also not involved. This is not the expression of acute mania; for, between the paroxysms, the mind is clear. It is to be differentiated from one disease, lyssophobia. This is to be differentiated principally on the point of the nervous habits of the individual. We would not find diseased or perverted nerve habits in a sturdy farmer of his age. In hydrophobia, the symptoms do not come in the regular order. We find many trivial ailments which do not properly belong to the disease. This patient has clear conception and excessive hyperæsthesia. A cold draft, which no one else could feel, disturbed him all night last night.

It is very essential to follow up the history of the animal. Hammond reports a case in which a man died and the dog did not bite him at all. The period of incubation is not so long in any disease as in hydrophobia. It varies between eighteen to sixty-four days. This case is about an average. Cases do occur in three, six, twelve, and twenty-four months. In the older literature we have statements of its happening after five to ten years, but we look on these statements with incredulity. We know how a man can inhale the micro-organisms of tuberculosis, which will lie latent for a long time, then assert itself. The fact that the period of incubation is so long, gives great encouragement to preven-

tive treatment. We can cut out the wound, suck out the poison, or apply the ligature if properly located. There is nothing better than fire. Heat an iron white hot and apply it to the surface of the wound. Thorough destruction of the wound is the only hope. We must at all events cauterize the wound; lunar caustic is poor, chloride of zinc is better, fire is the best. Destroy the wound at once: but do not fail to do so if as much as two weeks have elapsed. Pasteur thought he could make the patient used to an attenuated form of virus, and thus keep the disease in check. Pasteur's treatment may prove useful. It is too early as yet to tell what will become of it.

Patients attacked with this disease die in from two to eight days. This man looks as if he would die in twenty-four hours. We can only prove beyond a possible doubt that a case is hydrophobia by inoculation. It is doubtful if a true case of hydrophobia ever recovered.

We can relieve symptoms. This man has received forty grains of chloral by the rectum, then one-half grain of morphia hypodermically; one-half hour later, one-third grain of morphia hypodermically, then five grains of chloral hypodermically, all of which was followed by no effect worth speaking of. This morning one grain of cocaine was put in the œsophagus and throat, then one-third grain of curare. Moerck's preparation was given subcutaneously, which should be repeated every half hour till the dyspnoea is relieved. All the tact of the physician is needed to take the fear from the patient. He should be kept quiet; only those necessarily engaged in attending him should be left about him. Put him in a bed, hung around with curtains, so as to exclude the sound and light. This it is said will retard the convulsions, but does not stop the advance of death. Euthanasia, happy death, is all we can hope to secure in this case.

(The patient died that afternoon, having been in greatest torment for fifty-three hours, during which time neither food nor sleep had come to his relief. No autopsy was permitted, as the patient's brother was with him and took him immediately home. He was also accompanied by his family physician, Dr. O. C. Andre, of Battle Creek, Ohio.)

—The *Gazette Médicale* states that Professor Botkin, of St. Petersburg, has been visiting the principal hospitals of Paris, and has been given an enthusiastic reception by the faculty and students.

ORIGINAL COMMUNICATIONS.

FRACTURE OF THE CLAVICLE.

BY ARTHUR E. SPOHN, M.D.,

CORPUS CHRISTI, TEXAS.

The chest, viewed from any side, has the appearance of an irregular cone: the diameters increasing from above downwards to a plane corresponding with the centre of the sternum. Upon this cone the upper extremities, as it were, hang, through the medium of the scapula and clavicle; which, being bound together by ligaments, rest on the chest like a collar, held in position by the various muscles; the only fixed point being the sterno-clavicular articulation. Fixed at this point, the clavicle on each side serves as a brace to hold the shoulder-joint in position; and, when fractured, the anterior support of that joint is lost, which allows it to droop and be carried downwards, forwards and towards the chest; because the scapula rests on a surface pressing diagonally downwards and forwards, while the broken clavicle, which before held the joint in position, now allows the joint to fall in towards the chest, the ends of the bones generally overlapping. Pressure against the shoulder-joint backwards will carry the scapula back over the same surface upwards and backwards, when the broken bone may easily be replaced; but, from its peculiar position, it is almost impossible to retain it in such a position as to prevent more or less deformity, and at the same time to cause the patient much inconvenience.

The device I have lately adopted is to adjust a splint which shall replace the broken clavicle and restore the lost support to the shoulder-joint. This splint I have called the subclavicular or anterior chest-splint (Fig. 1). It is simply a piece of wood or sole leather made to fit the anterior surface of the chest just below the clavicular bones, two inches wide, and long enough to reach the outer side of each arm (see Fig. 2). This splint should be well padded and covered with strong muslin. Two pads are now made to place under each end of the splint, to fit into what I have chosen to call the lateral triangular space of the chest. Viewing the articulated skeleton from the front, the arms hanging down, there is on each side a triangular space, bounded above by the clavicle, acromion and coracoid processes; externally, the head

and upper third of the humerus; internally, by a line drawn from the centre of the clavicle to the junction of the upper and middle thirds of the humerus. Crossing this space, which, in cases of fracture, draws the

FIG. 1.

joint forwards, downwards, and towards the chest, we have the pectoralis minor muscle.

This space does not show well on the body, but can be distinctly outlined by a little pressure. Firm pressure, directed backwards over a pad in this space, while the arm is in a sling, will thoroughly fix the shoulder-joint and carry it upwards, outwards, and backwards, thus meeting every indication in treating fractures of the clavicle; because the scapula rests upon a surface directed downwards, forwards, and outwards, which course it takes when the anterior support (clavicle) is removed; while firm backward pressure will reverse things and force the scapula over the same surface upwards, backwards, and towards the spine, which must raise the shoulder-joint and increase the space between the acromion process and clavicular notch of the sternum; so that, were the clavicle entirely removed, the shoulder would remain in proper position as long as this support is kept up.

When fractured, the clavicle is practically removed, even worse, and distorted. The subclavicular or anterior chest-splint replaces the broken clavicle; also presses the pad into the triangular space above described, giving the required support.

The pad should be thicker in the middle than at either end (see Fig. 2), so that it

will press well against the outer end of the clavicle, coracoid and acromion processes, and sink in, as it were, between the upper part of the arm and side of the chest, thus forcing the shoulder-joint outwards. The pad should now be firmly stitched to the splint and a figure-of-eight bandage applied, first putting a little cotton or, better, a small pad under each arm; place the arm in a sling, when the dressing is complete (Fig. 1, *c*, *d*).

In order to appreciate this dressing, see Fig. 3, showing the relation of the figure-of-

FIG. 2.

eight bandage to the scapulæ. The surface on which the scapula rests is directed upwards and backwards; consequently this bandage carries that bone upwards and backwards, elevating the shoulder-joint; while the anterior splint, thus held in position resting on an inclined plane, supports the front of the shoulder and restores, as it were, the broken clavicle, while the patient is put to very little inconvenience: he can walk about or lie down with perfect safety. The dressings must be thoroughly stitched together.

I have, during the past few months, treated several cases in this manner, and with better success than I ever saw by other appliances; sometimes simply placing the splint under a tight-fitting vest (Fig. 4), with the arm in a

FIG. 4.

sling, and the vest sewn or pinned to the splint.

PHYSICIAN AND PHARMACIST.

BY W. C. EUSTIS, M.D.,
FARMINGTON, MINN.

I have been engaged in the active practice of medicine a little more than ten years. At first I sent all patients with a prescription to the druggist to be filled by him. For the past seven or eight years, however, I have dispensed all of my own drugs, and could not be induced to do otherwise, for patients prefer it, and so does the doctor. In the first place the profit demanded by most druggists is exorbitant: for instance, I went to the druggist for a bottle of beef, iron and wine (1 lb.) for a patient, and was charged one dollar and fifty cents for the bottle, and yet the same article could be bought at wholesale for less than fifty cents per bottle. Just think of it, one dollar profit on so simple an article already compounded. One day every one capable of compounding drugs at one of our pharmacists was absent, and I was asked to compound the prescriptions, and, on asking different individuals what they paid before, was shocked to find that in many instances they had paid eighty cents for three cents worth of medicine, and a bottle costing the same; the water cost the druggist nothing. Other prescriptions that I filled were on a par with the above so far as the profit was concerned. In no instance did it require longer to fill a prescription than from five to ten minutes, and no special skill. The profit in some instances exceeded the charge made by the doctor for the prescription. No

wonder that most people dread going to a doctor because of the expense, and especially at the druggist's. Another point, if the medicine prescribed accomplishes the good intended, all is well; but if otherwise the druggist is not blamed, and he may even criticise the doctor's treatment. To dispense one's own drugs makes it very easy to use proper care in regard to the purity of the drugs used, makes it impossible for the prescription to be repeated again and again except at the discretion of the doctor, and keeps the patient under the constant supervision of the medical attendant, a most important consideration for the interest of both patient and doctor. My practice is a village and country one, but did I practice in a city I would still dispense my own drugs, and if favored with a large practice I could richly afford to keep a dispensing clerk. Some might object to the expense of keeping and dispensing their own drugs, but these are comparatively small matters, for less than three hundred dollars will keep in stock all of the drugs needed in practice. The ordinary druggist always carries several hundred dollars worth of notions and patent medicines, which the practicing physician has no need nor use for whatever. As for myself I charge a profit of from 50 to 100 per cent. on all drugs dispensed, and the usual professional fee besides. I receive just as much for my professional services under this plan as before it was adopted, as well as a good profit on my drugs; and still the patient is a large gainer in the lessened cost of the drugs. Frequently it happens that a four-ounce prescription will cost me so little that practically I make no charge for it, and yet the druggist would charge from 25 cents to 75 cents, according to his greed for money.

A few words about druggists alone: they are too numerous, and doubtless feel compelled to charge high to "make both ends meet;" but too many in the business does not justify exorbitant charges "just the same." They overestimate their importance, and seem to forget that they could be dispensed with altogether, except the upper class or manufacturing pharmacists. Too often they neglect to maintain honorably the relation which exists between them and the prescribing doctor. I believe that an increasing number of doctors are dispensing their own materia medica, a practice that will prove beneficial to both doctors and the public, and tend directly to bind patient and doctor more closely together; for they will become better acquainted with each other, and more likely to coöperate heartily.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, November 23, 1887.

The President, J. SOLIS COHEN, M.D., in the chair.

DR. CHARLES B. PENROSE read a paper on

Eleven Consecutive Cases of Abdominal Section for Disease of the Uterine Appendages.

Abdominal section is at present such a common operation, and the diseases for which it is performed are so well recognized, that I shall not report these cases in detail; I shall simply tabulate them, consider them collectively, and call attention to any special point of interest which may have occurred in the history of any case.

These cases were operated upon during the year 1887. They all recovered, and are at present well and able to attend to their various duties.

In five of the cases in this table the appendages were removed on only one side. In one of these cases (Case II, pyosalpinx and cystic ovaries) I found it impossible to remove the left tube and ovary. They were firmly adherent in a knot on one side of the uterus, and the uterus was bound down in the hollow of the sacrum. In the other cases of the unilateral removal I intentionally left the appendages upon one side. With the exception of the case of dermoid cyst, the women were young and desirous of having children; and at the time of operation I could discover no sign of any pathological condition in either the tube or ovary. I am aware of the fact that in cases of tubal disease it is often unwise to perform a unilateral operation and to leave even an apparently healthy tube, as it, in many cases, becomes subsequently diseased from an infecting focus in the uterus.

Though sufficient length of time has not yet elapsed to come to any definite conclusion with regard to my cases, yet so far I have had no cause to regret having left the sound tubes; and in one case the patient has become pregnant since the operation.

A point of interest in connection with the first case (salpingitis and cirrhotic ovaries) is the length of time during which the patient was fed by the rectum. She began to vomit as she recovered from the influence of the ether; and she continued to vomit everything which was administered by the mouth

Case.	Age.	Married or single.	Disease.	Date of operation. (1887.)	Parts removed.	Complete closure of wound, or drainage.	Result.
I.	30	Married.	Salpingitis and cirrhotic ovaries.	Feb. 16,	Both tubes and ovaries.	No drainage	Recovery.
II.	24	"	Pyosalpinx and cystic ovaries.	Mar. 14,	Right tube and ovary.	" "	"
III.	32	"	Salpingitis, multilocular cyst of ovary.	April 8.	Left tube and ovary.	" "	"
IV.	26	"	Double pyosalpinx and ovarian abscess.	May 19,	Both tubes and ovaries.	Drainage	"
V.	37	"	Double pyosalpinx, ovarian abscess, abscess and hæmatocele.	May 25,	Both tubes and ovaries.	"	"
VI.	30	"	Salpingitis and blood cyst of ovary.	June 20,	Left tube and ovary.	No drainage	"
VII.	23	"	Salpingitis and abscess of ovary.	July 3,	Left tube and ovary.	" "	"
VIII.	33	"	Salpingitis, blood cyst of ovary, uterine fibroid.	July 13,	Both tubes and ovaries.	Drainage	"
IX.	22	"	Double pyosalpinx.	Aug. 9,	Both tubes and ovaries.	"	"
X.	43	"	Dermoid cyst of ovary.	Aug. 17,	Left tube and ovary.	"	"
XI.	22	"	Double pyosalpinx.	Oct. 23,	Both tubes and right ovary.	"	"

for thirty-six days after the operation. There was no apparent cause for this excessive vomiting. The operation was simple, and was not followed by any obvious symptoms of peritonitis. The rectal injections, by means of which this woman was nourished for over a month, consisted of pancreatized milk, eggs and whiskey. Two-thirds of a quart of milk, one egg and three ounces of whiskey were administered in four or five doses during the twenty-four hours. During this prolonged course of rectal feeding she lost many pounds in weight. No food at all was taken by the mouth; the very small quantities which were occasionally administered experimentally were always immediately rejected. When she finally became able to take food by the mouth it was necessary to give it in the form of twenty-drop doses of soup or beef-tea.

In the table I have made no distinction among the different forms of non-purulent inflammations of the Fallopian tubes. All thickened, enlarged, adherent tubes, which did not contain pus, I have put down as salpingitis.

In investigating the histories of the cases of pyosalpinx, it was difficult to determine with any certainty the origin of the trouble.

I could not in any case obtain a clear history of gonorrhœa; though in several I had reason to suspect it. In four of the five cases of pyosalpinx the patients attributed the origin of their disease to a miscarriage. In Case V. (double pyosalpinx, ovarian abscess, and hæmatocele) the active suffering dated from a violent fall upon the ice several years before the operation. The fall was followed by bleeding from the vagina, which lasted several days; and from that time until the time of operation she suffered with great pain

in the lower part of the abdomen, which rendered it difficult for her to walk erect, and with evening chills after any exertion during the day. It is probable that in this case the fall had caused the partial rupture of a previously distended tube.

In all the cases of pyosalpinx there was a history of repeated attacks of pelvic pain and inflammation, which often confined the patient to bed for several weeks.

In two of the cases of pyosalpinx there was also ovarian abscess. In these cases the abscess cavity in the tube communicated directly with the abscess cavity in the ovary, and the origin of the ovarian abscess was obvious. In Case VII. (salpingitis and abscess of ovary), however, there was no pus in the tube. The tube was enlarged, adherent, and its fimbriated extremity was closed; and it did not communicate with the cavity of the ovarian abscess. The ovarian abscess contained about half an ounce of pus and had a distinct pyogenic membrane.

I think that abscess of the ovary is of more frequent occurrence than works upon gynecology admit. And though it probably is in general due to ovaritis caused by inflammation of the tube, yet it is not always associated with pyosalpinx.

In two cases of double pyosalpinx (Cases V. and IX.) a thin purulent fluid was found in the peritoneal cavity, and the intestines were found to be deeply congested when the abdomen was opened. The patients had probably been suffering for some time with general chronic peritonitis excited by the escape of pus from the distended tubes. The symptoms, however, before operation, had not pointed to general peritonitis, the patients having only complained of pelvic pain and in the back. The chance that such a con-

dition may occur in connection with pyosalpinx is a strong argument in favor of removing these abscesses by abdominal section, instead of evacuating them by the vagina, as is so often done.

The danger of assuming any case of peritonitis in a woman to be idiopathic, without a thorough vaginal examination, is obvious. I have the report of a case which occurred recently, where the patient was treated for several weeks for idiopathic peritonitis, and an operation done a few hours before death revealed double pyosalpinx and a ruptured ovarian abscess.

In six of the cases reported, an abdominal drainage tube was used. The average time of convalescence in these cases was no longer than in the cases where a tube was not introduced; and the severity of the symptoms following the operation—the elevation of temperature, the rapidity of pulse, and the pain—were much less marked in the drainage tube cases than in the others. The absence of pain in the drainage tube cases is probably in part due to the fact that most of them were cases of pyosalpinx, where the tissues, which were ligated and cut, were so far degenerated that their sensibility was much diminished.

I think that the danger of abdominal hernia following the use of a drainage tube is exaggerated. In one of my cases there is now a small hernia, but it occurred above the position of the tube and was probably due to some error in introducing the sutures. In some thirty drainage tube cases which I have seen in the practice of Dr. Joseph Price, there has, as yet, been no hernia. It is probable that hernia is due more frequently to a long or high incision, and careless suturing, than to a drainage tube.

The average length of time before the glass drainage tube was removed in my cases was about five days; the shortest time was two days, and the longest eight days. In but one case did the discharge from the tube become purulent.

The use of a cotton rope to act as a capillary drain adds greatly to the value of the glass drainage tube. It prevents any fluid from remaining in the bottom of the tube, and it removes the deposits of fibrin from the perforations in the glass.

There are so many points of interest in connection with Case X. (dermoid cyst of the ovary), that I shall report it in detail.

The patient was forty-three years old. She had had three children and five miscarriages. She had first observed the tumor eighteen months before the operation. It rapidly in-

creased in size, and when removed it was about six inches in diameter. It had never been accompanied by pain. The rapid growth of this cyst and the late period of life at which it was first observed are, I believe, very unusual. The patient had also a much distended gall-bladder, and at the operation a calculus was felt obstructing the cystic duct. During the operation the dermoid cyst was ruptured, and the contents, consisting of very oily material and many fine hairs, escaped into the abdominal cavity, and were removed with great difficulty. It was only after thorough sponging and irrigation that the peritoneum was cleansed. A drainage tube was introduced.

The patient suffered from severe shock after the operation. For the first three days the temperature remained normal or slightly subnormal. The pulse was about 115. There was considerable abdominal distention and pain; there was not much discharge from the drainage tube. On the third day, large quantities of bloody serum began to flow from the drainage tube. At the same time the tympany and general abdominal pain became much increased. The temperature ranged between 97.5°–100.5°. The pulse was 130 to 140. The respirations were 40 or over. The tongue was coated, and there was constant hiccough and occasional vomiting. The bowels had not been moved, and there was no escape of flatus.

An ounce of sulphate of magnesia was administered daily, for several days, and many turpentine enemata were given. The enemata were retained for a few minutes, and when they were rejected a large quantity of flatus escaped. The bowels were not moved, and there was no escape of flatus at any other time. As the abdominal distention and pressure increased, large external hemorrhoids, which looked almost like a prolapse of the rectum, appeared. On the fifth night a rectal tube was introduced, but it rendered but little service. Most relief was obtained from the turpentine enemata, and the patient frequently asked for them herself. The hiccough and vomiting ceased on the sixth day. The discharge from the drainage tube continued to be very profuse, though of lighter color. The abdominal distention, the pain and the hemorrhage were unchanged. On the seventh day after the operation, the suture at the upper angle of the abdominal wound was removed, and the nozzle of a long syringe was introduced among the intestines in order to determine whether there was any collection of fluid in the abdomen which was not carried off by the drainage tube. No fluid was found, and the wound was re-

closed. On the eighth day the bowels began to act. There was profuse watery diarrhoea for twenty-four hours, accompanied by the escape of large quantities of flatus. At the same time all the symptoms of peritonitis began to abate: the abdominal distention rapidly decreased: the discharge from the glass drainage tube became so slight that it was removed; the hemorrhoids began to diminish in size, and by the tenth day they had disappeared. The diarrhoea ceased in two days, without treatment: and three weeks after the operation the patient was able to leave her bed.

I have reported this case at length on account of the interesting phenomena attending the development and the subsidence of the peritonitis; and because it was treated throughout by sulphate of magnesia and rectal injections, and not by opium. And, in conclusion, I may say that it was not found necessary to use opium in any of the cases reported in this paper.

In the discussion which followed the reading of Dr. Penrose's paper,

DR. J. PRICE said: Dr. Penrose's report of his work affords an excellent opportunity to discuss pelvic surgery. While I have been greatly interested in every case reported and know the work to have been perfect from personal observation, I do not wish to discuss this report. I simply wish to speak of the present position of pelvic surgery, by whom, when, and where it should be done.

1st. By whom? I will read a quotation from McDowell:

"I think my description of the mode of operating, and of the anatomy of the facts concerned, clear enough to enable any good anatomist, possessing the judgment requisite for a surgeon, to operate with safety. I hope no operator of any other description may ever attempt it. It is my most ardent wish that this operation may remain to the mechanical surgeon forever incomprehensible."

Dr. Penrose is a trained surgeon; the ovariologist should be unsurpassed in surgical resource and ingenuity. Only skilful and trained hands should follow this calling. He should begin young. Many of the old-fashioned ovariologists were dangerous; they vaccinated babies until they were forty-five or fifty years old, and then began the study and practice of surgery in the abdominal cavity. Sad and sorrowful were the results; such is not the condition of affairs at present. The mortality now is almost *nil* in young and experienced hands, and in patients that are able to move about. The results now are very much better, even in that

class far advanced in the process of dying. Again, in a class of cases that the consider too dangerous to touch—I allude to all forms of pelvic inflammatory trouble—a class of cases presented this evening, affording examples of a state of professional ignorance and prejudice which is a disgrace alike to the enlightened time in which we live and to the enormous advances made by the art and science of surgery; we are far indeed in these cases from seeing the full application of these advances for the relief of suffering women. This operation saves life and relieves great suffering, restoring the patient to health and a life of usefulness. While one removes *diseased* ovaries and tubes, the indications present no difficulty. Nor can any one dispute the propriety of dealing with *pus* cases.

Secondly, as to the *time* of operation. Grave inflammatory troubles should be dealt with as soon as discovered; delay and repeated examinations are dangerous. We dread the delay of a day in *pus* cases. In conclusion, I will allude briefly to McDowell's work, by giving you a quotation from Dr. R. S. Sutton:

"In the light of all recent advances concerning the environs of an ovariectomy patient, I ask you to listen thoughtfully, and inquire of yourselves: Have modern operators had better environments than McDowell did? Is their quarantine better than his was? Whether accident or necessity or simplicity of border life provided these conditions so favorable to recovery, your orator will not inquire, but hopes to show that McDowell did operate under conditions as favorable as does Dr. Keith or Mr. Lawson Tait. 1. The patient was refused operation in her own home. 2. She was operated on in Dr. McDowell's own house. 3. History mentions but one assistant present at the operation. 4. The patient had never been tapped. 5. We may safely infer that the room in which the operation was performed contained, at this early date in Kentucky, no superabundance of furniture or upholstery. 6. That the room was ventilated by an open fire-place is more than probable. 7. The atmosphere was that of a healthy border town. 8. No sponges were introduced into the abdomen. 9. He ligated the pedicle and dropped it in. This operation will stand the criticism of the most exacting specialist of the year 1885 save in two particulars: viz., the ligature was not carbolized or scalded, the ends of it were left hanging out of the lower angle of the wound, and merely turning the woman on the side to permit all fluid to escape from the cavity of the abdomen was scarcely enough in that direction. Pause a moment! This k:

at the end of almost three-quarters of a century, the operation stands almost where McDowell left it, with one solitary exception, viz., the ends of the ligature surrounding the pedicle are cut short."

DR. J. M. BALDY said: In a recent number of the *Pittsburg Medical Review*, the editor, commenting upon a report of cases of abdominal section done at the Philadelphia Dispensary, states "that the fact that the operations were performed at the patient's homes with success, should do away with the old idea that the only place to do abdominal section is in a private hospital." The vast majority of operations at the Philadelphia Dispensary have been done at the patient's homes under conditions and surroundings which have been anything but desirable. If the immediate surroundings of the patient and wound are aseptic, the operation can be done with perfect safety anywhere.

In many cases of pyosalpinx, if a wealthy woman refuses to take the risk of the knife, she can by proper treatment be made comparatively comfortable without great risk of her life. However, the majority of cases of pyosalpinx, even among the wealthy, demand surgical interference sooner or later. If, on the other hand, the patient has to work for her living, and is suffering with recurring attacks of peritonitis, I think that in such cases the operation is called for always. The risks of the operation are comparatively slight. It can be performed by any general surgeon if he has a cool head and good surgical resources. The use of salines in the treatment of peritonitis is a point of extreme interest. From what I have seen of such cases there is no doubt in my own mind that the treatment by opium is a great mistake. Where there are the signs of beginning peritonitis, the use of large concentrated doses of salines rapidly relieves them. While the use of opium favors the occurrence of adhesions, salines would naturally tend to do away with trouble of that kind. Opium shuts up all avenues of escape for the product of inflammation and then tends to increase the trouble rather than to alleviate it.

DR. J. PRICE said: I am surprised at what Dr. Baldy has said with reference to pyosalpinx when he realizes how much trouble may come from a little pus. A case of pyosalpinx is always in danger. They suffer constant pain; they go down rapidly and die.

DR. J. C. DA COSTA said: I cannot agree with Dr. Price with reference to pyosalpinx. Others who have had a large experience when asked with reference to their method of treating this affection also differ from him. One

gentleman, with a large experience in the removal of ovarian tumors, has told me that he has seen many cases of pyosalpinx, but that they had all recovered without operation. My experience is much the same. Dr. Price says that it is never safe to allow the pus to remain. Let me state two cases. A woman had been suffering for fifteen years. The left Fallopian tube was as large as a small Bologna sausage. She was given the ordinary local and general treatment. One day a little bleb appeared on one side of the uterus. This was opened, and, on introducing the sound, it entered five and one-quarter inches. During the next few hours a large quantity of pus was discharged. This patient finally made a complete recovery. Another case: a young married woman, suffering with salpingitis, came under my care. The ovary was quite large. Ordinary common sense treatment with rest in bed caused great improvement. She began to go about too soon, and had a return of the trouble. At this time the ovary was as large as an orange, but in two months she had perfectly recovered. Would I in this case have been justified in removing the ovaries and thus destroying her hope of ever performing the duties which the Almighty sent her into the world to perform? In regard to the reports of cases cured by operation which we hear of, the question comes up as to their reliability. I grant that there is not the same mortality after abdominal section for salpingitis and other such troubles as there is after ovariectomy, but even if there is a mortality of even one per cent. the question arises, Is it proper to perform this operation when the patient can be relieved by ordinary treatment? There are in this city a number of hospitals that will take these cases and treat them and cure them, so poverty cannot be urged as a pretext. I believe that the gentlemen who make reports of their cases believe that the report is correct at the time that they make it. But I have had the opportunity of seeing a number of these cases some time after the operation has been performed, and the latter part of the history of the patient has not agreed with the published report. I will state two such cases in illustration. One was operated upon seven or eight years ago and was reported cured. She is still a nervous hysterical woman, who cannot sleep without an anodyne, and has a voice like a poll-parrot. In the second case the operation was done several years ago and reported as successful, but the patient was wretched and miserable until a year ago, when she fell into the hands of a quack who cured her.

Why do the reports and the results differ so? The women went to the surgeon in hope of relief, were told "the operation would cure them;" believed it, were operated on, and under the stimulus of hope felt as if they were cured, and that the pains they still felt were due to the operation and would pass away, and so were reported cured. After a while the old pains came back and they realized that they were not yet well, in spite of the operation and published cure. In a number of other cases of women reported well after operation, the least of their troubles was ventral hernia. In opening the abdomen, the operator is very apt to find what he is hunting for, and I have seen extirpated ovaries which were not diseased enough to demand it. It is not necessary always to remove both ovaries, as is often done in operating for ovarian tumors. I have left a second ovary as large as a lemon, and have had no bad results, as in a case operated on about two years ago. The woman has menstruated regularly since the operation and has had no trouble. The ovary has diminished decidedly in size.

DR. M. PRICE said: I would challenge some of the statements made by Dr. Da Costa. He says that salpingitis does not cause much trouble. I can show him a case which has been under medical treatment for five years. Two years ago an abscess burrowed down through the cellular tissue and discharged between the bowel and vagina. This case has been operated on five different times for fistula in ano, with entire removal of the recto-vaginal septum by operations, and until four weeks ago it had not been suspected that it was a case of pyosalpinx. These cases cannot be cured by simple medical treatment. There is no single case, that I have seen operated on, which stood one chance in fifty of living six months if the operation was not done.

DR. W. H. PARISH said: I have no doubt that those who advocate this operation will agree that not all cases of disease of the appendages demand operation. August Martin has said that three-fourths of the cases of disease of the tubes and ovaries do not require operation. There are also cases of gonorrhœal affections of the tube which do not demand the operation. I have seen one case where the inflammation of the tubes followed the occurrence of gonorrhœal inflammation of the vagina, and in which the trouble subsided; the woman subsequently became pregnant. With reference to the removal of ovaries and tubes that contain pus, I may say that we all know that these cases may continue

for years, but suffering from repeated exacerbations of inflammation. These patients are always in danger from the thinning of the tubal or ovarian wall, with the escape of pus, and the occurrence of general peritonitis. If we look over the records of any hospital or board of health, I think that we shall now find few deaths compared with the past, recorded as due to pelvic abscess and general peritonitis. I think that many cases of pelvic abscess and of general peritonitis have been in their origin cases of pyosalpinx. I am strongly in favor of the removal of tubes and ovaries where there is pus. While a patient may enjoy a certain amount of comfort with pus in the tubes, yet she will be liable to frequent exacerbations, and may have her life placed in great danger at any moment. I am sure that the operation for the removal of tubes and ovaries in pyosalpinx or ovarian abscess has come to stay, no matter what the future position of the operation for other conditions may be. I think that those who urge the treatment of these cases without operation are doing great injustice to a considerable number of patients, and also no little injustice to the surgery of to-day. My own experience with the operation warrants my endorsement of it.

DR. C. B. PENROSE said: I have only to say, in conclusion, that such tubes as I have shown are useless and dangerous to the woman. They could not permit the passage of spermatozoa or ova. I cannot agree with Dr. Da Costa's statement about abscess of lung or brain. I think it is proper to open an abscess wherever it occurs, and not to trust to nature; and when possible to make a complete removal not only of the pus but of the abscess walls, as we do in pyosalpinx. In cases of pyosalpinx said to have been cured by medical treatment, there is always an element of doubt with regard to the diagnosis. Such cases may sometimes occur. But there are few physicians skillful enough to make a positive diagnosis of pyosalpinx before the abdomen is opened. All of the cases on which I operated had had several months or years of treatment in the hospitals before the operation was performed.

DR. EDWARD JACKSON read a paper on

"Gleditschine,"

in which he said that analysis and tests have pretty well disposed of this alleged new local anæsthetic and mydriatic; and gleditschine has lost its interest for the ophthalmic surgeon. But one incident, disagreeable as its ending may have been to some of us, is not without its useful lessons:

First.—It is shown that such a fraud cannot be carried far even with a drug as difficult of positive chemical identification as cocaine. And every such attempt at fraud can only make more brief the period, and decrease the profit, of succeeding attempts.

Second.—It has been demonstrated that cocaine can produce anæsthesia through the unbroken skin; although, as I have pointed out, this is extremely superficial; and "to make a painless incision in tissues anæsthetized in this way, one must do it by repeated superficial cuts with the knife, keeping all the time the cut surface bathed with the solution."

Third.—Attention has been drawn to the *Gleditschia triacanthos*, and the genuine *Gleditschia* discovered and studied nine years ago by Dr. Lautenbach, but recently in a fair way to be forgotten. In the direction of a further study of this substance lies the probable path of profitable future investigation. The leaves have been proven practically inert, and for several months it may be impossible to obtain specimens of the unripe fruit. But other parts of the plant might be tested for it. In the *Medical Age* of November 10, Dr. Crull states that he has cured gleet with a decoction of the bark of the root of the thorny honey locust (the more common variety), and that taking a tablespoonful of the decoction himself "caused nausea, giddiness, dimness of sight, cold perspiration, and a prickly or smarting sensation of the tongue and throat. The symptoms continued for nearly three hours, when they gradually abated. The evacuation of the bowels the following morning was very bilious and watery."

Exhibition of Instruments.

DR. J. PACKARD exhibited a case in which were conveniently arranged the various articles required in the application of antiseptic dressings.

DR. J. M. BALDY presented a

Fibroid Tumor with a Fibroid Uterus.

The patient from whom the tumor was removed was a woman between the age of forty and forty-five years. She had carried the tumor for a number of years, and had gotten along comfortably until last spring, when she says that she suddenly felt something slip back in the abdomen. After that she had pains in the legs, and the abdomen began to swell. The legs also became cedematous. She was tapped in July, and since then has been tapped eight times by her physicians. The operation was repeated, toward the last, every ten days. I performed

abdominal section one week after the last tapping, and at the time three gallons of fluid escaped. The urine contained pus and a certain amount of albumin, but no tube casts. The heart was in good condition; the general health failing rapidly. The ascites was attributed to the pressure of the tumor.

The operation was performed thirteen days ago. The tumor was first removed by enucleation from the fundus of the uterus; then, the broad ligaments having retracted, a Kœberle nœud was thrown around the uterus at about the internal os. The pedicle was treated by the extra-peritoneal method. A glass drainage tube was introduced. The peritoneum was found to be enormously thickened. Since the operation a large quantity of serum has escaped through the tube, over one quart a day. The patient had an acute attack of local peritonitis resulting from pressing with both hands on the tube when coughing. She was treated with salines, and the peritonitis rapidly disappeared. At the same time the discharge from the tube was abruptly discontinued, having dropped in eight hours from three half-pints to as many drachms, and has so continued for the last two days.

The points of interest in the case are: the woman's age,—although near the menopause, she could not have possibly lived long enough to hope for any relief in this direction; the large amount of serum discharged from the drainage-tube, and its sudden stoppage; the possibility of carrying so large a tumor for years and only suddenly beginning to suffer from it; the enormously thickened peritoneum. The case well illustrates the folly of repeated tapplings.

DR. H. A. SLOCUM exhibited a specimen of

Placenta Prævia in Situ.

The patient was pregnant for the thirteenth time. After meeting with a fall, she suffered with frequent profuse hemorrhages of short duration. The bleeding occurred at irregular intervals, and there was no complaint of pain. When seen, on the occasion of the last hemorrhage, a tampon was applied, as the patient was so weak that it was not thought advisable to accomplish immediate delivery. The patient, however, did not rally, but died from exhaustion twelve hours later.

—According to C. E. Dodsley (*British and Colonial Druggist*), oil of sassafras is the best deodorant for iodoform, 4 drops sufficing for an ounce of the iodoform.

MEDICAL SOCIETY OF THE COUNTY
OF NEW YORK.

Stated Meeting, November 28, 1887.

The President, LAURENCE JOHNSON, M.D.,
in the chair.

**Malignant Tumor in an Umbilical Hernial
Sac—Remarks on the Etiology of Cancer.**

DR. DANIEL LEWIS gave the history of the case. The patient was a woman, sixty-seven years old, who fifteen years ago developed a hernia while lifting her mother. It had caused her no trouble, and she had done nothing for it. It was readily reducible in the recumbent posture until a year ago, when she began to suffer pain, and the tumor became more difficult to reduce. When Dr. Lewis saw her, in February last, she had become emaciated, had some fever, was sleepless, and pain radiated from the tumor to the pelvis. She had never borne children. Examination showed a tumor surrounding the hernial sac. An operation was consented to. The sac was found free of intestine, and it contained some omentum which was not diseased. The wound was closed as after an ovariectomy. The woman rallied, but died the third day, apparently of shock.

Dr. George T. Elliot made the microscopical examination. It was not difficult to determine the nature of the growth, as portions of the sections were found to be composed of small spindle-shaped cells, with here and there a few large round cells. While in others the latter were arranged in more or less large alveoli, formed by the bundles of connective tissue; in many of these alveoli capillary blood-vessels, which were abundant throughout the tissue, penetrated between the cells contained in them. From these features it was evident that the new growth was a sarcoma, composed of mixed cells, spindle-shaped and round.

In addition to the sarcomatous tissue, there were other histological elements which contribute greatly to the interest of the specimen. Distributed throughout the specimen more or less glandular tissue was found, in every way identical with the glands of Lieberkühn. The presence of intestinal glandular tissue in this tumor is not an extraordinary fact, but yet one which is very rarely met with. Growths of this class occur at the umbilicus, and are known under the name entero-terotoma. Dr. Lewis regarded the case as presenting further evidence of the fact that a disease, in

the beginning non-malignant may, and often does, prove to be the exciting cause of cancer. He did not attach much importance to the view that the disease was hereditary.

DR. ROBERT T. MORRIS read a paper entitled

A Few Practical Remarks About Bunions.

It treated of the compressing effect of the shoe and the reflex action thus excited in the tendons as causes of the deformity. In the treatment the shoe should be made broad, nearly straight on the inner side; there should be a separate compartment formed by a strip of leather sewed into the welt of the shoe to retain the great toe in normal line. If necessary, the ligament should be cut, or the head of the metatarsal bone excised, and a retaining splint be worn during the healing process, and the compartment shoe subsequently.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 1, 1887.

The President, A. JACOBI, M.D., in the chair.

**The Foot and Mouth Disease as it Affects
Man and Animals, and its Relation to Human
Scarlatina as a Prophylactic.**

DR. JOHN W. STICKLER, of Orange, New Jersey, in this paper gave his views, based on observation and experiments, of the possibility of preventing scarlatina by inoculations with the virus of the foot and mouth disease in animals, or of a disease produced in animals by inoculations with the scarlatina virus of man. In the course of his remarks, the author referred to the epidemic at Hendlen, England, and attributed the outbreak of scarlet fever there to the disease in the cows from which the milk supply came. The affection from which those cows were suffering corresponded to a disease which had followed exposure of lower animals (the cow, etc.) to the contagion of scarlet fever in man. The symptoms in the two cases were described. Among his other experiments was the inoculation of children with the virus obtained from supposed foot and mouth disease in cattle and subsequent exposure to scarlet fever without contracting the disease. The cases were three in number. In trying to develop scarlatina in the lower animals by inoculating with the virus obtained from scarlatina in man, he had experimented on colts, dogs, cats, and the cow. Among the symptoms resulting from such inoculations were sore

throat, redness of the mucous membrane of the mouth and nose, elevation of the temperature above 101° F., desquamation of the cuticle. It seemed a fair inference, he said, that the disease was scarlet fever. Could we use this virus in such a way as to prevent the development of scarlet fever in human beings? Two children inoculated with it, and afterward exposed to scarlet fever contagion, escaped the latter disease.

The discussion which followed was participated in by Drs. A. H. Smith, McLean, Sr., McLean, Jr., Stubbard, J. Lewis Smith, J. C. Peters, Professor Law, of Cornell University, and the author. Drs. McLean and Professor Law, interested in veterinary surgery, said that foot and mouth disease was common in England and very rare in this country. One attack in the bovine race did not afford immunity from future attacks. The so-called scarlet fever in horses and cattle was not contagious, and in no way resembled scarlet fever in man. Dr. McLean, Jr., said veterinarians did not acknowledge that the outbreak of scarlet fever at Hendlen, England, was due to the disease in the cows supplying the milk. Granting that it came from the milk, it might have been from water with which the milk was diluted, or from the cans exposed to the contagion of scarlet fever. Foot and mouth disease, in his opinion, had visited this country but twice. Professor Law was a great admirer of Pasteur, but he believed that gentleman had done much to spread anthrax and hydrophobia by sending out the virus for experimental purposes; and he thought experiments with the virus of the foot and mouth disease should be confined to Europe where the disease was prevalent.

REPORTS OF CLINICS.

BELLEVUE HOSPITAL, NEW YORK.

GYNECOLOGICAL CLINIC—PROF. POLK.

Inflammation of the Bladder in a Woman; Cystotomy.

On Nov. 14, 1887, Prof. Polk showed the class a woman who had suffered with inflammation of the bladder and marked irritability for five years. In commenting on the case, Prof. Polk remarked that a good deal of induction is met with in this affection, especially when it is of long standing, and the mucous membrane has a tendency to throw itself into folds. This is an invariable accompaniment of long-continued inflammation of the bladder. The causes of this condition are various: it

may be dependent upon a congestive and thickened, or morbidly sensitive state of the mucous membrane of the bladder, and also of the urethra; it may be a hysterical affection, or depend upon a prolapse of the anterior wall of the vagina; or, again, it may be due to a morbid state of the urine. He incidentally mentioned the case of a young woman who was compelled to hold her water all day, and in consequence developed a cystitis. More women are afflicted with slight cystitis than one would believe. In such cases, the inclination to pass water may occur only during waking hours, the patients passing comfortable nights. This patient, however, is obliged to pass her water even during her sleeping hours. Her condition has become unbearable to her, and she comes here for relief.

This affection is very difficult of treatment. The plan usually adopted consists in washing out the bladder, and the application of irritants, such as nitrate of silver, etc. Remedies of different kinds have been tried in this patient, but without effect, so that to-day I propose to perform cystotomy. In this operation, the patient is placed in the lithotomy position, and an incision is made into the base of the bladder, through the trigonum, large enough to introduce the index finger, in order to make a thorough examination of the interior; a drainage tube is then introduced. In a week or ten days the patient will have recovered.

SURGICAL CLINIC.—PROF. DENNIS.

Fistula in Ano.

In opening his lecture, Nov. 15, 1887, Prof. Dennis said: To-day I shall bring before you several cases of fistula in ano, show you their various forms, and illustrate their mode of operation; and, time permitting, also some other cases with which you are likely to meet. *Fistulae* in ano are of three kinds: First, the complete; second, the blind external; and, third, the blind internal; but *all* have their seat in the ischio-rectal fossa. The complete fistula, the most common form, communicates with the gut internally by means of a sinus. The external opening being, as a rule, near the margin of the anus, and the internal usually just above the sphincter; the fistula, however, runs higher up and forms a *cul-de-sac*. The blind external fistula, so-called from its having only an external perforation, and no internal opening, does not communicate with the rectum at all. The blind internal fistula is so called from its having an inner perforation

but no external opening. The two latter forms are known also as the incomplete fistula.

Fistulæ are mostly due to some mechanical irritation in the gut, such as fish-bones, pins, etc. They may result from traumatism; and sitting upon cold and wet stones has given rise to this affection. Fistula is often found in connection with phthisis, and it has been thought by some observers advisable to allow such a fistula to continue, believing that its drainage would ward off the lung trouble. But experience has shown that it is better to operate upon them.

The operation for *complete* fistula is simple: A grooved director is passed through the fistula into the bowel, and the latter is slit open. The sinus is then thoroughly scraped out with a Volkmann's scoop, otherwise a return of the fistula may be expected. The wound is then well packed, and dressed with iodoform gauze, which is kept in position by means of a T bandage. It is necessary to thoroughly purge the patient the night before, to give an enema on the morning of the operation, and to etherize completely, as the anus and rectum are the last parts to come under the influence of the anæsthetic. The treatment after the operation consists in arresting peristaltic action of the bowels by means of opiates; in giving milk diet, and in securing rest for a week or ten days.

The proceeding in the cases of blind external and blind internal fistulæ is first to convert them into complete fistulæ, and then to operate as for the latter disease.

Ischio-rectal Abscess.

Besides fistulæ, we have in this region a troublesome affection called the ischio-rectal abscess. You at once notice the difference in appearance between the cases of fistulæ which I have just shown you, and these, in which pus has formed around the rectum, in the adipose tissue of the ischio-rectal fossa. The treatment in these cases consists in making an incision along the anus, scraping out well all the pyogenic tissue, and then packing and dressing as in the cases of fistulæ.

Prolapsus Ani.

Another affection you may probably frequently meet with in children is *prolapsus ani*, which is a protrusion of the mucous membrane of the rectum, due to simple relaxation of the tissues, which occurs usually in feeble children. The prevention of the prolapse may frequently be brought about by allowing the child to defecate in the horizontal position. Another method of treatment consists in giving them injections, and after defecation a suppository of cacao-

butter and iron. Obstinate cases may require the excision of a triangular piece of the bowel.

MEDICAL CLINIC.—PROF. LOOMIS.

Enlargement of the Liver.

The first case shown to the class by Prof. Loomis, Nov. 15, 1887, was a man who had been operated upon a number of times for a stricture of the urethra, which still existed. He was admitted to the hospital in May of this year, and again in September. No enlargement of the abdomen was noticed upon his first admission. The symptoms present were: pain on the right side, with enlargement in the epigastric region; dullness on percussion, which extended downwards to a line drawn across the abdomen immediately above the umbilicus. Great tenderness upon pressure is present. The edges of the liver are round, but uneven. The surface of the liver feels rough and uneven, and gives no sense of fluctuation. The temperature has all along been normal, except on the 9th inst., when it rose more or less suddenly to $101\frac{1}{2}^{\circ}$ F., and then gradually fell to normal, which it is to-day. Vomiting and jaundice are wanting. "In cancer of this organ jaundice is generally not present, unless the glands in the portal fissure press against the bile-duct, or the bile-duct is compressed by a cancerous nodule." The patient had been aspirated, but, from the examination of the fluid collected, it was impossible to determine whether it was an abscess, cyst, or sarcomatous growth. Under observation, the enlargement had progressively increased in size. The patient has a pinched expression of countenance, is anæmic, and greatly emaciated. An explorative needle has also been passed into his liver, and the examination showed the absence of cancer cells. Prof. Loomis thought that that proved nothing, and did not exclude the possibility of its being of a cancerous nature, as it was possible to penetrate healthy liver between the cancer cells.

"In diseases of this organ we classify painful and painless enlargements. Abscess and cancer are among the painful enlargements; perihepatitis is also accompanied by pain. Fatty and waxy liver and hydatids are among the painless enlargements. Again, we have smooth and uneven enlargements of this organ. Among the former may be mentioned fatty and waxy liver. Hypertrophic cirrhosis is generally uneven. Abscess is bulging, but may be smooth at one point and bulging at another. Hydatid disease is bulging, but accompanied by no pain."

"In this case we have pain and enlargement,—a progressive enlargement, an enlargement presenting a rough and uneven feel, with round but uneven edges; there was no vomiting, no jaundice, and the temperature has been, with perhaps a day's exception, normal throughout. What is the matter with him?"

Five of the six students pronounced the disease cancer of the liver, and the sixth hypertrophic cirrhosis. Prof. Loomis said, *if it is not hypertrophic cirrhosis, it is cancer.*

[A week later the patient was failing, and the case looked more and more as if it were one of cancer.]

The second Case was one of *pneumonia* secondary to a *pleurisy*. This patient, a peddler, did not feel quite well on the 8th inst., but went to work as usual. During that day he complained of pain in the head, in his right side, and in his bones, and went

home, feeling badly. Next morning the pain in his side increased and he felt weak. He has had no chill or chilly sensations, and coughing was impossible on account of the pain. He then had no expectoration. The patient was admitted into the hospital on the 10th with fever, a slight hacking cough, and "raised" something. Temperature 103° F. on that day; went down to 101° F. in the morning, and up again to 102° F. in the evening on the 11th; and steadily fell from that time. He had bronchial respiration when first examined, and now presents increased vocal fremitus, dullness, bronchovesicular respiration and crepitation. There is no albuminuria, no cardiac trouble.

"Pleurisy, as a rule, occurs upon the *left* side of the chest. A pleurisy of the *right* side is generally secondary. This patient has had an extensive pleurisy, and now has a pneumonia."

EDITORIAL DEPARTMENT.

PERISCOPE.

Disease of the Nose as a Cause of Inability to Fix the Attention Upon a Special Object.

M. Guye, of Amsterdam, in a paper read before the 60th Congress of German Naturalists and Physicians, in September, 1887, spoke of the inability which some persons with an affection of the nose experience in fixing the attention upon a special object. For this condition he suggests the name *aprosesia*, which means "an inability to fix" the attention. From the *Deutsche med. Wochenschr.*, October 27, 1887, the following account of his paper has been taken: After saying that this affection had been overlooked or barely mentioned among the other causes of cerebral disturbance of reflex origin, he reported the three following cases, which illustrate the disease:

In the first case, M. Guye had one child of a man under treatment at his clinic for chronic catarrh of the nose, and was asked to see another child whose nose was so stopped up that he could not breathe through it, and who seemed to be incapable of learning anything whatever: he had been to school a year, but had not yet been successful in memorizing the letters of the alphabet. An examination disclosed the fact that the nasal fossæ were absolutely impermeable, as the result of exuberent adenoid vegetations. These were broken down and partially cut away. A

week later, the father returned to inform M. Guye that in the interval since the operation his boy had been to school and had acquired the whole of the alphabet.

In the second case, a man twenty years of age was sent to M. Guye by Professor Stokvis in June, 1885, who had been subject since his twelfth year to slight ringing in the ears, which ordinarily developed in the morning, and ceased gradually in the course of the day. Since March the patient had noticed each evening a great inaptitude for intellectual work, and at the same time a sensation of vertigo. Six weeks of complete rest for the mind, combined with the internal use of iron, effected no improvement; every time he tried to work, he was seized with vertigo and headache. It was entirely impossible for him to retain anything he read. An examination disclosed the fact that the patient had chronic nasal catarrh, that he was accustomed to breathe with his mouth open, and that the inferior turbinated bone was swollen, and the pharyngeal tonsil hypertrophied. M. Guye cut away the larger part of the pharyngeal tonsil, employed injections into the nasal fossæ, and applied an apparatus to compel the patient to breathe through his nose. The patient returned on June 22, to report decided improvement. He had no relapse. The inferior turbinated bones were subsequently cauterized, and the patient passed his examination in the following September, and has pursued his studies at the University.

The third case was that of a student of medicine, twenty-three years old, in which the symptoms very much resembled those given in the second case, while the local conditions were substantially the same as in the first case. There was, however, in addition a serous effusion into the tympanic cavity of each side, which, strange to say, gave rise to no ringing in the ears nor difficulty of hearing. The treatment consisted in ablation of the adenoid tumors of the nose, and inflation of the middle ear cavities. Subsequently, the effusion into the cavity of the middle ear was removed by tapping, and the cavity washed out. The membrane soon healed, and in about two months the cerebral functions of the patient had become normal.

The author refers the primary cause of this affection to an obstruction to the elimination of products formed in the brain which cannot be assimilated, and in this connection mentions the researches of Axel Key and of Retzius, which show that the lymphatic spaces under the dura mater are in communication with the mucous membrane of the nasal fossæ. He then seeks to prove that the mental exhaustion which occurs in pupils is often rendered easy by the existence of an affection of the nose, which acts as a predisposing cause. An instance in which *aproxexia* developed under the combined influence of mental overwork and an affection of the nose was cited as occurring in a boy of sixteen, who had been successfully treated at the age of seven for difficulty of hearing and chronic nasal catarrh with adenoid tumors. This patient also recovered.

Hemorrhage After Excision of the Tonsils.

Linhard and Luschka have already, from anatomical considerations, spoken against the generally prevalent fear of wounding the internal carotid artery in tonsillotomy. Hyrtl's and Rüdinger's statements do not agree with those of Linhard and Luschka. O. Zuckerkandl (*Wiener med. Jahrb.*, 1887, Heft 6), by investigating the anatomy of the part, has found that it is impossible to wound the internal carotid artery in this operation, as, apart from the wall of the pharynx and the fat which occupies the region behind the tonsil, there is in addition a muscular layer, which lies in front of the internal carotid artery. In a review of Zuckerkandl's paper, in the *Centralblatt f. d. med. Wissensch.*, October 29, 1887, it is further learned that there is just as little risk of striking the artery in scarifying the tonsil, or in opening an abscess in it. On the other hand, an

injury would be conceivable in opening a retro-pharyngeal abscess.

Hemorrhages are rather to be explained by the behavior of the arteries which penetrate into the tonsil. Either the vessel works its way through the fibrous wall of the tonsil and pierces the tissue proper, or it lies on the capsule, and only enters the tonsil after forming several loops and coils. If now the artery is cut obliquely, it withdraws into the tissue, and the hemorrhage stops spontaneously. But if the incision is in the plane of the posterior capsule of the tonsil, spontaneous stoppage of the bleeding is impossible, as the intimate connection between the wall of the vessel and the capsule of the tonsil prevents a narrowing of the lumen of the vessel. Therefore, the surgeon must avoid letting the incision of amputation fall in the plane of the lateral wall of the tonsil, and he can best do this by simply chipping off its swollen top.

The only artery which can be tied with propriety is the external carotid, as only the branches of this can be wounded. In most cases, however, compression against the lower jaw by means of Pean's forceps will be sufficient to stop the hemorrhage.

Laparotomy for Chronic Peritonitis; Injection of Iodine; Cure.

Dr. Dittmer, of Berlin, reports a case of this kind in the *Berliner klin. Wochenschrift*, October 31, 1887, of which the following is an abstract:

Martha B., eight years old, was taken sick on July 7, 1879, with symptoms of acute gastro-enteritis. After eight days she presented a picture of typhoid fever, without the eruption, and with slight, if any, enlargement of the spleen. During the second week, the swelling of the abdomen steadily increased, and the tenderness extended all over the belly, so that beginning tubercular peritonitis was suspected. The fever was uniformly remitting, the diarrhoea persisted, and the child grew frightfully thin. Four weeks from the beginning of the attack, an effusion of fluid could be made out for the first time. At this time, too, the patient improved in all respects except the effusion. On August 29, there was an aggravation of all the previous symptoms, and the development of two points at which perforation of the abdominal wall was threatening. One of these points was in the right hypochondrium, about one finger's breadth below the margin of the ribs, in the mamillary line; the other was at the navel, and neither was larger in size than a penny. As the first spot grew larger during the next few

days, and the fever assumed a hectic type, an incision was made on September 2, and twelve pints and a half (6 litres) of laudable pus evacuated. A drainage tube was inserted, the wound dressed with salicylated cotton, and the cavity washed out daily with a solution of permanganate of potash. Recovery was so satisfactory that the drainage tube was removed toward the close of October; the patient having been out for the first time on October 9. But about the middle of November, a relapse occurred, and pus was discharged spontaneously through an opening at the navel, where perforation had threatened at first, in spite of the fact that the original opening continued patulous. Pus was discharged through both wounds; fluids injected into one opening returned through the other. The perforation at the navel closed by New Year's, but the other opening persisted, and from it a little thin pus continued to be discharged. Finally, on March 8, 1880, tincture of iodine was injected into the fistulous track, and repeated on March 12, 19, 27 and April 11. The iodine was well borne, and recovery was complete on April 15, 1880. The author states that he has subsequently seen the patient frequently, and that she has developed in a girl with blooming health.

A Case of Abscess of the Spleen.—Operation; Cure.

In the *British Med. Journal*, November 12, 1887, Mr. Chowdhury, Assistant Surgeon to the Burdwan Municipal Hospital, India, reports a case of abscess of the spleen with the following history: A man, about forty years old, had been suffering for some months with an undefined swelling in the splenic region. He also complained of some pain in the part, and had had occasional fever. He began to expectorate blood, and some purulent-looking matter, though previously he had had no lung complaint. From the fact that the spleen was enlarged, and that there was moist crepitation in the left lung, extending from the lower to the upper part, the sputum being chiefly composed of blood and pus, it was concluded that an abscess of the spleen had formed and burst into the left lung. Another symptom leading to the same diagnosis was that he was not much troubled with the night and morning cough so common in patients with bronchitis and phthisis. Subsequently, the abscess was seen pointing in the splenic region, and on September 17, 1886, it was opened by a free incision. About ten ounces of pus came out at first, followed by *æbris* of splenic tissue

mixed with blood and pus. A drainage tube was inserted, and the part dressed with boracic lint and iodoform. On September 26, he was discharged cured.

The author states that he has practiced in the malarious district of Burdwan (Bengal) for more than eight years, and has personally treated over 30,000 cases of malarious fever, but out of the whole number has only met two cases of abscess of the spleen, in addition to the one just described.

Oxygen in Puerperal Eclampsia.

A. Bompiani reports, in the *Osservatore*, September 25, 1887, two cases of eclampsia with albuminuria, occurring during pregnancy and during confinement, in both of which he employed oxygen. In the first case, which was proceeding to a fatal termination, he endeavored by the use of oxygen to obviate the asphyxia, which transiently developed, and was dependent upon the condition of the lung; while in the second case, which survived, oxygen was employed as a last resource, and effected the disappearance of the anasarca, as well as of the convulsions.

The first patient was a young woman twenty-seven years old, who, at the end of pregnancy, was seized with convulsions, which occurred every fifteen minutes. Bromide of potash, chloral hydrate, leeches, warm vaginal douches, subcutaneous injections of morphine were without effect, and coma and asphyxia were strongly developed. Inhalations of oxygen produced slight improvement; the child was delivered by forceps; but the patient died after nine inhalations.

The second patient was a young woman at the end of pregnancy, who was seized with violent convulsions. A living child was delivered by the forceps; but, after delivery, fresh paroxysms developed, against which inhalations of oxygen and injections of ether were successfully employed.—*Deutsche Medizinisch-Zeitung*, Oct. 20, 1887.

Poisoning with Chlorate of Potash.

Dr. George T. Welch reports in the *Transactions of the Medical Society of New Jersey*, for 1887, a case of poisoning with chlorate of potash. The subject was a woman, 28 years old, who took at one draught four fluid ounces of a saturated solution of this salt. She had great prostration, straining, vomiting, and frequent micturition. Her stomach was emptied with an emetic, and nerve stimulants and opium were administered. The next day she was quite recovered.

Med. & Surg. Report

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium,	6.00
Physician's Daily Pocket Record,	1.25
Reporter and Pocket Record,	6.00
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets,

P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 10,250 copies.

BACTERIOTHERAPY IN SPLENIC FEVER.

In this age, when the tendency is to refer the causation of all general diseases to micro-organisms, it is comforting to hear anything which may be said in their defence. In *Virchow's Archiv*, Bd. cviii, Heft. 3, Dr. A. D. Pawlowsky has published a contribution to the study of "bacteriotherapy," in which he states that he has finally concluded, after a long series of experiments, that it is possible to cure splenic fever by means of bacteria. Splenic fever, anthrax, charbon, malignant pustule, or bloody murrain, as the disease is variously called, is an acute infectious disease, affecting herbivora and omnivora for the most part, but communicable to other mammals, including man. The specific cause of the disease has been proved to be the bacillus of anthrax, or its spores. Inoculations as a prophylactic against anthrax were first instituted by Burdon Sanderson and others in 1878. The results obtained by these experimenters were very successful. Other methods have since been tried, but

probably that of Toussaint is as simple and effective as any. The latter consists in heating the virus for one hour, at a temperature of 131° F., so as to diminish its activity, and then inoculating the animals to be protected. Pawlowsky, however, seems to have developed some new points in his experiments. From a review of his paper in the *Deutsche Medizinal-Zeitung*, November 14, 1887, we learn that cure of the local anthrax can be obtained by means of a series of subcutaneous injections of different micro-organisms, at the points at which the disease originates, or in the neighborhood of these. The most powerful antagonist to the anthrax bacillus was found to be Friedländer's diplococcus of fibrinous pneumonia. This, at least, is the inference which Pawlowsky draws from the fact that all of the eight rabbits suffering with anthrax, which were injected with it, recovered. The staphylococcus aureus stands next in efficiency to the diplococcus of pneumonia; as four rabbits, which were treated with it by hypodermic injections, recovered. It is somewhat surprising to learn that even non-pathogenic organisms are capable of curing local anthrax. This the author declares to be the fact, and places the bacillus prodigiosus third in effectiveness. In the case of this bacillus, a single hypodermic injection was not successful, but a second resulted in cure. Of ten rabbits which recovered from anthrax after treatment with the bacillus prodigiosus, eight had subcutaneous suppuration at the spots into which this bacillus had been injected. Finally, the fourth place as a remedial agent against the anthrax bacillus is accorded by the author to the streptococcus of erysipelas. Of seven rabbits treated with it, only two died.

Coming now to the treatment of general splenic fever with intravenous injections, it was found that proportionately favorable results were obtained only when anthrax bacilli were injected simultaneously with the diplococci of pneumonia. Of seven rabbits treated in this way, two recovered, three died of embolism, and two of anthrax. If the injection of anthrax bacilli was followed by that of the diplococci, instead of both

being given at the same time, the results were not as favorable. This is clear from the fact that of five rabbits which were so treated not a single one recovered. It is important to note, however, that instead of dying as animals unprotected from anthrax generally do, in from thirty-six to forty hours, the rabbits in question survived from seven to fourteen days; showing that the injections had enabled the organism to maintain the struggle against the disease for a longer time. Intravenous injections of the staphylococcus aureus did not save the animals from anthrax; while injections of the streptococcus of erysipelas and the bacillus prodigiosus lengthened the struggle of the animal against anthrax to from three to five days.

**OPERATIVE TREATMENT OF INTERNAL
OBSTRUCTION OF THE BOWELS.**

The treatment of persistent obstruction of the bowels, dependent upon some intra-abdominal condition, is one of the most interesting questions in medicine or surgery. There are able and conscientious surgeons who think the tendency at the present time is too much toward early operative interference. Prof. John Ashhurst, of this city, for example, and Prof. Madelung, of Rostock, have presented strong reasons for prudence in proceeding to operation. On the other hand, the comparative safety with which the peritoneal cavity may be opened, in these days, has induced other surgeons to protest that many patients lose their lives because they are not given the chances of an operation.

At the last Congress of German Surgeons, there was an active discussion of this subject, and the general opinion was favorable to operation in cases which do not readily yield to medicinal treatment, and in which there is a strong presumption of a mechanical condition not amenable to medicinal measures.

As to the operation to be chosen, the majority of those who spoke favored the formation of an artificial anus. But KUMMELL, of Hamburg, in the *Centralblatt für Chirurgie*, Nov. 5, 1887, opposes this opinion, and

gives the reasons which incline him to choose laparotomy as the operation best suited for internal obstruction of the bowels. In support of his views, he cites his own experience in ten cases, in seven of which he performed a laparotomy, and deplores the delay of medical men to submit their patients to surgeons until after they have exhausted all other means, and their patients are *in extremis*. He mentions a case in which he himself abstained from operation because he attributed his patient's trouble to tubercular peritonitis—for which he had good reason—and found at the autopsy that the symptoms of obstruction were due to a band compressing the upper part of the small intestine. The peritonitis which exists in many cases of obstruction, and which is sometimes regarded as its cause, he believes to be usually secondary to it. Taking everything into consideration, he pronounces strongly in favor of laparotomy when the circumstances justify an operation, and thinks this furnishes the best way to discover the exact nature of the obstruction and the best means of overcoming it. To make an artificial anus is to lose the advantage of sight and touch in determining the condition on which the obstruction depends, and to do an operation sometimes ineffectual and often demanding another operation by no means free from danger.

The paper of Kummel, to which we have referred, is too long for us to do it justice here, but we cannot refrain from giving our readers the benefit of the author's suggestions in regard to a part of the operation of laparotomy, which is often very difficult, namely, the reposition of the intestines. Kummell's method of accomplishing this is to place a folded napkin or towel over the bowels, and to tuck its edges under the edges of the incision, upwards under the sternum, downwards into the pelvis, and on the sides under the abdominal wall. When this is done, and the whole is controlled by the hands of an assistant, he places the approximating sutures in position and has the towel withdrawn gradually as the sutures are tightened. In this way he says he has no difficulty in getting the bowels in place, and no need for

the dangerous procedure of puncturing them so as to empty them of gas. He mentions, also, with approval, the suggestion of REHN to empty the bowels of gas by introducing a stomach tube into the stomach.

We commend these views of Kummell to our readers, for we share his conviction that laparotomy for internal obstruction is a justifiable operation, and that long delay in undertaking it is more dangerous than the operation itself, if good judgment and skill are used in its performance.

SOME POINTS IN THE CARE OF CHILDREN.

A writer in the St. Louis *Globe-Democrat*, evidently a discreet medical man, says some things so true and so important for physicians to appreciate, that we think it well to repeat certain of them for the benefit of our readers. In the first place, he dwells upon the value of putting children early to bed, and having them rise soon after they wake. He holds that it is not only cruel, but also mischievous, to compel children to lie awake in bed for hours to prevent them from disturbing older people. The morning sun is most essential to plant life. It is equally true that the morning sun is most valuable for animal vigor, and this includes human beings.

Again, this writer opposes study late in the afternoon, and much more in the evening, for young children; and emphasizes, by a striking illustration, the advantages of play for children, instead of straining their little brains. He also expresses what we regard as a wise disapproval of putting children to bed immediately after supper. Let them, he says, have a chance for light exercise and sport after the meal. Above all he deprecates the stormy season which often follows supper, when the parents wish a child to go to bed and the child does not want to. We appreciate, of course, the advantages of discipline and regular habits; but we agree with the writer referred to in deprecating the practice of forcing a child to bed immediately after the last meal of the day.

One more point which we would refer to in this interesting article is that each child should, if possible, have a bed to itself. For

physical and moral reasons we believe this to be desirable; and we share the writer's convictions that the habit of sleeping alone is one which is advantageous to adults also.

As those who have great opportunities for molding the future of the children committed to their care, our readers will estimate at their proper worth the homely truths which we have just cited; and no good physician, we are sure, will consider it beneath the dignity of his calling to study matters which are so important to the happiness and welfare of the "little ones."

DURATION OF LIFE IN MODERATE DRINKERS.

The great insurance companies of Great Britain have, by their official action, pronounced the teetotalers longer lived than those who make even a moderate use of spirituous liquors. The companies in question have for a series of years kept separate registers of all their beneficiary members, the total abstainers being classed apart from the moderate drinkers. As a result of these records, they find the advantage in respect to longevity decidedly in favor of the teetotaler. One of the largest and oldest of these companies, which has kept separate registers for twenty years, declares that, among the strictly abstaining class, the real mortality has fallen short by 30 per cent. of the ordinary expectancy; while fully 99 per cent. of moderate drinkers have attained this expectancy. Caine, a member of Parliament, concludes, from a study of statistics, that the total abstainers have an average duration of life exceeding by six years that of moderate users of even the lighter alcoholic beverages, such as wine and beer. There are now insurance companies and societies for mutual aid in England designed exclusively for total abstinence men; the taking of even an occasional glass of any intoxicant vitiates their policy.

—The People's Medical Service Society of New York city has been recently incorporated. The capital stock is \$12,000. The incorporators propose to furnish medical aid to laborers and people of moderate means.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

ON THE ANIMAL ALKALOIDS, THE MAINES, LEUCOMAINES AND EXTINCTIVES IN THEIR PATHOLOGICAL REACTIONS. By SIR WILLIAM AITKEN, M.D., F.R.S., Professor of Pathology in the Medical School (Netley). Small 8vo, pp. v. Philadelphia: P. Blakiston, Son & Co., 1887. \$1.00.

This is a convenient manual upon a subject which is not very clear at the best, and of which medical men have but a hazy conception. It treats the rôle of poisonous alkaloids generated within the body, somewhat at the expense of what is known of the germ-theory, in regard to which the author seems to be decidedly skeptical. In commendatory opinions to the consideration of our readers, we think it just to call their attention to the fact that the advocates of the germ theory think it begging the question to distinguish between the effects of the poisonous alkaloids which microbes produce and the effects of the microbes. It is as if one were to charge the assassin with the crime of the assassin.

In concluding our notice of this book, we commend the example it furnishes, and the advantages, to medical men in the army and navy to the opportunities they have for the study of important sanitary questions. It is a great pity that so many army and navy surgeons fall into habits of idleness regard to medical science, as soon as they get out of the stimulus of examinations. If all would follow the example of a few, medical science would be benefitted almost beyond computation; they would gain eminence instead of relapsing so many do—into obscurity.

SURGICAL PATHOLOGY AND MORPHOLOGY. ANATOMY. By ANTHONY A. BOWEN, F.R.C.S., Surgical Registrar and Demonstrator of Surgical Pathology at St. Bartholomew's Hospital. Small 8vo, pp. xvi, 543. Philadelphia: P. Blakiston, Son & Company, 1887. Price, \$1.00.

This volume is of convenient size for the student, and it would make a very instructive companion for medical practitioners who like a book any where, and who have the time-saving eye-straining habit of reading as they ride. It is clearly printed, and arranged with catch-words in bold faced type. It is full of sound teaching in pathology, and remarkably complete for so tentative a work. It contains 135 original illustrations, which are sufficiently clear to add materially to the value of the text.

600 MEDICAL DON'TS; OR, THE PRACTICIAN'S UTILITY ENHANCED. By F. C. VALENTINE, M.D., Ex-Surgeon-General of the Army of Honduras, etc. 6x5 inches, pp. 128. New York: G. W. Dillingham, 1887.

The author of this little book has put into pithy sentences a large number of truths upon health and disease. With most of them we heartily agree; some of them we think extremely for example: "Don't, if you can avoid it, enter a hospital unless it is on the pavillion or cottage plan." "Don't hesitate to call disease 'sin'; it is your sin, your parents', your grand-parents', or your grand-parents'; it is sin." In the main, however, we can commend these injunctions to the attention of

readers, and believe that patients would be more reasonable and easier to manage if they could be made to properly digest such a book.

LITERARY NOTES AND QUERIES.

In this column the REPORTER will publish short literary items of interest and questions addressed to this Journal's readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—An old subscriber writes, asking us to send him a list of all the better works published in German

English on Hypnotism, with which we are acquainted. We regret that we cannot find time to do this; but are glad to inform our correspondent and of our readers that just this sort of work is done in an admirable manner by *The Bureau of General Information*, Joseph B. Marvin, Manager. P. O. Box 379, Washington, D. C. The investigations of this Bureau are conducted with the unrivaled resources of the Government Libraries at Washington.

CORRESPONDENCE.

Diphtheria.

MED. AND SURG. REPORTER:

Sirs:—In the REPORTER of November 25, 1887, p. 21, I find the following question: "Is there a pathological condition that you can truthfully call *diphtheritic croup*?"

Having had considerable experience in this matter, I venture to give you the result: To begin with, there is no diphtheritic croup; there is a croupous diphtheria (this is one of the divisions of Oertel, in "*Ziemssen's Cyclopedia of Medicine*"). When the larynx is filled with diphtheritic membrane, you have the same conditions practically which obtain in membranous croup. Hence the term.

In regard to treatment, I use French Brandy, tincture of iron and quinine in pretty large doses from the beginning. Most authors advise not to give stimulants until the patient is about exhausted. My experience is to the contrary. I give them from the beginning. Tincture of iron I also give from the beginning, in sweetened water; but I do not mix the two, because the brandy will form a precipitate of iron. Quinine I give in doses of 2 to 10 grains every 3 to 4 hours, according to the age and strength of the patient, until cinchonism is produced. After that, I continue it in tonic doses. Chlorate of Potash, used internally, I have learned to avoid, as I find it to produce nephritis almost invariably. I have tried it in small doses.

The gargle must be soothing and not irritant.

ting ; and all irritating measures, such as forcibly removing the membrane or violently swabbing the throat, *must* be avoided, as they only make matters worse.

Where the membrane has invaded the larynx (croupous diphtheria), I use a steam atomizer, and find a little fluid extract of ipecac to increase the virtues of the steam. The danger in cases of croupous diphtheria lies in the fact that the membrane fills up the larynx to such an extent as to prevent the entrance of air, and anything which will loosen the membrane, and cause it to be expectorated, will of course give relief.

Intubation of the larynx I have never tried, but it is very plain that there is great danger of pushing the membrane before the tube and thus causing the very result you try to avoid. I have had very few cases of croupous diphtheria since I have adopted the plan of treatment outlined above, and they recovered under the treatment I have indicated. Externally, I use a counter-irritant, such as salt pork, or coal oil, or something of that sort. The diet should be plain, nourishing and digestible.

Trusting that this may be of benefit to some one, I am, fraternally yours,
Huron, O., Dec. 1, 1887. JOST P. ESCH, M.D.

Hemorrhage into an Intra-Peritoneal Pus Cavity.

EDS. MED. AND SURG. REPORTER:

Sirs:—I have met with another, to me, singular case. If of any interest or use to you, use it accordingly.

On October 23, 1887, I was called to see Miss S., 19 years old. She was complaining of pain over the cæcum, indicating acute local peritonitis. The muscles of the abdomen on that side were so tense that not much could be learned by palpation, but I thought there was a boggy feeling in the part. The pain, which was controlled by two or three quarter-grain doses of morphine in twenty-four hours, was followed for three days by symptoms of collapse: cold extremities, thready and frequent pulse (180 per minute). In short, her appearance was as one suffering from a concealed hemorrhage. After reaction, her temperature ranged from 100° to 101½°, being highest between 8 to 12 P.M.

Tenderness now extended gradually over the whole abdomen. There was tympanites, but not much of it. The patient suffered with acute pain when not under the influence of morphia, but the pain was easily controlled. In spite of treatment, the girl became gradually weaker until November 3, when she died.

An *autopsy* was made three hours after death. The body was plump; one inch of fat between integument and abdominal muscles; peritoneal surface bathed in a thin, dark, fetid mixture of blood and pus. On the right side, between the ascending colon and the wall of the abdomen, I found a pus cavity capable of holding more than a quart. It extended from the pelvis to the liver, the cæcum and descending colon being so adherent to surrounding parts as to form the inner wall of the abscess. The right kidney was situated under the liver, and against its posterior border; the left kidney was in its normal position. The pus cavity extended to the lower surface of the liver and round behind the viscera to the spinal column, ulceration having laid bare the stellate ligament behind the psoas magnus muscle. The quadratus lumborum muscle was apparently destroyed. There was an ulceration over the head of the colon, which exposed the mucous membrane, from the outside, over a space as large as a finger nail. The mucous membrane seemed to be necrosed, but it had not given way. The pus cavity was lined with a thick, old pyogenic membrane, and filled with an old, black blood-clot. Fluid injected into the aorta, welled up from the bottom of the cavity close to the crest of the ilium, showing where the hemorrhage had come from.

My theory of the case is that the abscess burst into the peritoneal cavity at the time of the acute pain on October 23, and that when the pressure on the ulcerated arteries was thus removed the cavity filled with blood, which displaced the pus into the abdominal cavity.

The singular thing about the case is that such serious and extensive disease could have been there for so long a time, and produced no decided symptoms. The girl had continued to perform her usual work (housework) up to the evening of October 22; she had menstruated normally a few days before; her bowels were regular, and her appetite was fair.

She had consulted me two months prior to this attack, complaining of pain at the angle of the right scapula, and tightness across the upper part of the chest; but with no symptoms referable to abdomen or pelvis. From the white waxy look of her skin, I at first suspected something wrong with her kidneys, but a thorough examination of her urine disclosed nothing abnormal. I put her upon a tonic, under which she apparently improved until the sudden attack of pain on the 23d.

Yours truly, A. ADY.

Muscatine, Iowa, Nov. 5, 1887.

Effect of Taking the Reporter.

EDS. MED. AND SURG. REPORTER:

Sirs:—Your journal and circular received. While I neither question the age or value of the MEDICAL AND SURGICAL REPORTER, I must confess my inability to scan its pages. Of the four or five journals sent me have, from a lack of time, been unable to read them. Am everlastingly busy.

Yours, etc., L. S. C.

Negaunee, Mich., Nov. 21, 1887.

[This letter contains one of the most convincing testimonials to the value of the REPORTER which we have ever seen. About a month ago, the writer had so much leisure that he requested us to send him specimen copies of the REPORTER for a month *free*; and already his practice has increased to such an extent that he has no time to read. If this case gets noised abroad, we fear we shall never be able to satisfy the demand for specimen copies of the REPORTER; but we hope that other men to whom it brings such good luck will consider it worth at least the cost of a year's subscription, and will think, within themselves: "If four numbers of the MEDICAL AND SURGICAL REPORTER improve one's business so, what would fifty-two numbers do!"—EDS. REPORTER.]

NOTES AND COMMENTS.**Massage, Rest and Position in Sciatica.**

Mr. A. Symons Eccles, in a paper on a massage, rest and position in sciatica, which is contained in the *Practitioner*, November, 1887, reports the following case as illustrating the usefulness of this method of treatment. The patient was a man, fifty-four years of age, who, in a drive on the outside of an omnibus, had sat upon a damp cushion, and had been exposed to a heavy shower of rain. During the following night he developed pain of a burning character down the back of the thigh, which prevented rest and sleep. For six weeks he was unable to move without great pain, and for the greater part of that time was confined to bed. Poultices, anodynes, blisters, and even the actual cautery were tried, with only temporary relief. Worn out by suffering, and with the remedies employed, the patient insisted upon having massage tried, although Mr. Eccles could not advise it. He, however, agreed to try it, if the patient would follow out his directions in other respects. This proviso was made because the patient for some weeks had risen every morning and spent the day in the chair, with the affected limb propped

on another chair, and surrounded with pillows and air-cushions.

An examination of the affected limb at this time showed that the thigh on the affected side was an inch larger in circumference than the other one; that the ham-strings were contracted and hard, while the skin over the course of the sciatic nerve was thickened and scarred. Slight pain was elicited on pressure along the trunk of the nerve, and great pain at a spot about the middle of the thigh, extending downwards for about two inches. Absolute rest in bed was rigidly enforced, the leg was slung in a Salter's swing, and the whole leg protected from cold with flannel.

Eight minutes' massage of the limb was administered on the first day, but only *effleurage* (gentle superficial friction) over the course of the nerve. This was well borne, and no after-pain resulted; and, although there was much restlessness at night, the patient on the next morning expressed his sense of comfort from the use of the splint. Massage was again employed, the thumbs only being used over the sciatic trunk; but more vigorous handling of the limb than on the previous day was unattended by any untoward symptom, though the patient cried out at times during the process.

For ten days rubbing and kneading of the limb was carried out for periods varying from ten to twenty minutes. On the third day rapid *tapotement* (tapping) along the nerve trunk was added to the other manipulations, and included after that date in all the subsequent sittings, the limb being replaced in the swing after each day's treatment. On the tenth day the circumference of the thigh at the point of measurement was reduced by half an inch, and the rigidity of the ham-strings was less; while there was a marked difference in the color of the skin, that of the affected limb being much ruddier than on the other side; while the surface temperature, which had been lower than normal, now reached and maintained an equality with that of the sound limb. An attempt to straighten the knee caused much pain; though, when the limb was at rest, all sense of discomfort was lost, and the patient was now able to procure short intervals of sleep without the aid of drugs. General corporeal massage was now given, in addition to the special manipulation of the limb; and, as time went on, natural sleep was procured, the appetite improved, and the bowels, which had been obstinately constipated, were regularly relieved by the use of small doses of the granular efferves-

cent sulphate of sodium, taken in half a tumbler of warm water every morning.

On the twentieth day, passive movement of the affected limb, although causing some pain, was cautiously employed, and the limb swung at a more obtuse angle. A bad night followed; but the general condition of the patient was so much improved that the manipulations were continued, the knee gradually straightened, and the limb swung at a lower level day by day, until the twenty-eighth day, when the swing cradle was discarded. The patient now slept fairly well, and experienced much less discomfort on moving; the spontaneous pain, which had been troublesome in the earlier stages of the treatment, ceased, though cramp in the hamstrings and calf-muscles still occurred at varying intervals. At the end of the fifth week the patient was allowed to get up, and active exercise of the limb was employed till the end of the sixth week, when the pain on movement was so slight that a change of room was afforded daily, the patient walking with the aid of a stick and moving the limb with much greater freedom than ever since the onset of the disease. General massage was continued till the end of the eighth week, at which period there was complete immunity from pain and tenderness, the only signs of disease being an occasional attack of cramp and a tendency to "pins and needles and going to sleep" of the limb if the trunk of the nerve was subjected to long-continued pressure at any point, as by the edge of a hard seat.

At the time of writing this paper, Mr. Eccles says that the patient has been free for more than six months from any return of the complaint from which he suffered so long and severely.

The author in the same paper reports three other cases, in which the treatment was also markedly beneficial. In concluding his paper he says, with reference to the method of employing massage: "The process must be initiated by as vigorous kneading as the patient can bear of the whole circumference of the limb, as far away above the focus of the disease as possible; in other words, the proximal lymph trunks and spaces above the seat of mischief should first be unloaded; and if this is achieved, the measurement of the limb should, after massage, reveal some slight diminution in the circumference; then, either on the same occasion or at the next sitting, the manipulations should be practiced nearer to the affected part and as soon as may be of the part itself; indeed, the whole limb should be dealt with

so as to induce and maintain a more rapid circulation through the vessels, both of blood and lymph, thus at the same time encouraging a more frequent renewal of nutrition and a more rapid absorption of effete material.

If this indication can be fulfilled, with the rest and freedom from external pressure afforded by the swing, it will, I trust, be found that other cases of sciatica than those cited above will yield to the massage, rest, and position treatment."

Obstetric Practice in Rural Districts.

In the *Edin. Med. Journ.*, November, 1887, Dr. Wm. Fairbanks writes a very sensible and practical paper on this subject. He says that he has kept a careful register of all his obstetric cases, and that the series reported at present comprises the cases treated between 1874 and 1884. He hopes that the statistics which he presents, while inadequate in themselves, may serve to modify in the direction of truth the equally insufficient data of other records.

The series comprises:—Natural labors, 538; operative labors, 107; total, 645. Forceps cases, 82; turning, 10; craniotomy, 10; induction, 5. Presentation:—Vertex, 614; brow, 1; face, 1; breech, 17; foot, 5; shoulder, 2; hand, 5. Maternal deaths, 5; infantile deaths: non-viable, 14; premature, 7; full time, 40. Mortality in forceps cases:—Mother, 1; child, 0. Twins, 8; placenta prævia, 3; placenta adherent or retained, 5; post-partum hemorrhage, 8; spontaneous evolution (7 months), 1; hydrocephalus, 1; intrauterine amputation of fore-arm, 1. Youngest mother, 14 years and 3 days. Longest interval between two pregnancies during married life, 21 years.

Of the five maternal deaths, none seem to be fairly chargeable to the accoucheur.

Turning now to the infantile mortality, this must be largely reduced before the accoucheur can account himself responsible for it. Deduct cases in which the fœtus was not viable, 14; cases in which the child was born before Dr. Fairbanks was called in, 11; cases in which the child had long been dead, 6: total, 31; and the infantile mortality for which he is accountable is 30, or nearly 5 per cent. The causes of death in these thirty cases were:—Premature birth, 6; ante-partum hemorrhage, 5; craniotomy, 8; turning, 1; prolapsed funis, 2; prolapsed funis and turning, 3; breech presentation, 1; hydrocephalus, 1; induction, 2; induction and turning, 1: total, 30.

With reference to craniotomy, he says: "Many things must happen, and a new ge-

eration arise, before the various cutting operations will supplant craniotomy in moderate degrees of pelvic contraction." For this he gives the following reasons: 1. Craniotomy in such cases, when done at the proper time, and carefully, does not add appreciably to the mother's risk; 2. The cutting operation does add to the mother's risk, and she and her friends know it; 3. Patients refuse to be operated on.

With reference to the use of forceps, he says that the more frequently a practitioner uses the forceps, the larger in all probability will be his proportion of easy forceps cases, and therefore his statistics will look better, in this respect, than those of a man who postpones the use of the forceps until the case is desperate. Yet it may reasonably be a subject for inquiry, whether any percentage of instrumental interference should lay one open to the charge of meddlesomeness. His rule is never to interfere except in the best interests of mother and child, and never merely to save his own time. This is the best and only test a practitioner need regard, and, in applying it with cultivated judgment, he has no censor but his own conscience.

As to the time at which it is desirable to interfere instrumentally in labor, Dr. Fairbanks says: "The length and character of the first stage helps to determine the point. The strength and temperament of the patient are also factors in the case. But the great question to be settled is this: Are the pains telling upon the patient in a degree out of proportion to their effect upon the progress of labor? If they are, it will not be very long before help is called for." He seldom allows strong expulsive pains to go on for more than one and a half or two hours after full dilatation of the cervix, unless they are manifestly equal to the occasion; and if pains become feeble, after having been in good force for an hour or so, the forceps are generally resorted to.

With regard to the use of ergot, he says: "In three-fourths of the foregoing cases the older practitioners would have used it, and sooner or later, let us hope, the babies would have been born; but the mortality table would probably have been very different. Angus Macdonald's words in, if I mistake not, his first course of lectures to four of us students, have a permanent place in my memory,—'In midwifery practice always prefer steel to ergot.' And so I have. My rules for giving ergot have been: Never give it to a tired uterus. Never give it in a first labor. Never give it in a case of grave disproportion. Don't give it in cases of slight

disproportion. Hardly ever give it till the head is born. From the present series of cases it would be easy to illustrate and establish these rules, but I fancy they are almost generally accepted."

He is in the habit of inducing labor by means of the elastic rubber catheter or with Barnes's bags. Chloroform, he says, is seldom needed for the women among whom he has practiced—even in forceps cases, turning or craniotomy. He speaks disparagingly of the value of chloral as an anodyne in painful and tedious dilatation of the cervix.

With regard to rupture of the perineum, he does not seem to think that sewing up of slight tears is necessary. He speaks confidently of having saved severe lacerations by using the forceps, while the bad tears which occurred were in cases in which the forceps had not been applied.

Those Leprosy Cases.

The following communication has been sent by a number of physicians to Dr. Arthur Van Harlingen, who was recently fined \$100 by the Board of Health for not reporting two cases of leprosy under treatment by him:

"As fellow-physicians, we are unwilling that you should be personally responsible for the payment of the fine which the Board of Health has, we think, unjustly imposed upon you. We, therefore, take great pleasure in enclosing you, for the purpose of reimbursement, and as a mark of our continued respect and appreciation of your personal worth and professional skill, a check for one hundred dollars.

"Although not desiring to commit ourselves collectively regarding the contagiousness of leprosy, we realize the fact that, in the past twenty years, lepers in variable number have been treated in various European and American cities without a known instance of contagion thereby. We feel, therefore, that the action of the said Board was, under the circumstances, unjust to you and to your patients."

The communication was signed by Doctors

Inhalation of Sulphurous Acid in Tuberculosis.

At the meeting of the Therapeutical Society of Paris, July 27, 1887. Dujardin Beaumetz stated that he had been experimenting with inhalations of sulphurous acid after the method employed at the hospital of Cherbourg. He burns in a close room 300 grains of the flowers of sulphur for every cubic yard of space. He then puts the patients in this room twelve hours afterwards, and allows them to stay there eight hours. Under this treatment the bacilli disappear from the sputum, which, from being yellow, becomes white, while sleep is better. This method has been tried for about ten days at the Cochin hospital, where it has already given some good results.

At a subsequent meeting of the Society. October 12, 1887, he stated that up to that time the inhalations had diminished the expectoration in one group of cases, encouraged another to persevere, while in a third they had increased the suffering, or at least were disagreeable.—*Progrès Médical*, October 22, 1887.

Not Due to Vaccination.

Alfred S. Gubb, L. R. C. P., writes to the *British Medical Journal*, Nov. 5, 1887, and congratulates himself upon having made a lucky escape. He says: "I was asked by a lady, whom I had attended in her confinement two months before, to vaccinate her baby, as she was going into the country. I thought it preferable to await her return, and postponed the operation. It was well I did so, for within three or four days the child developed a violent attack of desquamative dermatitis, and for a week or two presented a most pitiable appearance, with the skin hanging all over it in rags and tatters. The child recovered in the course of two or three weeks, but it can easily be imagined what would have been the verdict had I been unfortunate enough to have vaccinated the child. As it was, the mother asked me 'Was I sure I had not vaccinated the child?'" This is another example of the errors so commonly resulting from *post hoc* conclusions.

Fatty Degeneration due to the Opium Habit.

The Paris correspondent of the *Medical Press and Circular*,* Nov. 9, 1887, states that M. Ball has made a communication to the Académie de Médecine of Paris on certain anatomical lesions which he has noted

in the persons of those who are addicted to morphine. A woman voluntarily entered his service at St. Anne in order to be cured of the habit of taking morphine. The dose she took daily was about sixteen grains. At first immediate suppression of the drug was ordered; but the patient fell into such a state of collapse that a more moderate and progressive treatment had to be adopted. Sleeplessness and agitation were combated by enemata of bromide of potassium and chloral, and four grains daily of sparteine had to be given for the heart. The treatment lasted forty-two days, and, at the end of that period, the woman seemed to have quite recovered. But, when she was about to leave the hospital, she suddenly died. The autopsy revealed fatty degeneration of almost all the internal organs, especially of the heart, and the presence of morphine in the nervous centres.

The Prevalence of Venereal Diseases in the British Army.

From the publication of the Medical Department Reports of the British Army in the *Brit. Med. Journal*, it is learned that venereal diseases continue to be a prolific source of admission into hospital and inefficiency. Primary syphilis caused 11,095 admissions to hospitals among the troops in the United Kingdom during the year 1885, and secondary syphilis 2336 admissions. These figures give ratios of 127.4 and 26.8 per 1000 respectively. There were also 10,561 admissions into the hospital for gonorrhœa and its sequelæ. These being included, the ratio of admission for all forms of venereal disease was 275.4 per 1000, which is higher than the ratio in the previous year by 4.7, and then the average rate for the preceding six years by 33.9 per 1000. The figures quoted sufficiently show that the large proportionate numbers of hospital admissions which occurred after the abolition of the Contagious Diseases Acts were abolished, are still maintained. The returns from different military districts exhibit considerable variations in the ratios of prevalence of syphilitic affections, ranging from 189.8 per 1000 in the Dublin district to 51.2 per 1000 in the Cork district. An increase in the ratio of prevalence of primary syphilis is especially noted in the Home district. The highest rates of prevalence of gonorrhœal affections were 160.5 per 1000 in the Dublin district, 148 in the Channel Islands, and 129.7 per 1000 in the Northern district.

Paroxysmal Sneezing.

A correspondent writes to the *British Medical Journal* as follows: Some patients have periodical attacks of sneezing in the evening, but generally there is some cause which must be removed. To give relief and stave off the attacks, a very good plan is to smear the nostrils with a little vaseline. This will, in some people, act like a charm; in others, concentrated spirits of camphor, "a saturated solution," stronger than the preparation of the B. P., painted with a camel's hair brush up the nostrils and over the alæ of the nose. If neither of these remedies succeeds, sometimes tr. opii rubbed with the finger over the bridge of the nose, alæ, and cheeks will. But these remedies can only be considered palliative, whilst general treatment of the Schneiderian mucous membrane is persevered with in the daytime.

Formula for Terpene.

At the meeting of the Therapeutical Society of Paris, on July 27, 1887, M. Vigier recommended the following formula for terpene, which contains seven and a half grains to the teaspoonful:

- R Honey,
Glycerine.....of each 100 grs.
Alcohol (95 %),
Terpine.....of each 7½ grs.
M. Sig.—Teaspoonful, a dose.

The terpene remains dissolved if mixed in the strength of a teaspoonful to a glass of water. A smaller amount of water than this causes the terpene to precipitate.—*Progrès Médical*.

Parenchymatous Nephritis in Children.

Authors are not agreed as to the frequency of chronic parenchymatous nephritis in children. According to the *Lancet*, Baginsky and Ferreira are two of the most recent authors who believe that the disease is not infrequent. The latter regards diseases of the skin, especially of an impetiginous or ecthymatous character, which involve an extensive area of skin, as frequent causes of this form of Bright's disease. The treatment which has proved of most value is the use of astringents, like tannin, perchloride of iron, iodide of starch, and diuretic salines—agents which increase the quantity of urine while they diminish the amount of albumin. Rectal injections of cold water were also employed with benefit; and inhalations of oxygen should not be forgotten.

News Items.

—Small-pox has broken out at, and near, Catasauqua, Pa.

—Typhoid fever, of a mild type, is said to be prevailing at Pittsburg, Pa.

—In consequence of a prolonged drought, about the end of November, the water supply of Plainfield, Ind., has become so impure that typhoid fever of the worst type is developing, and in some other localities the scourge is epidemic.

—The *Pioneer-Press* of St. Paul, Minn., learns from Rathsay, Minn., of the existence near there of two cases of leprosy of the most loathsome type, being that known to medical men as "elephantiasis mutilans." Both patients are Norwegians, and no other members of the family have the disease. Before leaving Norway, both men were fishermen, and lived almost exclusively on a fish-diet, to which they attribute their affliction.

—An epidemic of typhoid and malarial fever is prevalent in Ottawa, but it is said to be of a mild type. The citizens and the clergy are becoming seriously alarmed, and are disposed to blame the physicians for not giving a satisfactory reason for the causes of the epidemic. The number of typhoid and malarial fever cases in the city is enormous. Many people think it is a low calculation to place the number at 500. It is stated that the doctors are almost run off their feet.

—A writer in the *Sanitary News* has a good word to say for sewer gas. He thinks it is the outside air which contaminates the sewer gas with micro-organisms. "Sewer air," he says, "has commonly been supposed to be 'loaded' with micro-organisms, whereas, in reality it turns out to be some of the freest air from micro-organisms that can be found." May be he is right, but he will find it hard to convince the housekeepers of America that their fears of sewer gas have been groundless.

—The correspondent of the *British Medical Journal* writes from Switzerland that Dr. Sahli has communicated a very interesting, and probably unique, case of gonorrhœal cutaneous metastasis. In a male patient, who for two months had suffered from gonorrhœa, there appeared two abscesses, as big as a man's fist, situated in the region of the knee joint. The gathering having been incised, a quantity of sanguinolent pus escaped. The microscopical examination of the latter revealed masses of typical gonococci embedded, as

usual, within pus-cells. The abscesses healed without any complications.

—The Medical Faculty of Lyons, France, has only been in existence ten years, but it has been so successful that nearly 800 students are on the rolls. A number of these young graduates have taken prizes in competitive examinations, and only recently Professor Chauveau was taken from the Lyons faculty to be Professor of Physiology in the Paris faculty of medicine.

—The mammoth hospital in Seventh avenue, between Sixth and Seventh streets, Brooklyn, the gift of George I. Seney to the Methodist Episcopal Church, was dedicated December 15. With the exception of the Johns Hopkins Hospital in Baltimore, the Seney Hospital, it is said, will be the largest and best equipped in the world. Mr. Seney originally gave \$200,000 to found the institution in 1881, but he expended in all the sum of \$410,000.

—The Sultan of Turkey has conferred the decoration of Commander of the Medjidie on Dr. Morris H. Henry, of New York, for distinguished contributions to medical and surgical science, some of which are of especial service in the Ottoman Empire. It is a long range command, as the Medjidie is an amiable body, requiring no personal attendance on his part.

—Dr. Sommerbrod, of the Breslau University, an eminent laryngologist, lectured on the case of the Crown Prince, in Berlin, December 6. He is inclined to the conclusion that is a case of simple perichondritis, with abscess formation, and not of a cancerous nature; though some difficulty is likely to be presented in the extrusion of several pieces of dead cartilage. He said the prospects of the Prince's recovery were hopeful.

—There is trouble in the surgical and medical staff of St. Francis Hospital, Jersey City, over the selection of a successor to Dr. T. R. Varick, who was medical director of the institution when he died. The hospital is conducted by the Sisters of the Poor. The physicians who attend it are volunteers, and up to four years ago the joint staff elected their own director. Then a change was made and the director was selected by the Bishop of the diocese, the Sister Superior and the priest of the diocese in which the institution is located. The medical and surgical staffs are composed of four physicians each, and the director is usually selected from the surgical staff. The joint staffs held a meeting

on Thursday evening, and Dr. Finn, of Greenville, presided. A letter was received stating that Dr. John D. McGill had been chosen to succeed Dr. Varick. The letter was signed by Bishop Wigger, the Rev. Father Senez and the Sister Superior. As soon as it was read Dr. B. A. Watson resigned from the staff. He and Dr. Magill are the oldest in service on the staff. Dr. Watson refuses at present to give his reasons for resigning, but says that Drs. Finn, Payne and Dickinson had told him that they would also resign.

—Under the high license law of Illinois the number of saloons in the State has been reduced from 13,000 to 10,000, and the revenue from the liquor traffic has increased from \$700,000 to nearly \$5,000,000. From this increased revenue the cities of Chicago, Springfield, Peoria, Quincy, Bloomington, and Jacksonville have been enabled to pave their streets, beautify their parks, and improve their police force and sanitary condition.

—John H. Pickett, a member of the Iowa Pharmacy Commission, said that their report would show about 1600 registered pharmacists in the State. Of these only about 700 held permits to sell intoxicating liquors. When the law was put in force in 1880 there were 2400 druggists in Iowa. One year ago there were nearly 1800, and, in spite of the fact that about 500 certificates to new pharmacists were issued during the year ending last April, yet the number of certificates in force to-day is smaller than ever before. This is owing in large part to the number revoked by the Commissioners. A large number of drug-store saloons have been closed, and there are now pending a number of fines against druggists, one being for nearly \$400, which are awaiting a decision of the Supreme Court.

—Professor Seguin and Dr. Godfrey dissected the carcass of the elephant Alice, burned in the fire at the Barnum & Bailey winter quarters in November. In the stomach was found over 300 pennies, part of a pocket-knife, four cane ferules, a piece of lead pipe, and some pebbles.

—It is reported from Summertown, S. C., that a colored girl, 17 years old, who was supposed to have died, was taken for burial to a cemetery. At this point a noise, like the mewing of a cat, was heard proceeding from the coffin; when it was opened, the girl was discovered to be living, and to have just given birth to a living child. At last accounts, the *Cincinnati Inquirer* says, mother and child were doing well!

HUMOR.

ELDERLY MAN (staring at immigrant who has just landed)—What a singular-looking person! His face is all covered with little depressions. Was he born that way do you think, or was he captured by savages and mutilated?

Bystander—Captured, nothing! That man once had the small pox, that's all. Didn't you ever see a man pitted like that before?

Elderly man—Small-pox? Ah, that is something like cholera, is it not?

By-tander (impatiently)—Jumpin' Jerusalem, man, where have you lived all your life?

Elderly man (with dignity)—Sir, I am a member of the New York City Board of Health.

A WICKED URCHIN'S STRATEGY.—A nine-year-old Eagleville (Conn.) boy was belated at Coventry, several miles from his home, the other night, and being afraid to go home in the dark, put his Yankee wits to work. Pretty soon a doctor of the place was informed by a small boy that a well-known citizen of Eagleville was very ill with typhoid fever and wanted him to come to him immediately. The doctor said he'd go after supper and asked the lad to join him at the table. The boy did so, and soon after was snugly tucked by the side of the doctor in his carriage and rolling homeward. When they arrived at the house of the alleged sick man the boy scrambled out, and the doctor followed and knocked at the door. The citizen himself, in his usual health, opened it. He hadn't been sick and hadn't sent for the doctor. Then they looked for the boy. They couldn't find him. He had had his supper and ride home and was well out of the way.

—ARAGO'S JOKE.—Even great scientists sometimes enjoy their little joke. The story goes that one day at the French Academy of Sciences, when there was a long and tiresome debate, Arago thought he would go out and take the air. At the foot of the stairway there was a leather bowl, upon which the rays of the sun were hotly beating. Arago turned the bowl around, and rushing upstairs, told the distinguished assemblage that he had just met with something that was very mysterious. "That leather bowl," he said, at the foot of the stairway is cool upon the side which presents itself to the sun, but warm upon the other." The scientists descended in a body and substantiated this assertion. They took the inclination of the sun, the hour, the minute, the second, and a vast array of other details. They made calculations, and several weeks

afterward each of them presented a paper explaining the phenomenon, Arago himself taking care to send in his explanation with the rest. There is no knowing how far the discussion might have gone had it not been for the doorkeeper, who, having seen Arago turn the bowl, and pitying the worthy gentlemen who were so much worried, cleared away the mystery.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Dec. 6, 1887, to Dec. 10, 1887:

Major G. M. Sternberg, Surgeon, assigned to duty as Attending Surgeon and Examiner of Recruits at Baltimore, Md.

Major P. J. A. Cleary, Surgeon, assigned to duty at Fort Wingate, N. M.

First Lieutenant C. L. G. Anderson, Assistant Surgeon, assigned to duty at Fort McDowell, Ariz.

Capt. A. W. Taylor, Assistant Surgeon, assigned to duty at Fort Robinson, Neb.

Capt. A. H. Appel, Assistant Surgeon, assigned to duty at Camp at Highwood, Ill., relieving Assistant Surgeon H. O. Perley.

Capt. H. O. Perley, Assistant Surgeon, will rejoin his proper station, Fort Wayne, Mich. S. O. 285, A. G. O. Dec. 8, 1887.

Capt. John Van R. Hoff, Assistant Surgeon, granted leave of absence for 1 month, to take effect on or about the 12th proximo. S. O. 128, Dept. Mo. Nov. 30, 1887.

Capt. Benjamin Munday, Assistant Surgeon, granted leave of absence for 1 month, to take effect about Dec. 15, 1887. S. O. 280, A. G. O. Dec. 2, 1887.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Dec. 12, 1887:

J. M. Gassaway, Surgeon, when relieved to proceed to Cairo, Ill., and assume charge of the Service. Dec. 9, 1887.

Fairfax Irwin, Surgeon, promoted and appointed Surgeon from date of oath, Dec. 10, 1887. Dec. 8, 1887. * To proceed to Pittsburg, Pa., Wheeling, W. Va., Gallipolis, Ohio, Evansville, Ind., Cairo, Ill., Little Rock, Ark., Shreveport, La., New Orleans, La., Rome, Ga., Chattanooga and Nashville, Tenn., as Inspector. Nov. 12, 1887.

John Guitéras, Passed Assistant Surgeon, when relieved, to proceed to Charleston, S. C., and assume charge of the Service. Dec. 12, 1887.

C. E. Banks, Passed Assistant Surgeon, to proceed to Portland, Maine, and assume charge of the Service. Dec. 9, 1887.

D. A. Carmichael, Passed Assistant Surgeon, when relieved, to proceed to Washington, D. C., for temporary duty in the office of the Supervising Surgeon-General. Dec. 9, 1887.

A. D. Bevan, Passed Assistant Surgeon, granted leave of absence for 20 days. Dec. 7, 1887.

A. H. Glennan, Passed Assistant Surgeon, to proceed to Key West, Fla., and assume charge of the Service. Dec. 12, 1887.

There have been no Changes in the Medical Corps of the Navy, during week ending Dec. 10, 1887.

* Omitted from previous report.

ORIGINAL DEPARTMENT.

CLINICAL LECTURE.

ACNE.

BY HENRY J. REYNOLDS, M.D.,

Professor of Dermatology in the College of Physicians and Surgeons, Chicago; Professor of Skin and Genito-Urinary Diseases, Chicago Polyclinic.

Gentlemen:—We have here to-day a case, which, though it represents a very common disease, very well illustrates the subject which we are about to consider. You will recollect at a previous lecture the consideration of several diseases of the sebaceous glands, which were characterized mainly by functional disorder. To-day we proceed to a consideration of an inflammatory disease of those glands, known as *acne*.

Acne, is perhaps with one exception, the commonest of all skin diseases, and is an affection, the general appearance of which is undoubtedly familiar to all of you. It is that condition which is commonly known as "pimples on the face." While the favorite location, or principal seat of the disease, is the face, it may occur upon any portion of the surface of the body in which sebaceous glands are found. Ordinarily, however, the shoulders and chest are the parts principally affected when it is not confined to the face. The disease almost invariably first manifests itself about the age of puberty, and it rarely continues beyond the twentieth or twenty-fifth year. It is met with in both sexes, but is perhaps more common in the male. The characteristic lesions of the disease are papules and pustules. The papules, as in many other inflammatory affections of the

skin, are generally of a reddish color, each lesion usually representing the location of a sebaceous gland. There are very few subjective symptoms in the disease, there being neither pain, itching, nor other subjective sensation of any consequence. As the disease is an affection of the sebaceous glands, and the sebaceous glands are uniformly distributed throughout the affected region, so the lesions necessarily assume a symmetrical arrangement. Another very important characteristic observed during the career of this disease is what are called comedones, or popularly "black-heads;" a condition with which you are doubtless familiar. These small lesions are met with in every case of acne, distributed here and there throughout the affected locality, and they constitute one of the most important diagnostic points. The disease is of course not contagious in character. As a rule, it is self-limited, yet it naturally tends to become chronic, often lasting several years. Now, while the affection is chiefly a local one, or while it interests us particularly on account of its local manifestations, like very many other local diseases, it is always influenced, aggravated or prolonged, if not actually produced, by certain constitutional or remote causes. As a rule, however, there is not necessarily any serious constitutional disturbance in this disease. Frequently, digestive disorders, constipation, etc., are met with, and it seems highly probable that in many cases the disease depends largely on some disorder of the sexual or generative organs, such as menstrual disorders in the female, or congestion of the womb, and irritability of the urethra, especially of the prostatic portion, in the male.

Like many other forms of skin disease, various names are used to designate the different forms of acne, the so-called different forms receiving their name from the cause, the form of lesion, the location, or the stage of the disease. For instance, we have a form of acne known as *acne artificialis*, a form which generally assumes a universal character, and is produced by the toxic effects of certain drugs, as the iodide of potassium. *Acne papulosa*, in which papules are the predominating lesions; *acne pustulosa*, the character of the affection is pustular; *acne vulgaris*, the ordinary form of acne, in which both forms of lesions are almost invariably met with; *acne indurata*, in which the papules are large and deep, assuming almost a tubercular character, or the character of nodules, with little discoloration on the surface, and in which we generally find some pus deep down in the lesion (*acne cachecticorum*); and *acne rosacea*, which assumes a rosy or erythematous character—a form of acne usually met with late in life, and which, owing to its many distinct characteristics, will be hereafter separately considered.

The history of the case to which I now wish to direct your attention is as follows: The patient is a male, sixteen years of age, and, as you see, apparently in a fair state of health. He has had an eruption of this character on his face, with a few lesions upon the chest and shoulders, for about two years. He says he has never had sexual intercourse, and never practiced self-abuse. But on investigation of the sexual organs, we find that almost the entire glans penis, underneath the prepuce, is coated over by a thick mass of what is probably subcutaneous secretion, showing in a measure the relation between disorder of these organs and the disease we are considering; and on exploring the urethra with a bulbous metallic sound, we find it to be extremely sensitive, especially in the prostatic portion. As he passes around among you, I wish you to investigate the case with a view to discovering the features I have just mentioned as characteristic of acne. While it is at once evident to all of you that the case represents one of ordinary pimples on the face, it is necessary, in order to obtain a scientific knowledge of the affection—as certain other diseases assume similar characteristics—to consider the various manifestations carefully and individually. The location of the eruption and the age of the patient are at once suggestive. By closer examination you find the lesions to be papules and pustules, the skin between them being comparatively free from redness or other indications of dis-

ease. The patient gives no history of any subjective symptoms; a feature, the importance of which is recognized when we come to contrast it with certain other diseases, as eczema, for instance. You at once observe the symmetrical character here manifested. You see plainly and distinctly the numerous comedones or so-called “black-heads,” distributed, like the acne eruption, symmetrically over the face. There is, of course, no history of contagion. The chronic character of the disease is apparent from the fact that it has already existed in this case for two years. Further, while the condition of the genital organs just referred to, is not necessarily a symptom of acne, it is important to note such disorder, inasmuch as I have stated that it is frequently met with in the disease. I wish, furthermore, to call your attention to a few lesions in this case, which have almost a tubercular or nodular character, without much red discoloration. This form of lesion predominates in certain cases, and gives the disease the name *acne indurata*.

Etiology.—As regards its etiology, acne, like many other skin diseases, is probably due in a measure to both local and constitutional causes. With reference to the local causes, I may mention, first, impaired function of the sebaceous glands,—though this may itself be due to constitutional causes. But, impairment of function of the sebaceous glands once established in this particular locality, we have, as an almost natural consequence, a “plugging up” of the sebaceous ducts with sebaceous matter. The outer portion of this sebaceous plug becomes blackened, and constitutes what is known as a “black head” or a “comedone.” These, in time, apparently act as foreign bodies in that particular locality, and inflammation, swelling, and suppuration follow. Now, while many acne papules and pustules undoubtedly originate in this manner, it is nevertheless probable that some lesions arise independently of this cause. It is probable that the insufficient use of soap on the face, which should dissolve off the sebaceous secretion, and should facilitate its free exit, has much to do with the original trouble, which afterwards develops into true acne.

As already stated, in regard to the constitutional symptoms, we frequently meet with derangement of the digestive apparatus, constipation, anemia, menstrual, urethral, or genital disorders. But whether these conditions are actually causes of acne, or whether they, and likewise acne, all depend upon some other still more remote condition or not, it is difficult to say. It is well known

that the age at which acne first manifests itself—puberty—is a very important epoch in the life of the individual. It is the age at which the development or maturing of the reproductive organs becomes completed. The patient is in a transition period between childhood and adult life. This is an age at which there is necessarily a disturbance in the equilibrium of the nervous system. This condition of the nervous system has, I think, much to do with the development of the disease under consideration, if it is not also the true cause of the many constitutional or remote conditions on which acne is frequently said to depend: dyspepsia, constipation, menstrual and other sexual disturbances.

Another point, which should not be overlooked in considering the local causes of this disease, has reference to a very important physiological phenomenon which is observed at this age: namely, the development of the hairs, as of the beard, etc. The sebaceous glands lie in immediate contact with the hair follicles: the one being an appendage of the other. The development, or growth, of hair which occurs at this time of life naturally implies physiological activity of the parts involved: viz., the hair follicles and sebaceous glands. It is an established fact that any part or organ which is overtaxed, or in an increased state of physiological activity, becomes very readily impaired in function, and the physiological afflux of blood to the part may then produce a pathological condition or an inflammation of that particular locality. Now, when we find this state of affairs, and remember that there is already a want of harmonious equilibrium in the nervous system, as we have just endeavored to show, which presides over all functions, acne would seem almost a natural consequence.

Pathology.—Acne represents an inflammation of the sebaceous glands and peri-glandular structures, corresponding in a sense to the disease which I described a short time ago as *miliaria*, which represents an inflammation of the sudoriferous glands and peri-glandular tissue. Certain lesions met with in acne, generally embraced under the head of acne indurata, though giving no outward indication of an inflammatory condition, generally contain, deep down in the tissues, a small amount of pus, and are in reality small dermic abscesses.

Diagnosis.—The disease is at once recognized from the age of the patient, the location of the affection, the form of the lesions, its symmetrical distribution, the presence of comedones, and its chronic character. While, however, in ordinary cases a diagnosis may be

made with comparative certainty without considering any differential diagnostic points, there are cases in which it is necessary to differentiate this from other affections of the skin, the most important of which are sycosis, eczema, syphilis, and in some cases variola. By closely observing the following diagnostic tables, a diagnosis can always be made with positiveness:

ACNE.

1. Entire face.
2. Comedones.
3. Generally healthy skin between the lesions.
4. Papules and pustules not penetrated by a hair.
5. Little subjective sensation.
6. Puberty.

ACNE.

1. Little itching.
2. Skin generally healthy between lesions.
3. No scaling or crusting.
4. Symmetrical.
5. May be dry.
6. Comedones.
7. Puberty.
8. Generally confined to face.

ACNE.

1. No syphilitic history.
2. Puberty.
3. Generally confined to face.
4. Comedones and other sebaceous disorders.
5. No ulceration.
6. No crusting.
7. Bright red.
8. Lesions discrete.
9. Aggravated or unimproved by syphilitic treatment.
10. Lesions comparatively short-lived as a rule.

SYCOSIS.

1. Bearded portion only.
2. None.
3. Diffuse redness.
4. They are.
5. Pain and burning.
6. Adult life.

ECZEMA.

1. Intense itching at times.
2. General redness of skin.
3. Liability to both.
4. Patchy.
5. Watery exudation.
6. None.
7. Any age.
8. If on face, ears, scalp, other parts are pretty sure to be involved.

SYPHILIS.

1. Generally able to obtain a syphilitic history.
2. Generally in adult life.
3. May be general.
4. None.
5. May have.
6. There is.
7. Dark red or copper color.
8. May be in groups, arranged in circular or semi-circular manner.
9. Always improves under syphilitic treatment.
10. Lesions more stationary.

A differentiation from variola will perhaps only be necessary in the generalized form of acne which is sometimes produced by the use of the iodide of potassium internally. While this condition is not very common, it sometimes occurs even when a very small amount of the drug is used, and the pustules are so generally distributed and universal that there is in many respects a very striking resemblance between the two affections. In artificial acne we have to guide us a knowledge of the fact that the patient has taken the iodide of potassium or some other similar drug previous to the appearance of the erup-

tion; the more speedy development of the pustules; the absence of a history of exposure to small-pox, and of the fever and other constitutional disturbances which are characteristic of the latter disease.

Treatment.—Inasmuch as acne is a disease which, as a rule, does not respond very readily to treatment, very many remedies have been recommended by different observers at different times. There are certain general principles, however, which it is more important to remember in treating this disease than the numberless remedies said to be useful for it. As the affection is due to both local and constitutional causes, so the treatment must be both local and constitutional in character. As in all other diseases, it is well to keep in mind the cause or the pathological condition to be combated or removed. Acne may generally be temporarily relieved in a short space of time by certain local applications. Perhaps the most important remedies for local use are green soap, sulphur, boric acid, and bichloride of mercury. A plan of treatment, which will be found the most satisfactory, is to wash the face three times a day in water as hot as can be borne by the patient. After carefully washing in the morning and at noon, a soothing ointment may be applied,—as, for instance, ung. aquæ rosæ; or, instead, sulphuris loti, one-half drachm, to ung. aquæ rosæ one ounce; or, instead of the sulphur, four grains of bichloride of mercury may be incorporated, or a half drachm or a drachm of boric acid. After thoroughly bathing again with hot water and plenty of soap at night, green soap may be applied, and allowed to remain on over night. Or it may be applied in the form known as *spiritus saponis kalini*, which is about two parts of green soap to one of alcohol, filtered, and flavored with lavender. This preparation will often be found preferable to the pure green soap, inasmuch as green soap is sometimes too irritating to be tolerated for any length of time.

Since many of the acne lesions are due to a “plugging up” of the sebaceous ducts, it is always advisable in beginning the treatment to remove these plugs with what is known as a comedone extractor. As these comedones are constantly reproduced, or developed in other localities, the same process requires to be repeated every time the patient is seen. In many cases of acne I have found that the cure was much expedited by electricity applied to the affected parts, in the form of the Faradic or the galvanic current, preferably the latter, which, in order to be beneficial, should be carefully and judiciously applied,

at least once in twenty-four hours. Lancing freely with a small, sharp knife, will always be found to expedite the disappearance of the papules and pustules, and this procedure becomes absolutely necessary in the deep lesions of acne indurata. These indurated lesions require to be lanced very deeply, as they are sure to have pus down in the bottom. After lancing them, if the part were left undisturbed, they would immediately heal over on the surface and the pus formation would again go on in this miniature dermic abscess as before. It will, therefore, be seen that something further is necessary in the management of lesions of this character, and it is my custom invariably after lancing and squeezing out the pus to insert with a fine probe a small piece of absorbent cotton saturated with carbolic acid. This not only has a tendency to destroy the tendency to formation of pus in the lesion, but it helps to keep it open until healing takes place from the bottom. In this manner, the lesions are completely eradicated without leaving a perceptible scar, whereas, without surgical interference, they would continue indefinitely as indurated lesions.

The indications for constitutional treatment are numerous and vary with the cases. As we generally meet with digestive troubles, sexual disorders, or an anæmic condition, remedies suited to these conditions must be used. Constipation should never be allowed to continue during the treatment of acne. Among the remedies employed internally, which are supposed to have a direct effect upon the disease, are sulphide of calcium and ergot. The sulphide of calcium may be given three times a day in doses varying from one-fourth to one grain. This remedy is supposed to be useful in most pustular affections. The beneficial effects of ergot are supposed to be due either to an action upon the non-striated muscular fibres of the skin, or upon the vaso-motor nervous system, or to its direct action upon the uterus. Inasmuch as this drug has generally been found more useful in females than in males, it is probable that its efficacy depends more on its local action upon the uterus than upon any of its other ascribed virtues. It may be given in half drachm doses of the fluid extract three times a day, either alone or in combination with other drugs which are indicated by certain constitutional derangements. Arsenic, which has always been so popular a remedy in skin affections, and which has been recommended by some in this disease, I have found in my experience absolutely worthless. Vaginal douches of water as hot as can be

borne seem in many cases to greatly aid in the cure of acne. Likewise the occasional passage of a metallic sound in the male urethra, with a view to overcoming sensitiveness in the prostatic portion, seems in some cases to be a valuable procedure. Candies, pastry, and other sweet articles of diet seem almost invariably to aggravate acne and must always be prohibited.

The patient before you, who first came under our observation about two weeks ago, we have treated only by an ordinary laxative internally, and the passage of a full-sized sound into the urethra every few days, and there seems already a decided improvement. Some of the lesions have been lanced, however, in the manner I have previously described, and this, of course, is necessary in any line of treatment.

In conclusion, I may only add that you must never burden your minds in this or any other disease with a knowledge of specific remedies to the neglect of observation of remote or constitutional disorders, which, though they may not directly produce the disease, almost invariably aggravate or prolong it.

COMMUNICATIONS.

CATARRHAL VULVO-VAGINITIS IN CHILDREN.

BY THEOPHILUS PARVIN, M.D.,

Professor of Obstetrics, Diseases of Women and of Children, Jefferson Medical College, Philadelphia.

Within two weeks there have been presented at the dispensary for diseases of children of Jefferson Medical College Hospital, three girls, the oldest seven years of age, suffering with leucorrhœa. It may therefore be stated that the disease is not uncommon; and possibly a brief consideration of its causes, character and treatment will prove of some value to the general practitioner.

The subjects may be infants at the breast, or older children. It is not restricted to the poor, but may affect the offspring of the rich, or those in comparatively easy circumstances.

In some, the origin of the flow is simply a catarrhal inflammation of the vulva, but more frequently the vagina is also affected, either primarily or secondarily, and therefore the name given as the title of this paper is preferred. The extent to which the vagina is involved could only be ascertained by the use of a speculum, or of retractors; but such examination is impossible in many cases, scarcely advisable in

any, and, if it be required, a Skene's urethral speculum may be employed in some cases. It will frequently be found that the subjects of this affection are not robust, even though there may be no obvious constitutional taint; in many instances they are pale and thin, and there may be elicited by inquiry a history of enlarged cervical glands, or of catarrhal affections of other mucous surfaces than of those now involved.

Probably the mother's attention will be first directed to the disease by finding mucopurulent stains upon the child's underclothing; or, if it be an infant, by observing similar stains upon the diapers, or upon giving the infant its daily bath, the flow may be seen at the vulvar orifice. The child, if old enough to tell its suffering, complains of itching and burning at the vulva; to relieve the former, rubbing the external organs of generation will be employed, a practice which may be the beginning of abominable, injurious and obstinate self-abuse. The inflammation may extend from the nymphæ and the inner surfaces of the greater lips to the external surface, and even to the substance of the greater lips, which then become very much swollen. In some cases, rare, however, an eczematous eruption appears upon the external face of each greater lip, and even extends to the adjacent skin as far as the groins and the upper parts of the thighs. But more frequently a visual examination will show simple excoriation of the parts, and small reddened surfaces upon the vulvar and vaginal entrance. The first condition results from scratching, and the second, possibly, from the irritant discharge, causing a superficial epithelial desquamation. There will also be seen coming from the vulvar orifice a fluid varying in color from a milk-like white to yellow, or even greenish, in consistence from an almost watery character, to the density of thick pus, and in quantity from a few drops to one or two teaspoonfuls, or even more.

Among the commonly alleged causes of the affection is want of cleanliness. But I am sure that in one of the three cases to which reference has been made, there was no such neglect. Self-abuse is also stated to be a cause; and I have recently met with an instance of this kind—the vile practice having been taught a child of eight years, and which no remonstrance, and no punishment could prevent; even when her hands were tied she would gratify the shameless passion with her heel. But let us be charitable, and careful not to attribute in all cases the vulvo-vaginal inflammation if associated with self-abuse to

the latter; for in most cases the relationship ought to be reversed, the onanism being the consequence of the former.

Foreign bodies may be accidentally, spontaneously or purposely introduced into the vagina. Ascarides, for example, passing out of the rectum may enter the vagina. One of the most remarkable instances of a foreign body having caused a vulvo-vaginitis has recently been reported in the *Annales de Gynécologie et d'Obstétrique*, by Professor Rouvier of the Faculty of Medicine, Beirut, Syria. The patient was a girl, seven years old, who had been for some time addicted to onanism, which is very common in Syria. Seven months before the doctor was consulted this girl was amusing herself with a companion of her age, and this companion, in a sudden freak, put the part of the shell of a hazle nut in her vagina. Injuries to the hymen, as in attempted rape, may give rise to the disease. It may have its origin in exposure to cold, if there should be a predisposition to affections of mucous surfaces. All are familiar with the story of an eminent practitioner who found disease of mucous membranes prevalent over others, and regarded the human being as simply a mucous membrane; when he retired from professional work, he remarked, "I have taken my last fee from a mucous membrane." Without being misled by the exaggeration, we all recognize the fact that some individuals are predisposed to mucous fluxes, and let a girl, whether baby or child, have her external genital organs exposed to the action of damp cold, inflammation of the vulvo-vaginal canal, or of a part thereof, may result.

The duration of the disease varies in different subjects, but in general a longer time is required to cure it in a child than in an adult. More frequently, too, in the former constitutional treatment is necessary.

Of course, if it is known that there is a foreign body in the vagina, the first thing in the treatment is its removal. Whether, as asserted by some, thread-worms in the rectum, the worms not passing into the vagina, may cause the disease, is doubtful; but certainly they will aggravate it, and therefore should be gotten rid of by methods too familiar to the profession to need being stated. Another aggravating cause of the disorder is constipation, and of course this should be corrected. Warm hip-baths weakly impregnated with tar soap, or containing two per cent. of carbolic acid, should be used once or twice daily. If the labia are much swelled, a piece of lint dipped in lead water may be interposed. Should these present raw surfaces,

dusting them with iodoform will be useful. Injections of an astringent or alterative character will be required in many cases; one of the simplest of these is borax dissolved in water, three or four grains to the ounce. Corrosive sublimate, or nitrate of silver, will often prove very useful—the one used in the proportion of 1 to 3000; the other, three grains to the ounce of distilled water: the objection to the one is possible accidental poisoning, and to the other the fact of its staining garments or bed clothing with which it may come in contact. Whatever material be the basis of the injection, the latter should be preceded by thorough washing out of the vagina with warm water; and the injection, too, must be warm. There is in some cases a struggle to get these little ones to submit to an injection, but the struggle will be more difficult for the mother or nurse if the attempt is made to inject a cold liquid into the vagina. The child should be lying upon the back, with the hips somewhat elevated, so that the injected fluid may come in contact with the entire vaginal wall, and so that it may be retained for a time. If weakness of action on the part of the mother, combined with wilfulness on the part of the child, prevent or render incomplete the vaginal injections, a partial substitute may be found in free bathing of the vulva with a warm solution of borax. Let the child be recumbent, the hips elevated, and the nurse or mother, separating the labia, squeeze into the opened vulva a stream of the solution, from a sponge saturated with it. But I wish in these cases especially to commend the iodoform pencils first suggested by Pott. A vaginal suppository is made with iodoform, three to six grains, and cocoa butter. It should be about the thickness of an ordinary lead pencil, and introduced into the vagina, one or two being used in the twenty-four hours. Of course, the child must remain lying down for a time after its introduction. In some cases in which injections failed, or were imperfectly used, or could not be employed from the indocility of the child, and the unwillingness of the mother to compel obedience, the results from the suppositories mentioned have been quite satisfactory.

In many cases the administration of a tonic, such as iron, is indicated, and in some cod-liver oil, and in others one of the preparations of arsenic.

—Small-pox is reported to have broken out in Allentown, Pa., four deaths and five new cases being reported from November 26 to December 1.

QUININE AS AN ABORTIFACIENT.

BY NOLAN STEWART, M.D.,

BURDETT, MISSISSIPPI.

The question as to whether or not quinine exhibits an abortifacient action is one which has elicited much discussion, and is one which has not, as yet, been settled. The observations and experiments made by various members of the profession, have yielded conflicting results. I present two cases in support of the view that quinine may justly be classed as an abortifacient:

Case I. On December the 8th, 1886, I was called to see A. A., mulatto, aged 29, well developed and healthy. On my arrival I found her experiencing uterine contractions of considerable violence. I obtained this history. She was the subject of a malarial toxæmia, the paroxysms being of the tertian variety. She had had two paroxysms previous to the present threatened abortion, and had taken of her own accord considerable quinine, though she could not tell the quantity. Upon digital examination I found the os uteri slightly dilated and very patulous. The membranes were not protruding. This was her eighth pregnancy, all the others going to full term, and the labors being perfectly natural and easy. She gave no history of violence, unless washing at the tub may be considered as coming under that category. She had been accustomed to perform such work during her former pregnancies without any untoward results. She did not think she had hurt herself at the tub. The pregnancy had existed for about four months. I succeeded in stopping the contractions of the uterus by giving decided doses of the tincture of opium, and pursuing the usual course in such cases. I enjoined complete rest. By these means the abortion was averted.

I thought that perhaps the quinine had not been the cause of this threatened abortion, and so ordered that it be taken should the chills recur. The malarial paroxysms did recur, and upon the administration of quinine, 20 grs. in 24 hours, the uterine contractions again commenced. She did not send for me, but discontinued the use of the quinine, and repeated the remedies I had formerly prescribed, there being some left from what I had before given her. She followed the directions previously given with the same result, the arrest of uterine contractions. After this the chill continued. I saw her no more, but on hearing of the second threatened abortion, interdicted the

further use of quinine should they recur, and directed her to let me know if she should again suffer from these paroxysms. Although they did continue, she did not advise me of the fact. On the morning of January 11, 1887, her husband came for me saying his wife was about to miscarry, and I learned from him that, contrary to my advice, she had recommenced the use of quinine. On my arrival at her house, I found that a five months foetus had been delivered. The midwife had vainly endeavored to deliver the secundines.

Upon examination I found the difficulty to be due to an hour-glass contraction of the uterus, the firmness of the contraction being increased by the action of the quinine she had taken, and which was now exhibiting its full effect. After much effort, I succeeded in overcoming this contraction and delivering the placenta, which was adherent. There was some hemorrhage, but the uterus contracted nicely, and I gave a full dose of ergot as an additional measure to guard against hemorrhage. After the miscarriage, I repeated the quinine with the result of relieving my patient of the malarial attacks.

It is now ten months since her miscarriage. She is again pregnant, and has followed continuously her occupation, that of a washerwoman, since her recovery. She came to me ten days since, again suffering from malarial attacks. It is needless to say I did not give her quinine, but have controlled the paroxysms by means of arsenic.

Case II.—On April 27, 1887, W. O. applied to me for medicine for his wife. I had been treating him sometime for gonorrhœa, and his wife contracted the disease from him after she became pregnant. She followed my directions closely. On May 7, she was reported as greatly improved, and I sent her more medicine. A few days thereafter her gonorrhœal symptoms were all gone. Two weeks after she quit using the medicine I had given her, she commenced having chills, paroxysms being of the tertian variety. She procured some quinine and commenced its administration. The symptoms of gonorrhœa had entirely disappeared two weeks before she began to take quinine. I knew nothing of her taking quinine, for I should have advised against such a course. After taking the quinine for two days, she began to experience uterine contractions, and then some hemorrhage took place, upon which I was sent for. When I arrived at the house I found that a three months' foetus had been expelled. The flooding had ceased, the uterus firmly contracted, and my patient resting easily.

The above are the details of two cases which are of considerable interest to me, and I hope also to other members of the profession.

Let us first notice some of the physiological actions of quinine. This drug acts as an irritant, a stimulant, a tonic, an antiperiodic, an antipyretic, and as an abortifacient. Eulenburg claims that when brought in contact with a nerve, it will not excite the motor force of the nerve and produce contraction of the muscles which it supplies, but that the drug must be brought directly in contact with the muscle. Hence, he asserts that it is a muscle-irritant, and not a nerve-irritant. One of the properties of muscular tissue is irritability, but very large doses of quinine, toxic doses, lessen the irritability. Quinine certainly produces phenomena through the instrumentality of the nervous system. In small therapeutic doses it produces an acceleration of the pulse rate, which, it is claimed, is due to a paralysis of the inhibitory nerves.

In tonic doses there is an increase in the blood pressure, due to a stimulation of the vaso-motor nerve centres. In large doses, I have noticed a quickening of the cardiac action and a rise in blood pressure temporarily; but, when the full effect of these doses is attained, the blood pressure is greatly lowered and the heart's action depressed. The quickening of the pulse rate has been repeatedly noticed when this drug is given in tonic doses, showing that quinine does exert an influence upon involuntary muscular tissue.

The muscular tissue of the heart is of the striated variety, though it is practically involuntary. The muscular tissue of the uterus is composed of the unstriated variety, and may be acted upon by quinine in the same manner as other involuntary muscular tissue. In tonic or antiperiodic doses, quinine stimulates the nervous centres. In small quantities, quinine stimulates the sympathetic nerves; but, in large doses, or small doses too often repeated, depresses the function of that system. This drug does not always act as an abortifacient for good reasons. When administered, it is to counteract some morbid influence, and its force is expended in this way; and hence does not cause any action in the muscles. I have repeatedly observed this action when administering quinine to counteract a malarial toxæmia: that, in a person so affected, no material influence upon the arterial pressure or heart's action is noticeable until the morbid condition has been almost or entirely overcome. Again, quinine acts as a stimulant

primarily, but over-stimulation results in an exhaustion of vital force; and so large doses of this drug may cause depression of the cardiac action and inertia of the uterus, from the fact that the dose is so large that the stimulant action is too transitory to produce any decided effect upon either the heart or uterus, or in fact upon any involuntary muscle. Uterine actions which might be set up are, so to speak, crushed by the intensity of the action of the drug.

Bartholow, in his *Materia Medica and Therapeutics*, page 174, says: "Very numerous and conflicting statements have been put forth because there is no exact data. The few cases in which uterine action followed the administration of quinine were doubtless due to malarial intoxication or to other causes; and hence the association of uterine action with the effects of quinine was accidental."

Why should he select *malarial* toxæmia as the cause of uterine action, and say that such action being present when the effect of quinine is attained is only accidental? He lays special stress upon "malarial intoxication," because quinine is so universally employed in the treatment of malarial diseases.

Wood, in his work upon *Therapeutics, Materia Medica and Toxicology*, says: "It seems to me incredible, in the face of daily experience, that even the largest doses of quinia are abortifacient in malarial fevers or in health." It is true that quinine is given to women who are pregnant, and they do not miscarry; but there are reasons why it does not produce such a result in all cases.

Drs. Bartholow and Wood both claim that quinine is a valuable stimulant in uterine inertia, and a stimulant to uterine contractions *after* labor has commenced. If it is a stimulant to the uterus after contractions have commenced, why may it not by its action initiate these contractions?

Prof. Wood claims that this action upon the uterus is not through any "specific action of the drug," but that the contractions are induced by the drug "arousing the general nervous forces of the system, or, in other words, by its stimulant action upon the nervous centres controlling such action of the uterus.

If this be the case, quinine must be accorded the credit, for to say that it is not by a *specific* action, but through the instrumentality of the nervous system, is no argument that it does not exert an abortifacient action. Many medicines, upon which we rely as our sheet-anchors in the treatment of certain diseases, exercise a beneficial influence by

virtue of their action upon the nervous system. How could we influence the nervous system so as to produce the desired result, except by the administration of these remedies? Will any one seek to deprive these medicines of the credit of having produced the effects, simply because they do so through the instrumentality of the nervous system? I think not. It matters not whether the effect produced is accomplished by a "specific action of the drug" or by "arousing the general nervous forces." The fact remains that effect is produced by the drug either directly or indirectly.

In this section of our country, the swamp and malaria are, I may say, synonymous terms. Here the decomposing organic matter, the temperature, etc., are especially favorable to the development of the toxic malarial element. Daily we meet with women who are pregnant, and who exhibit the signs of "malarial intoxication." Many have a distinctly established malarial diathesis and yet they go to full term. Abortions are certainly not more frequent here than in other localities. I do believe that malarial toxæmia may cause abortion just as we see an abortion the result of the effect produced by other diseases. I do not think, however, that it shows any *special* tendency towards the production of miscarriages. It is more than probable that many abortions are attributed to malarial and other diseases, whereas quinine, which has been used in the treatment of those diseases, is the true cause. I do not claim that quinine, under all circumstances, tends to produce an abortion. It is given to relieve some pathological condition, and its action is expended in counteracting such, and consequently does not act as an abortifacient. A drug may produce a certain effect through its action upon the nervous system and yet be given in too small a quantity to excite the nervous action, or in too large a quantity, so as to overpower the nervous excitability, and thus in either case defeat an end which might otherwise have been produced.

In the first case it is of course possible that washing at the tub may have excited uterine contractions, but I do not think it at all probable for the following reasons:

First. This woman had been accustomed, in her former pregnancies, to wash at the tub and perform other domestic duties with impunity.

Second. That it can hardly be considered a coincidence that the exertions of washing should have caused the uterine contractions

just at the time when the quinine was producing its full physiological effect.

Third. My patient did not again wash at the tub, or perform any other work; but, notwithstanding this, on two occasions subsequent to the first attack, uterine contractions commenced when the quinine was exhibiting its full effect.

Fourth. That on the two occasions a discontinuance of the quinine, and a resort to the treatment usual in such cases, an abortion was averted.

Fifth. Upon the administration of quinine the third time, the drug was not discontinued when the uterine action commenced, the fœtus having been expelled before I could give anything to prevent the abortion.

These reasons, I think, are sufficient to show that the abortion was not the result of the work which the woman was accustomed to perform when pregnant and when not pregnant.

In regard to the second case:

First. If this abortion had been caused by an extension of the inflammation to the uterus the woman would have suffered from the effects of it. This she has not done, never having had any symptom of uterine inflammation.

Second. If the abortion had occurred as a result of the extension of the inflammation due to the gonorrhœa, the miscarriage would have taken place before the subsidence of *all* inflammatory symptoms.

Third. The abortion did not take place until ten days, or longer, after all injections had been discontinued. So, evidently, injections could not have been the cause.

Fourth. The abortion took place just at the time when the quinine she had been taking was exhibiting its full power.

For these reasons I believe quinine to have been the cause of this abortion.

I never administer quinine to pregnant women now, without taking every precaution to prevent its action as an abortifacient. I believe if physicians will note carefully the effects of quinine, they will find that many abortions attributed to other causes may justly be traced to this drug.

—John W. Brooks, of Detroit, started from Chicago for New York, November 28. In clearing out his valise preparatory to packing it, he threw on the floor some pills taken by him while suffering recently from neuralgia. After Mr. Brooks left his rooms at the Antisdel House, his eighteen months old child found and eat the pills, and died the same evening.

ABDOMINAL SECTION; FOUR CASES.

BY R. S. SUTTON, M.D.,

PITTSBURGH, PA.

Reported by J. H. Williamson, M.D., Pittsburgh, Pa.

The writer of this report was present at each of the following four abdominal sections performed by Dr. R. S. Sutton, of Pittsburgh, Pa. The first operation was performed in one of the suburbs of Allegheny, Pa., and the other three at Dr. Sutton's private hospital in Allegheny, which was closed for repairs and improvement at the time of the first operation.

Case I.—Mrs. —, Grand Rapids, Mich., aged 36 years. History: The patient first menstruated at 13 years. Her menses were regular and painless previous to the birth of her first and only child. She has had no miscarriages. She had fair health, though she was not rugged, until after her confinement. Her labor was a so-called "dry birth," the waters having escaped ten days before. She was delivered with instruments, but she had little trouble subsequently, her physician ceasing attendance in about two weeks, when she left her bed.

The return of her menses was marked by severe dysmenorrhœa. The menstrual periods were regular; but the dysmenorrhœa steadily increased in severity, and there was frequent menorrhagia. She lost flesh, and suffered constantly with sacral pains and general debility.

Four years ago she had a perineal abscess, which was supposed to be caused by riding on horseback over a rough and stony country. The abscess was of moderate size, was evacuated in six weeks, and was followed by an anal fistula.

One year later she had a second abscess, much larger and more severe, which, when evacuated, left a large defect in the tissues. This defect disappeared, but a second anal fistula was formed. The fistulæ persist at this time.

In February, 1887, the patient first noticed a lump in her right side, about as large as a goose egg. May 8, she was suddenly attacked with peritonitis and cellulitis, and was very sick for over two months. During this time the tumor, which had heretofore received very little attention, became more prominent, and her physician's attention was directed to it. A fibroid was diagnosticated by several physicians at the patient's home, and also in Pittsburgh, when she recovered sufficiently to be brought here.

Dr. Sutton saw the case in consultation with Dr. McCready, of Sewickly, Pa., about July 24, 1887. The patient was then very feeble, profoundly anæmic, her pulse and temperature above 100, and she was losing much blood from the uterus. The tumor referred to, lay behind and above the uterus, and both were movable together. There was also much bearing down pain. The indications pointed more directly to a fibroid of the uterus than to ovarian disease. The left ovary could not be felt at this time. Under the use of ergot, viburnum prunifolium, tonics, stimulants, and country air, she improved in every respect until after September 15. Toward the end of September she began to lose ground rapidly. By October 1, she was vomiting incessantly, her pulse was 132, her temperature above normal, and there was pain in the abdomen. On October 2, Drs. McCready and Sutton found a solid tumor behind the uterus, with considerable pain on pressure.

The abdominal features, however, had changed entirely during the ten weeks which had elapsed. The abdomen was now distended, and fluctuation was distinct, and it seemed probable that the tumor was ovarian.

About thirty-six hours after the consultation, in the presence of Drs. McCready, Williamson and others, Dr. Sutton opened the abdomen, and evacuated and removed a large cyst, which was rapidly separated from numerous adhesions. Passing his hand into the pelvis, he found the other ovary as large as an orange and *twisted* on its pedicle. The abdomen was washed out with hot water, a glass drainage tube was inserted, the wound was closed, and the patient was removed to her bed. After recovering from the shock of the operation, she made a speedy recovery.

Case II.—Mrs. —Pittsburgh, Pa. Aged 39 years. History: Patient first menstruated when 13 years of age; and was regular for the first year. During the next two years there was some menstrual irregularity, which subsequently disappeared. She never had dysmenorrhœa. She has one child, 15 years old; and has had no miscarriage. Four years ago she was troubled with cervical catarrh and erosion, which lasted a year. Her general health has always been good. Three years ago she discovered a small lump in her left side, and at the same time suffered with nausea and vomiting, pain under the sternum, and in the region of the lump, and slight feverishness. She was treated at the time for womb-disease, and in about two months had apparently recovered. Six months later, she had a similar, but less severe attack. Her health began to fail during the second year,

after she discovered the lump in her side. She had frequent attacks of nausea, flatulence and pain in the side and back, and was treated for dyspepsia, the tumor in the side receiving no attention. One year ago she was obliged to take to her bed on account of a great aggravation of the symptoms just described.

During this illness, the tumor, which had grown but little, was diagnosticated as ovarian. In July, 1887, it began to grow rapidly, increasing in size for three months, after which it remained stationary until the date of the operation.

The patient was admitted to Dr. Sutton's private hospital November 4, and operated on November 5.

The usual incision revealed a large multilocular cyst, which was rapidly evacuated with a very large trocar. The other ovary was diseased, and both were removed. The abdominal cavity was washed out with hot water, and the wound was closed. The time occupied in opening the abdomen, evacuating the cysts, tying and securing the pedicle, and removing the cysts entirely was four and a half minutes. The patient was on the table only twenty-four minutes. Her recovery was uninterrupted.

Case III.—Mrs. —, Connellsville, Pa., aged 26 years, menstruated first at fourteen years. Her menses were always regular and painless. She has two children, the younger four months old at the date of the operation. Her attention was first directed to her condition by observing that she remained large after her first confinement. She subsequently became pregnant, and was confined at term. She was admitted to the private hospital, November 7, 1887, and was operated on two days later. The usual incision exposed a large parovarian cyst, which was rapidly separated from extensive parietal adhesions, and the pedicle ligatured and divided in five minutes. Persistent hemorrhage from the raw surfaces required the application of solution of iron and protracted pressure. The abdominal cavity was washed out, and a drainage tube was left in the lower end of the wound. Recovery was uninterrupted.

Case IV.—Miss —, Steubenville, Ohio, aged 31 years. The menses appeared at fourteen years; they were always irregular and very painful. Her general health was fair during the menstrual interval. When about twenty-five years of age she was treated for uterine displacement, and some time afterward she had a severe attack of pelvic peritonitis, probably induced by a badly-fitting pessary. Her health has been very poor for

the last five years. She has had excessive dysmenorrhœa, and general debility during the intervals of menstruation. One year ago Dr. Sutton removed her right ovary and tube, and for a time there was great improvement in her condition; subsequently, however, the old symptoms returned. She was admitted to the private hospital, November 9, 1887, and operated on November 17.

The incision was made in the cicatrix of the former one, and was two inches long. The remaining ovary and tube were found glued down to the pelvis by adhesive inflammation. They were torn loose with the ends of the fingers, and drawn through the abdominal incision. Both the ovary and tube were included in the Staffordshire knot, and were then cut away. The pelvic cavity was well washed out, and the wound closed. The time occupied in operating was eighteen minutes. The patient recovered rapidly, her temperature rising but one-half of one degree.

419 Penn Avenue.

DOUBLE UTERUS AND VAGINA COMPLICATING LABOR.

BY E. C. HELM, M.D.,
CHICAGO, ILL.

On Oct. 16, I was called to attend in confinement Mrs. M., 23 years old, a primipara. She had been in labor four hours. The os was about the size of a ten cent piece, and one-half of it was of usual shape and consistence, while the other half was membranous and ill-defined. Even during a pain it did not become rigid. The vaginal passage seemed to be of the usual size, and so a careful examination was made, when I discovered that there was a double vagina. This fact was unknown to the patient, her husband or her mother. The septum was three lines in thickness, and extended from anterior to posterior commissures, and from the vaginal orifice to as high a point as could be reached, and beyond. On examining the other side of the septum, the rest of the cervix was found. The child had been carried on the left side, and the head was presenting on the left side of the septum. A sulcus extended up the front of the body of the uterus, over the fundus, where it was over an inch deep; hence I considered it more than probable that the septum divided the uterus into two complete cavities.

Labor progressed rather slowly until the os was about two inches in diameter, when the septum, becoming tense with every pain,

retarded labor and added to the patient's suffering. Dr. D. T. Nelson was now called in consultation, and with his fingers succeeded in forcing an opening through the septum within the cervix. The pains had considerably thinned this portion of the septum. Labor now advanced with more rapidity, and in an hour the os was fully dilated and the head pressing on the vaginal septum. This was firm and unyielding, so during a pain I divided it with scissors. The hemorrhage did not exceed four ounces, and the advancing head soon checked further bleeding. The case now proceeded rapidly, and the woman was safely delivered of a living child. She made a good recovery, and now the remains of the vaginal septum exist only as a ridge at the commissures.

SOCIETY REPORTS.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Special Meeting Dec. 14, 1887.

The President, Dr. S. WEIR MITCHELL, in the chair.

Address to the Medical Societies of the United States.

On motion, the following address, Concerning the Dangers to which the Country is Exposed by the Ineffectual Methods of Quarantine at its Ports, and in Regard to the Necessity of National Control of Maritime Quarantine, was adopted, and ordered to be printed and sent to the medical societies of the United States:

"The undersigned, a Committee appointed at the meeting of the College of Physicians, held October 5, 1887, 'to consider the present danger of the importation of cholera into this country, and to secure concerted action among the medical societies of the United States in urging upon the State and National authorities the adoption of a uniform and efficient system of quarantine for all exposed ports,' has the honor of submitting herewith to your Society its report, read October 28, 1887, in regard to the quarantine arrangements at the ports of New York, Philadelphia, and Baltimore.

"The Committee points to the condition of affairs therein described as the outcome of the system of independent municipal and State quarantine which prevails at the ports of the United States, and asks your consid-

eration of a brief criticism of the system, and your aid in an organized effort to establish a more satisfactory order of things by placing the management of maritime quarantine in the hands of the General Government.

"In this country, active consideration by legislators of the dangers which threaten the general welfare by the invasion of epidemic diseases through our foreign communications has, in the past, been fitful in the extreme. From 1698 down to the present moment, it has been only when, goaded by the spur of imminent danger or lashed into activity by the fresh memories of disastrous visitations, the people have with a great unanimity urgently and loudly demanded it, that spasmodic efforts to protect the general health have found a reflex in the statute laws. Whilst our statesmen and law-makers have, with more or less wisdom and constancy, by the enactment of national and local laws, guarded the personal liberties and material interests of the citizen, have established more or less adequate regulations for internal trade and foreign commerce, and have performed the public duty of providing a defence against a common enemy, yet thus far they have, with singular neglect, of their own motion failed to make any attempt to provide against the ever-present danger to the general welfare from the ravages of those epidemic diseases which are brought to our shores. The health laws under which we at present live are, as a rule, such only as emergencies have called into existence. Though many of their provisions may have endured beyond the danger which immediately threatened, they have been framed with an eye single to the present need, and with the expectation that an alarmed public sentiment in the threatened locality would materially supplement their incompleteness. They have seldom or never been drafted with a full recognition of the need of adequate and constant protection of the health of the general public. Imperfect and temporizing as the local health laws have been and still are, the spirit which has inspired them has naturally felt the promptings of local interests only, and their inefficient provisions, as a matter of course, have limited their meed of protection to the local interests involved. Moreover, the commercial interests of rival ports, the partisan struggles of opposing political factions, and the heedless parsimony with which money has been doled out for the execution of such health laws as exist, have rendered their vigorous and fearless administration well nigh impossible.

"We are aware that there are among distinguished sanitarians, even in this country, those who more than question the power of any quarantine regulations which could be devised, however intelligently and thoroughly enforced, to protect efficiently the general public against invasions of contagious and infectious diseases, and who are inclined to advocate the policy that the State should rather expend her energies and money in removing local conditions which favor the development of epidemics and make their spread possible. But the only country where such a policy has been pursued with some measure of success is England, after a decade of expenditure of thirty millions of dollars per annum within her compact, small territory, located as it is out of the line of movement of the hordes of infecting emigrants constantly leaving all ports of Europe, and outside of the latitudes which favor the existence of yellow fever. After the United States of America shall have intelligently spent at least an equal sum, namely, three hundred millions of dollars, in the earnest and persistent effort to improve the hygienic surroundings of the homes of a population already nearly twice as great as that of England, and scattered over a territory thirty-four times as extensive, we may then have reached a condition with regard to public health in which it may possibly be wise to abandon maritime quarantine and to rely mainly upon the protection secured by a perfected local hygiene alone. Meanwhile, under present circumstances, recognizing the enormous cost of radically destroying the conditions which foster the development and prevalence of epidemics by thoroughly removing the filth among which they thrive, and fully appreciating the incalculable benefit which would certainly follow such a wise expenditure of hundreds of millions of the public money, we feel convinced that, with respect to the danger which constantly threatens the public health from abroad, there are at this time only two courses between which to choose, namely, a practical abandonment of the general public to a more or less individual and fruitless struggle with the agents of contagion and infection in whatever localities the movements of immigrants may chance to convey them; or an intelligent, constant, earnest and vigorous effort to stop and destroy them at the ports of entry. Whilst it is true that to remove the local conditions which favor the development and spread of contagious and infectious diseases is to lessen greatly their harmfulness, it is none the less unde-

niable that to destroy the infecting agent or contagium, or to prevent its entrance into the country, is, by a single act, to prevent the implantation of the seed and to render the harvest impossible, let the soil be never so fertile. Furthermore, the cost of preparing to wage a successful combat against the entrance and spread of disease among hundreds of scattered villages, towns and cities is infinitely more than that which would be required to place our ports in a nearly perfect state of defence against those diseases which are now subjected to quarantine; and the loss to the public occasioned by a single widespread epidemic of cholera, yellow fever or small-pox is far greater than would be the cost of the proper maintenance for many years of a perfect quarantine establishment at all of our ports.

The hundreds of thousands of European immigrants who annually reach our country after starting from or passing through localities which are infected with contagious disease, frequently in their persons or in their pestiferous clothing and effects carry with them, often as far as their ultimate destination, the active germs of these diseases; and the herding of these immigrants into the miserably ventilated and frightfully unsanitary quarters usually provided for the steerage passengers on steamships, the modern rapidity of ocean travel, and the great facility with which these swarms of people are soon distributed all over our country, combine to multiply the danger to the public health with which, under the laxity of our laws and the unsatisfactory administration of them, this incessant influx constantly menaces the country.

In their enormous number, their poverty, and their squalor, and in their frequent transportation of all sorts of infections and contagions, these immigrants can be likened only to the oriental pilgrims, in whose track pestilence has so frequently followed. It is, indeed, with the extremest rarity that small-pox or cholera has in modern times been introduced into North America by any travellers other than the immigrant class. To take the proper means to guard the ports of entry against the infected persons and baggage of cholera immigrants would probably keep cholera from our midst; to do the same with small-pox immigrants, with the addition of compulsory vaccination and disinfection of personal effects, as an invariable condition precedent to the privilege of landing, would go far toward banishing that scourge from the land; and the importation of scarlet fever, diphtheria, and like diseases might be prevented by similar measures.

The weighty objections urged against maritime quarantine as a means of protecting the public health from the assaults of preventible diseases imported by sea, are only two: First, the alleged failure to keep out these diseases by this means; second, the alleged injury to maritime trade.

In our opinion the first objection finds a complete answer and explanation in the grossly imperfect state and the maladministration of the the quarantine defences, as shown in the accompanying report; yet it may be truthfully affirmed that the quarantine at the port of New York, in its establishment and administration, is one of the best, in many respects, that will at present be found anywhere in the world. It seems to us, therefore, absurd to argue against the capabilities of a thoroughly equipped maritime quarantine, strictly administered, from the historical failures of those establishments which, with respect to plant, equipment, and direction, have been obviously deficient in the essential requirements of a modern quarantine.

The second objection is always a serious one for a people extensively engaged in maritime trade. But it is met, we think, by a due consideration, in the light of modern knowledge, of the wide and essential difference between the requirements for the proper treatment respectively of the ship's cargo and of the ship's inhabitants. It is the ship's inhabitants, with their personal effects, who almost invariably introduce the infectious germs into the country; the merchandise rarely or never conveys the contagion. Indeed, so far as cholera, small-pox, and scarlet fever are concerned, it is only cargoes of rags that may be looked upon with suspicion as possibly capable of transporting the germs of disease from Europe to America. With this possible exception it is not only unnecessary, but there is absolutely no excuse in the treatment of ships with these diseases aboard to detain the cargoes in quarantine for a prolonged period. With adequate facilities at hand, the proper disinfection of the ship need not require her detention or that of the cargo longer than twenty-four hours, an impediment to trade too insignificant to be taken into account when the paramount interests of the public health are considered.

With reference to the detention at quarantine of those of the ship's inhabitants who are well, it need be prolonged but little beyond the period of incubation of the particular disease against which the quarantine is directed. This detention the traveling and immigrant classes alone suffer, the com-

mercial interests of the general public being undisturbed. In the great majority of instances, it is among the immigrants only that actual cases of disease exist; but when we consider the advantages which the immigrant is about to receive, the necessary detention is but a small sacrifice for him to make for the benefit of the people among whom he seeks a home.

In view of the foregoing considerations, the committee would bespeak your earnest attention to the following propositions:

A. The present methods of independent quarantine provided and regulated by seaboard states or cities are essentially defective and inefficient for the exclusion from the United States of the diseases against which quarantine is directed.

The truth embodied in this statement is abundantly established by the report of the committee in regard to the three ports it inspected. It is fully borne out in regard to the other quarantine stations between the St. Lawrence River and the Rio Grande, by the elaborate official report of Dr. John H. Rauch, Secretary of the Illinois State Board of Health, to that body in 1886.

The defects of local quarantine stations arrange themselves in two principal groups: 1. Inadequacy of establishment. 2. Faults of administration.

1. With regard to the establishment—which term is here used to include the accommodations for the temporary housing and care of immigrants and travelers not sick, adequate hospital accommodations for the sick, appliances for disinfection and the necessary medical, nurse, police, and other attendants for the care of both of these groups of individuals—only four of the many stations upon the Atlantic and Gulf coast may lay claim to anything like adequate provision. These are Grosse Isle quarantine station, on the St. Lawrence River, below Quebec; the Boston quarantine station, on Galop's Island; that in the New York harbor, and those in the mouth of the Mississippi River, below New Orleans.

Of these four, it may be said, first, that the very excellent establishment at Grosse Isle is practically useless as a safeguard against the importation of disease, in view of the fact stated in the report of Dr. Rauch, that during the quarantine season up to October 9, 1885, only thirty-two vessels out of a total of four hundred and twenty arrivals, had stopped at this station for examination: second, that no mention is made in Dr. Rauch's description of the quarantine

station at Boston of any provision for the housing and care of travelers and immigrants not sick; third, that in the last named particular, as well as in several other respects, the quarantine station at New York, hitherto regarded as fully adequate to the requirements of that great port of entry, shows serious defects. According to the official description by Dr. Joseph Holt, President of the State Board of Health of Louisiana, it would appear that the quarantine station at the mouth of the Mississippi is, in respect of establishment, fully up to the requirements of modern science. Of the intervening stations it is scarcely necessary to speak. Certainly, as regards the prevention of cholera, and to a less extent also of yellow fever, the greater number of them constitute quarantine stations simply in name.

2. When we come to consider faults of administration, it is obvious that it is impossible to discover their nature or extent during times of quarantine inactivity: that is to say, during those fortunately more or less prolonged periods in which the absence of disease upon incoming ships narrows the duties of the quarantine officials down to the simple inspection necessary to establish that fact. We have, therefore, at present no criterion by which to judge of the efficiency of the quarantine administration at the greater number of the stations. The fact already mentioned with reference to the quarantine station at Grosse Isle, that during the quarantine season of 1885, up to October 9th, only thirty-two vessels out of the total four hundred and twenty were examined, indicates defects in administration at that station so glaring as to require no further comment.

Faults of administration equally serious, although of a different kind, are shown by the accompanying report of the committee to have recently existed at the quarantine station in the lower bay of New York harbor, at a time when cholera actually existed in the hospital, and was from day to day finding new victims among more than five hundred Italian immigrants detained at the quarantine of observation on Hoffman Island. It is only necessary to emphasize this statement by calling attention to the following facts, brought to light by the investigations of the committee: first, the absence of resident medical officers, both at the hospital on Swinburne Island and at the quarantine of detention on Hoffman Island; second, the absence of anything like an adequate sanitary police force on the latter

island; third, the absence of any effort to separate the well, detained on Hoffman Island, into small groups, and of any proper daily systematic inspection, such as would enable the authorities promptly to discover and isolate new cases of cholera; fourth, the unreasonable detention for a period of nearly two months of more than five hundred immigrants not sick, under circumstances of great hardship, exposure, and deprivation,—a fact which, in view of the present state of knowledge in regard to the nature and mode of transmission of the infecting principle of cholera, in itself bears overwhelming testimony to culpable maladministration; and this was the situation after cholera had continued to prevail in countries the ports of which were in constant, direct communication with New York, for a period of four years, and after the entire public press of the United States had persistently called attention to the ever present danger of its reaching our shores.

B. It is impossible adequately to protect the public health of the country against the importation of epidemic diseases by independent local maritime quarantine establishments.

1. The history of epidemic diseases in this country serves to establish the truth of this proposition. Every epidemic of cholera, typhus or yellow fever, and several important epidemics of small-pox have been directly imported, despite existing quarantine regulations.

2. There is always great difficulty in obtaining sufficient appropriations of public money to defray the expenses of the necessary quarantine establishments and their proper maintenance. It is only possible during periods of threatened invasion to procure the considerable sums of money necessary for these purposes; whilst in the interim the money expended is greatly inadequate, though large amounts are constantly required.

3. Rival political and commercial interests are inimical to the perfect quarantine protection of the general public by independent and local means.

The port of New York, through which three-fourths of the imports and immigration enter the country, is in the following peculiar situation with respect to the relations of local health boards: By the health laws of the State and of the municipality of New York, the principal quarantine officer is a member *ex-officio* of the municipal Board of Health of the city of New York and of the State Board of Health, and he is also a mem-

ber of the Quarantine Commission. Neither the State nor the municipal boards have, therefore, a voice in the control of quarantine. Each of these three bodies consists of a very limited number of members, and each is also entirely independent of any supervision or control by the others. Not only does this anomalous independence exist in accordance with the provisions of law, but there is undoubted evidence of an indisposition of the city Board of Health to inquire in any manner into the management of quarantine at the port, which is not officially under its care.

In a letter dated November 4, 1887, replying to an official communication from the Mayor of New York, making inquiries concerning the dangers to which that city was exposed by reason of the existence of cholera at the quarantine station of the port, and the means of preventing its spread to the city, the President of the municipal Board of Health, after detailing the provisions which had been made for the prompt isolation and treatment of cases of cholera which might develop in the city, explicitly denies official knowledge of the condition of affairs at the quarantine, and further states that he would regard it as unbecoming for him to discuss it; this, notwithstanding the fact that the quarantine officer is a member of that same Board.

4. The last statement illustrates one of the most serious dangers to which the general public is exposed through local maritime quarantine organizations; namely, the possibility of bodies of immigrants with infected baggage being transferred directly from the quarantine station to distant inland communities by rapid railroad journeys, without any prolonged sojourn, or without any adequate inspection or precautions being taken by the authorities of the seaboard cities through which they pass. In point of fact this danger was realized in regard to cholera in 1873, when epidemic outbreaks of that disease occurred in Ohio, Minnesota, and Dakota, which were "caused by cholera poison packed up, in the household effects of emigrants, in Holland, Sweden, and Russia, respectively. These emigrants sailed from healthy ports, in healthy vessels, and were subjected to the usual sanitary requirements of the period. They passed through New York and the intermediate territory without injury to the public health; but when their infected goods were unpacked in the interior of the continent, they liberated the poison which gave rise to the local outbreaks." (Report of Dr. Rauch).

5. It is but natural that municipal organizations should, in looking after their own interests, pay little regard to the welfare of distant communities.

In this connection may be noted the indisposition and failure on the part of local quarantine officers to notify the authorities interested of the arrival of emigrants from infected localities. Notwithstanding the frequent paramount interest of inland communities in the efficiency of the establishment and administration of quarantine at the seaboard, the local authorities of the latter frequently evince an unreasonable jealousy of any sort of investigation or suggestion looking to the general welfare.

6. In the absence of any general regulation or supervision, local quarantine measures must, in the nature of things, be exercised with varying degrees of efficiency; the most complete establishment and perfect administration at a few ports might, therefore, fail to protect the country if defective or inadequate measures of quarantine were practised elsewhere.

C. A national system of maritime quarantine is necessary.

1. It is only by this means that the necessary protection against the importation of epidemic diseases in all our ports can be continuously secured.

2. It is the only practical means by which uniformity of establishment and administration, regard being had to the modifications made necessary by difference of latitude and other circumstances, can be assured. Such necessary uniformity can be obtained by no other arrangement, for the reason that the National Government is alone able to defray the expense of complete quarantine establishments at every port according to the requirement of each, and without regard to the revenue derived from the shipping of any.

3. The benefits of quarantine inure to the welfare of the whole country; therefore, it is just that money should be as freely expended when necessary at one port as at another, without respect to their relative commercial importance. It is manifestly unfair that the seaboard cities and states should, as at present, be obliged to bear the entire expense of quarantine establishments designed to protect the inhabitants of every region of the vast territory of the United States.

4. A national quarantine, properly administered and conducted by trained officials accustomed to deal with contagious and infectious diseases, would tend to prevent panic, to allay undue anxiety, and to favor a reasonable sense of security.

5. Experience has shown that much needless alarm, as well as preventable danger, arises upon the appearance of an unfamiliar epidemic disease at quarantine stations; as when cholera has shown itself at New Orleans or New York, or yellow fever at Philadelphia or Boston. A national quarantine would do away with the necessity for vexatious temporary interstate quarantines.

6. A national quarantine system, directed in such a manner as fully to meet the requirements of existing sanitary knowledge, would not adversely disturb any commercial interest. It would, on the contrary, do away with many of the embarrassments incident to maladministration of existing local regulations. For example, the healthy passengers of the Italian steamship "Alesia" were detained at quarantine in New York harbor for a period of fifty-eight days, while under an efficient system uninfluenced by needless fears, those of them who were free from disease could have been safely liberated in ten days at furthest.

7. A national quarantine would not necessarily supersede any existing arrangements regarded as expedient by local authorities. It should be conducted wholly without cost to shipping, and would thus work no additional pecuniary hardship, even if the present fees were to be still exacted.

8. The ability of the National Government, by an existing act of Congress, to come to the aid of local quarantine authorities in answer to the appeal of the Executive of any State in time of grave danger, implies a function of very narrow scope and uncertain application. Appeals of this kind are apt to be deferred until the emergency is extreme, and the aid obtained from the Government is, therefore, likely to be rendered too late to accomplish its purpose.

D. A national organization would secure advantages not attainable by independent local quarantine establishments however complete.

1. Suitably arranged and commodious buildings, provided with necessary furniture and appliances at all ports.

2. An efficient corps of trained officials and assistants always on duty.

3. The practicability of the concentration of force, money, and attention at any threatened port without loss of time.

4. Officials under control of the National Government, and free from local political and commercial influences.

5. The objects of quarantine would be furthered by full and reliable consular reports and sanitary inspection of emigrants at ports

of embarkation, functions properly belonging to officials of the General Government.

The organization of a national maritime quarantine system in the United States would require the enactment of laws by which—

1. The whole matter would be placed under an appropriate department of the General Government.

2. A central bureau of control established at Washington.

3. A sufficient corps of medical officers and assistants, with nurses, sanitary police, laundrymen, engineers, and officers and crews for boarding tugs, organized at every station. Among the requirements for the medical service should be a speaking knowledge of at least two modern languages besides English. The establishment of a school and laboratories for sanitary instruction and research in connection with this service would be an advantage. In addition to the men on duty at the respective stations, there should be a sufficient number of medical and other officials fully trained in quarantine duties and familiar with contagious diseases, unattached and available for immediate auxiliary service at any threatened port.

4. The erection of necessary hospital, and other buildings, wharves, disinfecting apparatus, wash-houses, latrines, etc., in suitable localities, when possible upon islands at or near the entrances to harbors, and at some distance from the main channel.

5. These stations must be organized and fully equipped at every port of entry of the coast, in such a way as to meet the requirements of each port in the measure of its commerce and immigration, and the especial diseases to which it is most exposed.

6. The cost of the establishment and maintenance of the National maritime quarantine should be provided for by appropriation from the National treasury, and not from fees exacted from vessels.

SUMMARY.—Under the present system of local and independent maritime quarantine, the necessary quarters for the detention of large numbers of immigrants arriving in a suspected vessel, are either entirely wanting, or, if at hand, are deficient in equipment or administration or both. It is possible, however, that one port well governed and rich from prosperous commerce, may make up these deficiencies; yet what would this avail even to that community itself, if a neighboring port, only a few hours distant by rail, failed to exclude epidemic diseases. The front door might be doubly barred and bolted, but the enemy would find an easy passage through the defenceless rear.

This want of uniformity in the quarantine defences along our coast must necessarily exist when different authorities supply the money for maintaining the several stations, and the purse of one port is longer than that of its neighbor. Another money difficulty is found when the appropriation for the same station comes, as it may, from the coffers of both city and State; possible difference of opinion in the municipal council and the State legislature is likely to endanger the sufficiency or change the direction of the funds to be expended. In any case, the danger to a single port of entry, or even to a single State, is by no means the same as that which threatens the country at large, and communities are not likely to make a larger expenditure than is needed for their own defence. As an illustration of a difference in the conditions of danger which may exist between a port of entry and the interior of the country, may be mentioned the passage of immigrants with infected baggage. The immigrants may come from a healthy port and in a healthy ship, and with the poison securely imprisoned in their baggage, will pass through the port of entry with perfect safety to its inhabitants; the danger will begin in that far interior where the baggage is opened. It is of no interest to that port to have the baggage disinfected, and it is carried on to some uncertain place unhindered to do its fatal work. And here may be pointed out the rather peculiar position in which America finds itself, in attracting to its shores hordes of immigrants from the older countries. There is in municipalities little disposition to spend more even than is called for to satisfy immediate wants; remote necessities are seldom provided for. A quarantine that is not always in use, is not always ready for use. It is only when danger is at its gates, and when, perhaps, it is too late for protection, that a city wakes up to its defenceless state. Municipalities are selfish, and knowing that with the trader quarantine is not a favorite institution, and that it is his tendency to sail into that port where the quarantine is most lax, they are assailed with a sore temptation to wink at the neglect of proper precautions, if, by so doing, they may circumvent a possible commercial rival.

In the opinion of the committee the difficulties mentioned can only be overcome by the adoption of a maritime quarantine under the control of the National Government.

The danger from immigrants would not be entirely banished, however, though the quarantine of the coast of the United States were perfect; for the way through the British

provinces would still be open to these travelers. In the absence of efficient quarantine inspection in the St. Lawrence River, the attempt thoroughly to protect ourselves from importations of epidemics, would necessitate the doubtful and difficult expedient of a land quarantine. The more efficient plan would be to have the same precautions taken at the ports in the British provinces as should be practiced at those in the United States, but this course could only be assured through treaty, which our local authorities are not competent to make.

It appears that our Canadian neighbors have already evinced their desire for uniform quarantine laws for the two governments. The Provincial Board of Health of Montreal, recognizing a community of interest in the question of maritime quarantine, have deemed the presence of the Canadian Fish Commissioners in Washington opportune for the adoption of resolutions requesting them to urge upon the American authorities "the necessity of establishing uniform quarantine regulations for both countries." In connection with an efficient system of national quarantine, a harmony in the provisions of law in the United States and in Canada seems indispensable for the full protection of our extensive northern frontier, and our national government should be strongly urged to respond actively to the expressed wishes of the Canadian authorities relating to such an important matter of common interest.

In conclusion, the College of Physicians of Philadelphia, through its committee, earnestly asks your prompt consideration of the matters herein set forth, and your active coöperation in an organized effort to obtain this winter such national legislation as will efficiently and with reasonable security protect the public health, not only from the danger of the importation of cholera and yellow fever while they are epidemic in countries with which the ports of the United States are in communication, but also from the at present almost incessant conveyance into the interior of the contagion of scarlet and small-pox by emigrants. The disappearance of cholera from the quarantine station at New York, without the development of the disease anywhere in the country should be regarded as a fortuitous occurrence, but at the same time a serious warning. This country has never yet escaped an epidemic of cholera when it has visited Europe. Sooner or later, the disease has invariably been introduced and has spread more or less widely throughout the country. We should, therefore, profit by the cold season, during which we are

comparatively safe from the ravages of two of the most dreaded of our imported epidemic diseases, to prepare against a possible, and, as some believe, even a probable, advent of cholera with the return of warm weather. We should use the present opportunity to arouse public sentiment and our national legislators to the necessity of wise, deliberate, far-reaching, and prompt action in behalf of the general welfare, by the establishment all along our coast of a thoroughly equipped and efficiently directed maritime quarantine.

In the case that your Society determine to coöperate in securing the ends in view, we would respectfully suggest that you at once notify the committee of the fact, and, without delay, authorize a member of your body (whose name and post-office address should accompany the notification) to confer with the committee either by correspondence or in person, for the purpose of deciding upon the details of a bill to be introduced in Congress early in the present session.

If your coöperation be agreed upon, we would further suggest that, as a body and as individuals, you assist in influencing legislation by the following means:

1. The passage of formal resolutions recognizing the necessity of National control of maritime quarantine, and urgently recommending the matter upon the consideration of your representatives in Congress.

2. Strenuous efforts to enlist popular sentiment in support of such legislation.

3. The enlistment of the influence of the local medical and secular press.

Finally, in view of the necessity of inaugurating, at the earliest moment possible, the effort to secure the proposed legislation, we would earnestly request prompt action on the part of your Society and early notification thereof.

J. C. WILSON, *Chairman.*

E. O. SHAKESPEARE,

R. A. CLEEMAN.

Communications on this subject may be addressed to

DR. J. C. WILSON,
College of Physicians, Philadelphia.

—Dr. Heneage Gibbes, who is Lecturer on Physiology and Normal and Morbid Histology at the Westminster Hospital, London, has been appointed Professor of Pathology at the University of Michigan. Dr. Gibbes formed, with Dr. Klein, the English commission to investigate cholera in India.

REPORTS OF CLINICS.

BELLEVUE HOSPITAL, NEW YORK.

MEDICAL CLINIC—PROF. A. A. SMITH.

Aneurism of the Aorta.

On November 17, Prof. A. A. Smith presented two patients to the class. A patient with an aneurism about the junction of the ascending with the transverse portion of the aorta. The patient was a truckman, aged twenty-five years, who had been perfectly well until eight weeks ago, when he was struck upon the head by an elevator. Soon after this accident his throat began to get sore, and the soreness, as he described it, gradually increased in severity, and he became hoarse. He is now, said Prof. Smith, unable to swallow, not on account of the soreness of his throat, but of his inability "to get it down." Inquiry revealed the fact that he is able to swallow milk. The difficulty in swallowing came on *before* the hoarseness set in. He gives a history of syphilis. Upon auscultation, a decided diminution of the respiratory murmur on the right side is noticed; and an examination of the heart reveals a loud systolic murmur. The left radial pulse is stronger than the right.

This case is interesting from the fact that a young man should so rapidly develop a syphilitic disease of the blood vessels leading to aneurism. The prognosis is grave. An aneurism developing with such rapidity is likely to end fatally before long. As regards treatment, we shall give him good nourishment, and continue the "mixed treatment" of iodide of potash and mercury.

Dilatation of the Stomach.

The patient felt well up to six weeks ago, when he complained of a painful point in the right hypochondriac region. Upon inquiry it is ascertained that he has had vomiting also. Three weeks later he had cramps in the stomach, which lasted nearly the whole night, and were relieved by a hypodermic injection of morphine. He has had no fever, no chill, nor any chilly sensations. He has lost flesh, and indulges moderately in stimulants. He presents a great prominence in the epigastric and umbilical regions.

The causes of dilatation of the stomach are various. Weakened conditions of the muscular layers, paralysis of the same, obstruction of the duodenum, and, especially, obstruction of the pylorus, give rise to this condition; and the result is the production of fermentative changes, evinced by tympan-

itic distension and vomiting. This affection is very frequently confounded with other diseases, and, unless with the vomiting, emaciation and variable appetite, we can find an induration of the pylorus, it will be hard to diagnose the trouble exactly. Physical examination reveals in this case tympanitic resonance on percussion. In doubtful cases you might give the patient a few mouthfuls of water to swallow, and while applying the

ear over the distended organ, shake him, when a spashing sound will be heard. As regards the treatment: foods in small quantities, frequently repeated, of the lightest kind, such as beef-tea, digested meat, etc., should be given. Foods that are likely to undergo fermentation should be given very sparingly, or avoided as much as possible. Washing out the stomach with alkaline solutions is also recommended.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Actinomycosis which was Cured.

At a meeting of the Society of Physicians of Vienna, on November 4, 1887, Ullmann presented a man, who, for a year had begun to grow thin and to suffer from loss of appetite and pain in passing his water. Fever and great turbidity of the urine, which contained pus, were present. Subsequently, a tumor formed at the lower part of the abdomen, which was repeatedly opened, and much pus evacuated from the abscess which had developed. Upon his admission to Professor Albert's clinic, there was found a tumor of bony character, occupying the right hypochondrium. A wound in the neighborhood of Poupart's ligament, as well as the bluish-violet coloration of the skin, induced Ullmann to diagnose actinomycosis. A microscopic examination of the pus, which contained the characteristic granules, confirmed the diagnosis.

Ullmann thinks, with reference to the above described symptoms which preceded the disease, that the case was one of actinomycosis of the bladder.

The patient was operated on in Albert's clinic, and recovered in four weeks. Examination of the pus, which the author has carried out in several cases of actinomycosis, has induced him to think that suppuration in this disease is not occasioned by the actinomyces, but is produced by other micro-organisms (staphylococci).—*Deutsche Medizinische Zeitung*, November 14, 1887.

Hypnotism in Court.

The London *Chronicle* gives a strange account of a trial in Solax, a village in Malaga, Spain, of some religious fanatics, of strange practices. They originally went naked, like Adam and Eve before their fall, but the authorities interposed. Since then they have inflicted wounds upon themselves

in imitation of the Crucifixion, and burned all their goods, believing that a higher power would provide food. A strange part of the affair is, that when put on trial they were hypnotized in court by a medical specialist, and proved good subjects. It is alleged that on being ordered to perspire they broke out in a profuse perspiration. Others were pricked with pins, but gave no sign of pain. This is the first time such a scene has been witnessed in a court of justice in Spain. It is difficult to see the object. Probably the result of the trial will be a nominal punishment.—*Philada. Evening Telegraph*, Dec. 1, 1887.

Operation for Nephritic Colic; Recovery.

At the Sixtieth Congress of German Naturalists and Physicians, in September, 1887, Von Bergmann reported the case of a man who had had attacks of nephritic colic for eight or ten years. Residence at Carlsbad and at Vichy relieved him for a long time of his attacks of pain. Then a fresh attack occurred, the pain starting from the left kidney, and being followed by the expulsion of a calculus. The pain ceased after a while, and was succeeded by anuria. It was found, by passing the catheter, that the bladder was empty. The anuria persisted for six days, and during this time the patient perspired profusely, the skin being oedematous. In other respects the patient did not suffer great inconvenience. On the sixth day, he was seized with vomiting. Von Bergmann's diagnosis was occlusion of the pelvis of the left kidney or the left ureter by calculus, coincident with functional suppression of urine on the part of the right kidney, caused by lesions of long standing. He proceeded to do nephrotomy, and having found the pelvis of the left kidney clear, located the calculus in the ureter, about two and a half inches from its origin. It was then removed by dilating the ureter with forceps.—*Gazette Médicale de Paris*, November 5, 1887.

A Case of Tetanoid Constriction of the Uterus.

In a paper read before the Gynæcological and Obstetrical Society of Baltimore, November 8th, 1887, Dr. H. M. Wilson describes the case of a woman of about 24 years of age, whom he saw first four years ago, just after her marriage. She was of fine physique and healthy appearance. Her trouble at that time was uterine neuralgia. Each catamenia was attended by distressing pains, lasting from one to two days. Stenosis was suspected and an examination advised, but she declined this, giving as a reason her great sensitiveness to pain, and her nervous dread of it. Nothing of special note occurred during the two years following, except a small subcutaneous abscess in the right iliac fossa, which was lanced and soon healed. This reappeared in a smaller form—about the size of an almond—two months ago. At the end of three years, she became pregnant. Her gestation was accomplished without special distress, except on several occasions after moderate exercise she had slight attacks of syncope—the last, about four days prior to her confinement. Five days before labor, whilst in bed, and without any exertion on her part, her water was discharged. Dr. Wilson was called to see her on Wednesday, October 19, and found her bright and cheery, free of headache, with pains described as sharp, at intervals of about ten minutes. Upon examination the soft parts were found to be in much better condition than had been feared. The bowels were twice moved; the kidneys acted freely. The os was entirely closed. Upon his return in two hours the os had opened to the size of a dime; the edges were soft and thin, and, as far as could be made out, the head presented in the right occipito-anterior plane. The patient now commenced to complain of nausea to the extent of emesis, which was frequently but not inordinately repeated. The further progress was slow, but did not seem to require either bleeding or medicine. At 5.50 in the afternoon, he deemed the os sufficiently dilatable to admit a careful application of Simpson's forceps, the head being within easy reach. No difficulty was encountered in their adjustment, but in the effort to deliver no advance could be made. Thinking the funis might be abnormally short or tightly wrapped about the neck, he substituted the Tarnier instrument. He could cause the head to appear at the vulva so as to be seen, but it instantly would disengage itself from the blades and fly back to its former position. While he dispatched a messenger for Prof. Milten-

berger, Dr. Wilson for the first time observed the pallor of the patient, and, putting his finger on her pulse, found it a mere thread. Instantly suspending the anæsthetic, he administered brandy freely by the mouth and requested Dr. Pole, who was quickly at hand, to kindly assist him in repeated hypodermics of brandy. The patient never rallied, and died within thirty minutes. The fœtus was dead, but, seeking for some solution of this terrible and inexplicable result, Dr. Miltenberger effected the post-mortem delivery. Upon introducing his hand he found a band embracing the shoulders, which, to use his own words, "gave the impression of a band of steel." It was only after a prolonged and most persistent effort, and that coupled with the occasional fear that the trial would have to be abandoned, that version was finally accomplished.

Chloroform was used occasionally, in small quantities, for probably an hour, just at the completion of a pain, "to blunt its edge," as the patient expressed it, but not carried to its full effect; indeed more as a placebo. This was thought proper on account of the patient's highly sensitive organisation, and to quiet, as far as possible, her urgent demands for relief. When instruments were used chloroform was inhaled freely, but, as before stated, instantly abandoned upon the appearance of dangerous symptoms. She came from under its influence speedily, asking questions, complaining of the strength of the brandy, demanding water, requesting to be fanned, etc.; her intellect remaining unclouded to the last.

The author does not believe that chloroform was the cause of death, and says that he cannot recall an absolutely certain death from its use in obstetrical practice. If such result has happened, it is an exception to the general rule. In this case the patient passed from its influence quickly, and, so far as he could observe, entirely. As for the forceps, they were applied without difficulty and used with discretion. In nothing did the manipulation differ from their constant and ordinary use.

A Case of Poisoning with Cocaine.

H. Schnyder, in the *Correspondenz-Blatt f. Schw. Aertze*, No. 15, 1887, reports a case of cocaine poisoning, which occurred under the following circumstances: A young apothecary, of somewhat nervous habit, was advised by a friend to take one-third of a grain of cocaine, repeated in three-quarters of an hour, for violent headache. As he lost

the muscular sense in his extremities, and developed oppression in breathing, he took as an antidote to the poison twenty drops of tincture of *nux vomica*. After about half an hour, his extremities, which were icy cold, began to tremble violently. His pupils were immovable, moderately dilated, pulse thready and one hundred and fifty to the minute. The action of the heart was strikingly feeble, and in addition there was violent excitement, and at times delirium. Strong coffee was administered, warmth applied to the extremities, and chloroform sprinkled on cotton and inhaled.

In an hour respiration became freer, pulse fuller and one hundred and twenty to the minute. On account of the violent headache, cold applications were made to the head and a mustard plaster to the chest. After four hours had elapsed, the pulse sank to eighty beats, but sleep was not obtained for some time.

Cysticercus in the Anterior Chamber of the Eye.

Dr. Robinowitsch reports in the *Westrick Ophthalmologie*, III., p. 196, the case of a woman, thirty-five years old, who had had an iritis a year before. He found, in the anterior chamber of her right eye, a hemispherical, grayish swelling, of the size of a pea, which concealed the lower third of the pupil. At the lower part of the tumor was noticed a small continuation, which was capable of changing its size; and at times there could be seen wave-like contractions of the cyst, upon which it somewhat changed its position. The iris and the vitreous were unaltered; vision was $\frac{3}{80}$. The author removed the tumor by an incision through the cornea, and established the diagnosis by a microscopic examination.

Castration in Epilepsy.

In the *Berliner klin. Wochenschr.*, No. 3, 1887, J. Schramm reports two cases in which he performed castration for epilepsy. In the first case the ovaries were healthy, and the operation was done on account of the coincidence between the epileptic attacks and menstruation; in the second case the ovaries were cystic, but the connection between the epileptic seizures and menstruation was not so positive. Immediately after the operation repeated convulsions occurred, but subsequently ceased entirely. In the first case there was no return of the disease within eighteen months; in the second within a year after the operation.

A Method of Antisepsis for the Urethra and Bladder.

At the meeting of the Academy of Medicine of Paris, October 29, 1887, M. Lavaux read a paper upon a method of antisepsis for the urethra and bladder, and its application to the treatment of strictures of the urethra. The following is a summary of his conclusions, as contained in the *Progrès Médical*, November 12, 1887: 1. Continuous *lavage* of the anterior part of the urethra and intravesical injections without a sound, constitute a simple and harmless method of accomplishing complete antisepsis of the urethra and bladder. 2. This method is applicable to the treatment of most strictures of the urethra. 3. Thanks to this complete antisepsis and the antiphlogistic action of hot injections into the bladder without a sound, complications due to rapid dilatation of the urethra are now very uncommon. 4. In the treatment of simple strictures which are easily dilated, rapid dilatation ought to be substituted for slow temporary dilatation, which is of but little value. 5. Intra-vesical injections made without a sound are sufficient to maintain the calibre of the dilated urethra. 6. Indications for the performance of internal urethrotomy become extremely restricted. 7. This method of treatment by securing antisepsis of the bladder and urethra ought to render divulsion and internal urethrotomy much less serious operations.

The Value of Strophanthus in Diseases of the Heart.

Dr. C. W. Suckling, professor of therapeutics in Queen's College, Birmingham, writes to the *British Med. Journal*, November 19, 1887, that he has been using strophanthus for several months at the Birmingham Workhouse Infirmary, and with little success. At first he thought that it might be due to a badly prepared tincture; and to some extent this was the case. In all his cases hitherto he has found that, though tincture of strophanthus has done some good, yet the substitution of an equal quantity of tincture of digitalis has been attended with marked benefit, and he has ceased to prescribe strophanthus where it is important to obtain immediate improvement. He has also found that vomiting occurs from strophanthus quite as frequently as from digitalis; and concludes that strophanthus, at any rate in the dose and preparation in vogue, is decidedly inferior to digitalis in its action in heart affections.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.25
Reporter and Pocket Record, - - -	6.00
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets,

P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 10,250 copies.

IMPURITIES IN ICE.

Early in the year 1887, DR. PRUDDEN, of New York, published a paper in the *Medical Record* (March 26 and April 2), on the subject of Impurities in Ice, which attracted a great deal of attention. The substance of this paper was a description of the varieties and numbers of micro-organisms which he found by experiment to be capable of resisting the temperature of ice, and of preserving in it the power of development and multiplication. Especially striking was the discovery that the bacillus of typhoid fever survived freezing for more than 103 days; although repeated freezing and thawing caused them to disappear in three or four days. Certain kinds of ice were found to contain more bacteria than others, the most prolific being snow-ice and ice containing bubbles. Clear ice was much freer from them.

The same subject is discussed in a more general way by DR. LEWIS BALCH in an interesting paper in the seventh annual

report of the State Board of Health of New York. In this paper Dr. Balch cites indisputable proofs that ice may contain impurities, not only theoretically but also actually, dangerous to health. In 1875, an epidemic of bowel disorder occurred at Rye Beach, which, on investigation by that well-known sanitarian, Dr. A. H. Nichols, of Boston, was found to be due to the use of ice cut from a shallow pond containing a large quantity of decomposing organic matter. In 1878, Dr. C. Smart, of the U. S. Army, traced the origin of mountain fever to the snow-water of the Rocky Mountains. In 1879, an epidemic of dysentery occurred in the village of Washington, Conn., and was found to be limited to persons using ice from a small and polluted stream. In 1880, the Connecticut State Board of Health reported several cases of inflammation of the bowels, due to the use of sewage-polluted ice. In 1882, the same Board reported a case of typhoid fever in a person who had a private ice supply, cut from a pond which had received the dejecta of a typhoid fever patient. In 1884, Prof. Leidy reported to the Academy of Natural Sciences, of Philadelphia, that he had found a number of living worms and animalcule in a specimen of ice used for cooling drinking water. In 1885, a destructive epidemic of typhoid fever occurred in Plymouth, Pa., and was traced to the dejecta of a typhoid fever patient, which froze in the snow, and afterwards thawed out and passed into the water supply of the town.

The facts just cited, and the result of investigations made by a number of competent observers, leave little doubt that the ingestion of ice is probably more dangerous than that of water which has not been frozen. It is possible that some of the effects which have heretofore been attributed to drinking-water may have rather been due to ice used to cool it with. In this city, for example, where the water-supply has been thoroughly studied and much discussed, no investigation, so far as we know, has ever led to the detection of well-recognized disease germs in the water; and it may be that

cases of disease charged against the Schuylkill water may have been caused by bacteria preserved in ice brought from a great distance.

However this may be, it is well for those to whom the health of the community is entrusted to be aware of the fact that there is good reason to believe that ice may contain the sources of disease. We do not believe that ice is a very important factor in the propagation of disease, or that what is known of its power of preserving the life of bacteria justifies any great alarm. But, in an age when disease germs are supposed by intelligent men to play such an important rôle, it would appear wise to warn the public that the use of ice may not be altogether free from danger.

In some European cities—Vienna, for example, where most of the ice is obtained from the muddy Danube—the inhabitants never think of putting ice into water to cool it, but accomplish this by putting vessels of water into ice. Such a plan we should think advisable in our own country, wherever it is feasible; especially as some of the bacteriological investigations, made in connection with ice, indicate that to reduce the temperature of water to the freezing point by an extreme application of cold will reduce the vitality of any germs which it may contain, without running the risk of adding to it others which may be present in a state of suspended animation in the ice itself.

OVER-EXCITEMENT OF CHILDREN.

It was one of the sayings of Goethe that whatever has proved valuable in the past will come up again for consideration, and this idea is illustrated in the fact that our attention has recently been called for a second time to a paper on what the author calls Emotional Prodigality, by DR. C. FAYETTE TAYLOR, of New York. This paper was published in the *Dental Cosmos*, July, 1879, and it contains some truths which deserve to be brought again to the notice of thinking men and women.

Dr. Taylor's experience has made him fa-

miliar with the conditions in which many children live who suffer with wasting diseases, and especially diseases of the spinal column and joints; and it is his deliberate opinion that many of these diseases are largely fostered by undue mental and psychical stimulus. This is a fact which is, in a general way, well recognized by physicians, and to some extent appreciated by intelligent parents; but, as Dr. Taylor says, this idea is too indefinitely held to produce much good. To be of real service it must be made more precise. Many hygienists are just now trying to secure a better regulation of the studies of children, and a greater amount of wholesome recreation for them; and the dangers of too much study are not altogether ignored. But the damaging effect of the competitions and rivalries at school, or even of the ambition of a child to learn for the love of knowledge, is more clearly shown and more vigorously denounced by Dr. Taylor than by any other writer with whose work we are familiar.

Again, he points out a source of danger which we believe is not half appreciated by the community, namely, the soliciting of demonstrations of affection with which almost all little children, and especially vivacious children, are so often tormented. It is to this form of excitement that the significant term, "Emotional prodigality," is especially applicable. The effect of such kissing and hugging as most children get cannot but be injurious to the health of their minds, and Dr. Taylor has seen instances in which it was disastrous to their very bodies. As he justly remarks, these solicitations of emotion, or of a pretense of it, are exhibitions of selfishness on the part of those who make them. Parents or grand-parents, and more particularly female relatives, may be blind to this fact; but it is a fact to which their attention ought to be called; and they ought to be taught that very serious consequences may result to the little ones whom they sincerely love if they will not restrain the temptation to indulge their selfish desire to kiss and be kissed. Emotional prodigality of a dangerous sort is sometimes provoked when demonstrations of affection are lavished upon and solicited

from older children; and even in the earliest years emotional prodigality may give rise to serious disorders of the mind or body.

This is a somewhat homely subject, but one which, as we have already remarked, is of great importance, and worthy of being brought to the attention of physicians, who have it in their power to warn and instruct those who have the care of children, and who often sin against them unwittingly.

AN APPEAL FOR A NATIONAL QUARANTINE LAW.

The College of Physicians of Philadelphia appointed a special committee, Oct. 5, 1887, "to consider the present danger of the importation of cholera into this country, and to secure concerted action among the medical societies of the United States in urging upon the State and National authorities the adoption of a uniform and efficient system of quarantine for all exposed ports." This committee has just made its report to the College of Physicians in the form of an "Address to the Medical Societies of the United States," which has been approved and adopted by the College, and is now issued under its sanction.

The substance of this address, which is published in another part of the *REPORTER*, is that the present methods of quarantine, resting upon local authority and depending upon local support, are not sufficient to protect the interior of the country from the invasion of contagious and pestilential diseases. And all the members of the profession, especially organized medical societies, are urged to lend their influence to induce Congress to pass a proper Quarantine Law to be enforced by the National authority, and to be supported by Government funds. The need for a uniform plan of protecting the whole of the United States from the importation of disease will appear to any one who will study the subject; and it is no less clear that such a plan can be properly carried out only by the National Government.

We, therefore, heartily commend to the thoughtful consideration of our readers the address of the College of Physicians, and hope that they will take an active interest in

securing for it the endorsement of the societies to which they belong.

HYDROPHOBIA.

In the last number of the *REPORTER* we published a clinical lecture, by Prof. Whittaker, on a case of so-called hydrophobia. We have had access to some sources of information about this case other than that supplied by Prof. Whittaker's lecture, and have come to the conclusion that it was one of what is known as *lyssophobia*. The evidence shows that it is a pure assumption to suppose that the man was bitten by a dog at all; the fact being that he himself for awhile believed that the little wound in his lip was caused by a blow from the dog's nose, driving the lip against a tooth. The man seems to have done well enough until he had an attack of dyspnoea while leaning over a tub of scalding water. At this time an officious neighbor informed him that this was the way in which hydrophobia began, and at once he became alarmed, and passed through stages perfectly familiar to those who have made a special study of hydrophobia, and finally died. What share in his death is to be attributed to the treatment he received, it would be hard to say. But we warn our readers that they need never expect to cure a patient supposed to have hydrophobia, if they watch him very closely, expose him at a public clinic, offer him water, inject morphine and chloral into him; and, above all, if they add the administration of curare to these measures. A careful study of the literature of hydrophobia shows that morphia, chloral and curare—drugs recommended in most of the books—are useless and probably dangerous, given, as they usually are, in cases called hydrophobia.

These remarks are prompted by the fact that such teaching as is contained in the lecture of Prof. Whittaker, is, in our opinion, calculated to do much harm, if it be allowed to pass unchallenged.

In another part of the number of the *REPORTER* will be found the result of our investigation of a case of so-called hydrophobia, reported recently from Chicago—a case

which was published all over the country as a remarkable instance of the disorder. As will be seen by our report of it, it was not hydrophobia at all; but no daily paper which dilated on its horrors has published a correction of its mistake.

The last case in New York—with the points of which we cannot burden our readers—was as clear a case of delirium tremens as one would want; and yet hospital physicians there regarded it as one of hydrophobia, treating it with brandy, chloral, digitalis, and curare; confining the man in a straight-jacket, and having several men to hold him. The patient died, as might have been expected; but there is no evidence whatever that he had hydrophobia.

Let our readers take note that hydrophobia does not seem able to bear the face of skepticism; that it disappears where it is not talked about; that it flourishes where it is cultivated, as in France, and does not exist among savage and enlightened peoples. And let them sift carefully any case which seems like hydrophobia, as to its history and symptoms; let them eschew violence of act or of medication in treating it, and see what the result will be.

ILL-NATURED CRITICISM.

We regret to observe that the *Medical Press and Circular*, of London, has published, Nov. 16, 1887, with the heading, "A Gem from the American Congress," a paper which it says came into the hands of its representative at Washington. This paper, as published, contains many errors in spelling and in grammar, and the object of the *Medical Press and Circular* in printing it seems to be to hold up to public contempt the writer, and the Congress at Washington. A careful reading of the paper discloses the fact that its author had had under treatment a case of obstinate neuralgia, and desired the advice of the medical men attending the Congress as to the best way in which to treat it. The difficulties of the case are described somewhat inelegantly; but the whole paper is deserving of serious consideration, and not to be mocked at; and there is no

warrant, in the circumstances connected with it, for the way in which it is made to figure as a disgrace to the medical profession in America.

We hope that the regret we feel at this act of the *Medical Press and Circular* will be shared by it on second thought; and that it will make what reparation it can for an unkindness which we trust was the result of want of reflection rather than a want of kindly disposition toward the medical men of this country.

PLUGGING.

"Plugging" is a term used in Scotland for the process known in most countries as "tamponing." At a recent meeting of the Glasgow Obstetrical and Gynæcological Society, Dr. Tindal asked what Dr. Pollock would do in a case like this: "A lady out walking is suddenly seized with hemorrhage. She faints and becomes almost pulseless. She is plugged, etc." This term sounds ludicrous and almost gross to those who are not accustomed to it; and we think it not only less elegant, but also less exact than the one with which we are more familiar.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

A COMPLETE HAND-BOOK OF TREATMENT. By WILLIAM AITKEN, M.D. (Edin.), F.R.S., etc. Edited, with notes and additions, by A. D. Rockwell, A.M., M.D., etc. 8vo, pp. 444. New York: E. B. Treat, 1887.

It is hardly necessary to say much of the general merits of this book, which is composed of the chapters on treatment taken from the seventh edition of Aitken's Encyclopædic work on the practice of medicine.

Wherein the notes and additions of the American editor consist, it is not easy to see from the book itself; and it is to be feared that the way in which they are incorporated will not be appreciated very highly by Dr. Aitken. We are sorry also to find no evidence that this book has been published in this country with due regard to the rights of authorship and publication, which the much needed international copyright law would enforce. Furthermore, it contains marks of carelessness, like the repeated use of "ce" for "æ," and of an endeavor to make the book cheap at the expense of good paper, good printing and good binding, which does not commend itself to our approval, and which we fear will not gratify the original author, if he ever sees a copy of it.

HYGIENIC PHYSIOLOGY, WITH SPECIAL REFERENCE TO THE USE OF ALCOHOLIC DRINKS AND NARCOTICS. PATH-FINDER PHYSIOLOGY NO. 3. By JOEL DORMAN STEELE, Ph.D. 8vo, pp. xii, 276. New York and Chicago: A. S. Barnes & Company. Price, \$1.25.

This book is an amplification of the two others of the same series which we have already reviewed, and is intended for older children. It has the defect and the merits which we pointed out in speaking of them. The same strained effort is made to prove that alcohol is an unmitigated curse to mankind as is made in its predecessors; and the same attempt to instil the principles of physiology and hygiene. We are glad to be able to speak highly of most of the teachings of this book, which is handsomely printed and well illustrated. It contains a good chapter on "Hints About the Sick-room," and on the treatment of emergencies.

MINER'S NEW INDEX REVIEW FOR STUDENTS AND PROFESSIONAL MEN, Pocket size. From 18... to 18... Published by JOEL A. MINER, Ann Arbor, Mich. Price, \$1.25.

This is an exceedingly well arranged book, with pages ruled and printed in such a way that it will be easy to find any reference recorded in it. It is the kind of a book which every medical man might well have in his pocket or on his table, so that he can jot down at once any matter which he may wish to refer to afterward.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The *Sacramento Medical Times* announces that, with the January number, which begins the second volume, it will be enlarged to 48 octavo pages, and undergo other improvements. We are glad to note these and other evidences of prosperity in a journal which has secured our respect for the way in which it is conducted, and which has our hearty good wishes for the future.

—The holiday number of *Wide-Awake* is a very handsome and interesting number; but its suitability for children is ruined, in our opinion, by a characteristic story by H. Rider Haggard, illustrated by a dreadful picture of two lions in desperate combat, and with their faces are carefully turned toward the spectator, as if they were posing to be photographed. It is a pity to spoil what otherwise would be a very good thing by putting such a story and such a picture in it.

—At the last meeting of the Medical Society of the County of Kings, N. Y., the society authorized the publication of a monthly medical journal to be known as the *Brooklyn Medical Journal*. This journal is to be edited by five members of the society, appointed by, and under the control of, the council. It will contain the transactions of each meeting, together with the papers read and the discussions thereon. It is expected that it will also contain the transactions and papers of several other societies, and items of general and local medical interest. The first number will be issued January 1, 1888. The price is to be \$2.00 a year.

CORRESPONDENCE.

Intercostal Neuralgia Cured with Antipyrin.

EDS. MED. AND SURG. REPORTER:

Sirs:—I was called, on Nov. 26, to see Samuel Crawford, aged 50, who was suffering with severe intercostal neuralgia. He had been bedfast for three days, and was getting worse. He lay in one position, flat on his back, and dare not take a deep inspiration or move his body in the least. The pains, he said, "felt as if a bomb exploded in his side and tore it out." During an explosion the sweat ran off his face. There was no fever, but the heart's action was feeble and accelerated. The patient lives on the edge of a large, wet meadow, where malarial diseases are common. He told me that two years ago he had an attack of sciatica, which lasted six weeks. I never saw so bad a case of intercostal neuralgia before. I ordered for him half a grain of morphine every two hours until his pain was relieved, and six grains of quinine every four hours. I saw him the second time after sixteen hours, and his symptoms were not improved. I then ordered a teaspoonful of "Tongaline" every hour until relieved; then every two hours.

The next day the pain was gone; but the following morning he was worse than he had been at all. I found him in great pain, and learned that he had had diarrhoea for over twelve hours. It occurred to me that the Tongaline had purged the patient, and on account of the frequent evacuations had ceased to be absorbed, thus failing to keep control of the disease. I now gave a hypodermic injection of morphine and prescribed ten grains each of bismuth subnit. and tannic acid, every two hours, until the diarrhoea was controlled. I ordered, also, ten grains of antipyrin in hot water, three times a day.

I saw the patient again the following morning, and found him comfortable, but weak. I ordered antipyrin in ten grain doses, thrice during the day, and for the next two days twice daily. He has had no pain to speak of since the evening of the first day when he took the antipyrin.

Yours truly,

C. H. SHIVERS, M.D.

Haddonfield, N. J., Dec. 6, 1887.

Pathological and Biological Work.

EDS. MED. AND SURG. REPORTER:

Sirs:—I beg to call your attention to the fact that this Laboratory has been established for original research into the nature and

causes of the contagious and infectious diseases of animal life. It has a general working room, supplied with all the necessary instruments and books of reference, a cultivating room, an autopsy building, and a room for raising and keeping the small animals generally used in experimentation.

It is my desire to make the Laboratory as useful to the country as possible; hence its advantages are offered to Boards of Health, Live Stock Commissioners, and Educational Institutions that may desire to have some *attaché* instructed in these especial branches. This Laboratory offers better advantages for such work than any other in the country, as we are constantly busied in investigations upon a number of diseases, and can give those desiring it an opportunity of proceeding at once in such work. We will supply workers with animals and everything necessary, except a microscope, slides, and covering glasses. In order to cover the expense of material used, a fee of \$100 will be charged. The time of attendance will not be limited; but as our rooms were originally intended for personal use, we can accommodate but two persons at once. No one but graduated physicians or veterinarians will be admitted, and such persons must have the endorsements of a Board of Health, a Live Stock Commission, or the President of a University or College with which they are connected.

Yours truly,

FRANK S. BILLINGS, M.D., *Director.*
 Patho-Biological Laboratory,
 State University of Nebraska,
 Lincoln, Neb., Nov. 28, 1887.

Spurious Hydrophobia.

[On November 22, it was reported from Chicago that a man named Bruno Mueller, of that city, was suffering with hydrophobia, and that his case presented some features which made it peculiarly interesting.

In June last, it is said, Mueller and his ten years old son were in a saloon in the neighborhood of his residence. The boy began playing with a small cur which had strayed into the place. The dog bit the lad in the hand, and while attempting to rescue his son from the animal's attacks the father was also bitten. Six weeks later the boy died, and his physicians had no hesitation in pronouncing the case one of well-defined hydrophobia. Last Saturday the father was stricken down with the same disease. On November 22, four prominent physicians were in attendance, and friends of Mueller were constantly with him to care for him in

his spasms. Mr. Mueller realized his condition, and, during lucid intervals, disposed of his property.

In order to get at the facts of this case, we wrote to our correspondent in Chicago to investigate it for us, and received the following reply]:

EDS. MED. AND SURG. REPORTER:

Sirs:—Answering yours of recent date, I have carefully investigated the Mueller hydrophobia case, and there is nothing of special interest in it. It is true the boy was bitten by a supposed rabid dog, and died a short time afterward; but the animal, as is usually the case, was killed immediately afterward, which certainly buried the evidence as to whether the dog was mad or not. It is reasonable to presume, however, that the animal *was* rabid, on account of the speedy, fatal termination. That the father is now stricken down with the same disease is false. The dog's teeth simply penetrated the father's clothing, and did not leave even a perceptible impress upon the skin. The case, I find, was much exaggerated by the newspapers, and the fact of the father being sick for one day only led to the publication of the item which you sent me. I had hoped to glean information of more than ordinary interest for you in this case, but it amounts to comparatively nothing.

Yours truly,

WM. WHITFORD, M.D.
 146 Warren Ave., Chicago, Ill., Dec. 1,
 1887.

EDS. MED. AND SURG. REPORTER:

Sirs:—In the REPORTER of December 3, in your very valuable article on the Treatment of Typhoid Fever, you mention antifebrine. Will you kindly say how you prescribe it? I can find no satisfactory solvent. It requires too much alcohol to dissolve it. This has been my trouble with antifebrine.

May I suggest that you ask your contributors to be more explicit in some of their statements? For instance: in the REPORTER for Dec. 3, Dr. John Aulde speaks of cannabis Indica as being valuable in certain cases, in half drop doses; but fails to say what preparation he means. The fluid extract is probably meant; but, for accuracy, it should have been stated. I do not mean this for idle criticism. Correspondents would make their articles more valuable by stating more explicitly how, and in what doses, they use drugs, especially the newer ones.

This note is not designed for publication.

I am anxious, though, to know about antifebrine.
Yours truly, F. H. VAN EATON.
Clear Water, Kansas, Dec. 10, 1887.

[The letter of Dr. Van Eaton, though not intended for publication, deserves this, for the sake of our readers.

His questions may be answered as follows:
1. The best way to give antifebrine is to use the powder in wafers or mingled with some syrup, like sarsaparilla. If it is to be given in solution, there is no better solvent than alcohol, or a tincture. 2. Exactness and clearness are graces which few writers possess; and, with the best endeavor to attain them, even editors do not always succeed. So we will take to ourselves, and recommend to our contributors the practical and kindly criticism of our present correspondent.—EDS. REPORTER.]

Treatment of Hemorrhoids.

EDS. MED. AND SURG. REPORTER:

Sirs:—Could I ask for information, through the columns of the REPORTER, regarding the use of carbolic acid injections in hemorrhoids? What are the details of procedure, and what has experience taught as to the efficacy of the treatment in this common and troublesome affection?

Yours truly, SUBSCRIBER.
McConnellsburg, Pa., Dec. 8, 1887.

[This subject is well described in "The Diagnosis and Treatment of Hæmorrhoids," by Charles B. Kelsey, M.D., published by Geo. S. Davis, Detroit, Mich.; price, 25 cents. It is also thoroughly discussed in "Rectal and Anal Surgery," by Edmund Andrews, M.D., published by W. T. Keener, Chicago, of which we made a review in the REPORTER, Nov. 26, 1887.—EDS. REPORTER.]

—The proposition of Health Officer Patterson, to send Philadelphia lepers to Louisiana, has not been well received in that State. President Holt, of the New Orleans Board of Health, says: We are amiable to a fault, but we are not so inconsiderate of ourselves as to permit the perpetration of a high-handed outrage of the kind proposed by Health Officer Patterson, of Philadelphia. We have no settlement for lepers, and perhaps very few more lepers in Louisiana than there are in Pennsylvania; and, even if we had such a settlement, we would not permit Philadelphia or any other place to unload their lepers upon us in the abrupt and impudent manner proposed by Health Officer Patterson.

NOTES AND COMMENTS.

Three Cases of Resection of the Intestine.

In a paper read before the Detroit Medical and Library Association, and reprinted from the *Medical Age*, September 26, 1887, Dr. H. O. Walker, of Detroit, Mich., reports three cases of resection of a portion of the alimentary canal. The first case was that of a baker, 48 years old, who always enjoyed good health until two or three years ago, when his appetite began to fail with no appreciable loss of flesh. This condition continued up to about a year and a half ago, when he observed a sense of weight in the lower part of the sacrum, and an occasional dull and aching pain in the lower portion of the rectum. In July, 1877, he had an attack of diarrhoea, with severe, acute pain at every movement of the bowels. He also passed blood and pus at times. These attacks of diarrhoea became more frequent until it became a permanent affair, necessitating the use of the water closet as often as twenty times in the twenty-four hours. He was treated all this time, by various physicians, for piles. In May, 1878, Dr. Walker, with the patient's physician, Dr. J. H. Carstens, who suspected syphilitic or malignant disease, made a thorough examination of the patient and found several rounded tumors, varying in size from a filbert to a pea, around the verge of the anus, simulating very much old external hemorrhoids with no ulcerated surface. These were also found within the rectum, but were more or less ulcerated above the internal sphincter. The disease extended up anteriorly three inches, and posteriorly about four inches, with considerable of a constriction of the bowel, admitting with difficulty a Sims' speculum. The diagnosis was encephaloid cancer, which was verified by the microscope.

On Aug. 10, 1878, Dr. Walker placed the patient in the lithotomy position, when an examination revealed a decided progress of the disease since the last examination; so that it extended in front about four inches, and behind fully five inches. The anterior wall of the rectum was quite movable, while the posterior wall was apparently adherent to the coccyx. The external incisions were elliptical, extending below to the tip of the coccyx, and about an inch above the verge of the anus, entirely encircling the diseased tissue. After cutting above the sphincters, he enucleated the remaining portions with his fingers and the aid of blunt-pointed, curved scissors. Being satisfied that all of

the disease was enucleated and pulled down, an incision was made through the healthy part of the gut, and, by means of a silver suture, made fast at the medium line above; then cutting off the remainder of the diseased portion, other sutures were introduced, stitching the healthy rectum to the integument. As it was necessary to remove a V-shaped piece from the posterior wall of the gut, no sutures were used at that point. All disease adhering to the lower part of coccyx was thoroughly removed with a pair of curved scissors. A perforated drainage-tube was introduced behind the sutures and above the rectum, the ends coming out at the lower part of the external cut.

There was but little hemorrhage, and only the middle sacral artery had to be ligated. Time of operation, one hour and ten minutes. All instruments, sponges, ligatures, etc., used during the operation, were taken from carbolyzed water. The wound was thoroughly washed out with carbolyzed water, and compresses of lint (carbolyzed) were applied with a T-bandage.

The patient passed a comfortable night, with slight nausea, the result of the anæsthetic. On the next day, the wound was thoroughly irrigated with warm carbolyzed water at intervals of every three to six hours. The temperature at 4 P.M. was $102\frac{1}{2}^{\circ}$, pulse 90.

On the tenth day succeeding the operation, some of the sutures pulled out and were removed. About the fifteenth day all the sutures were removed, the gut receding about an inch, with a healthy granulating surface everywhere apparent. The patient continued to gradually improve, and six weeks from the date of operation he was allowed to leave the hospital with the wound nearly healed, and able to care for himself.

Dr. Walker made a careful examination, November 1, 1878, and could not discover any evidence of return of the disease. A circular cicatricial band of half an inch in width, just within the anal orifice, served the purpose very satisfactorily of a sphincter. He had very little trouble in controlling the bowel except when the fæces were lax, and as a matter of precaution he wore a small compress of oakum, kept in place with a T-bandage. He was then working at his old trade, namely, that of baker, performing his duties as well as he ever did. His general health was good, and his weight had increased twenty odd pounds. Dr. Walker saw him at intervals until October, 1879, when he came to him complaining of pain in the region of the stomach with frequent vomiting. He was not

seen again, but Dr. Walker was informed that he died some months afterward with cancer of the stomach.

The second case was that of a Canadian Frenchman, twenty-seven years old, who came under Dr. Walker's care, February 26, 1880, at St. Mary's Hospital. When first seen he presented an extremely forlorn condition, with the following history: Six days previous, while calling upon his sweetheart, his hernia, right (direct) inguinal, which had existed for four years, and was readily kept in place by a truss, came down, and, owing to the situation, he did not reduce it. On attempting reduction several hours afterwards, he found it impossible. When brought into the amphitheatre his temperature was $103\frac{1}{2}^{\circ}$, pulse 130, and he was delirious; so much so that it was impossible to get from him at the time an intelligent history of his case. In the right groin there was an immense black swelling extending well up the abdominal wall and down into the scrotum. It was subsequently learned, that for two or three days previous to his entering the hospital he had vomited stercoraceous matter. Using ether as an anæsthetic, Dr. Walker proceeded to operate, first drawing off with an aspirator over a pint of fetid serous fluid. He made no attempt at reduction by manipulation, but proceeded at once by an incision of several inches in length to lay open the parts. On reaching the intestine, it gave way, discharging a quantity of fecal matter. The whole of the cæcal convexity was sphacelated, and was removed. After cutting the constriction and removing all necrosed tissue in the vicinity, which was considerable, he stitched to the abdominal wound the ends of the colon and ileum, leaving the ilio-cæcal valve in view at the opening of the wound, through which the fecal discharges afterward took place.

The after-treatment consisted in constant irrigation of the wound with carbolyzed water, by means of a rubber siphon. Dr. Walker provided for keeping the patient dry by means of a large sheet of oiled silk, with an opening made through it large enough to expose the wound, and by fastening it near its edges with sticking salve. By this means he succeeded in keeping the wound clean. The recovery was tedious, and the patient became very much emaciated, although he received large quantities of nourishment in the way of milk, eggs, and beef. It will be remembered that the function of the alimentary canal was entirely cut off below the ilio-cæcal valve.

On May 1, 1880, he attempted to close the opening, by uniting the ends of the

colon and ileum, but failed. He then resorted to the method of the late Dr. Wm. A. Byrd, of Quincy, Illinois, and described by him in the *Philadelphia Medical and Surgical Reporter* for October 25, 1879, which consists, first, in destroying the spur with a steel wire enterotome shaped like a pair of tongs, with the blades fenestrated. He introduced one blade of the enterotome into the colon, and the other into the ileum for about three inches, holding them in apposition by strong rubber bands. On the fourth day following the introduction of the enterotome there was a free evacuation from the rectum—this being the first that had occurred since his entrance to the hospital. On the sixth day he removed the enterotome. From this time on the evacuations were all from the rectum, with exception of a small quantity occasionally from the ilio-cæcal opening. On June 2, he was partially successful in closing the opening. The failure to do so entirely was due to the large amount of sloughing in the vicinity. The mucous membrane which exuded was destroyed by means of the thermo-cautery, and, finally, the whole thing cicatrized. He left the hospital in July, 1880, well and in good health. When heard from, three years ago, he was reported to be performing the work of a farm hand.

In the third case, Mrs. C., aged 32, had a slight femoral hernia that existed for several years. Dr. Walker saw her first with Dr. C. G. Jennings, June 20, 1885. The night before the Dr. had been called and treated her for what he deemed a simple case of diarrhœa and vomiting, no mention having been made to him of a hernia. In the morning, being no better, he made a thorough examination and discovered a slight femoral hernia about the size of a walnut. He made considerable effort to reduce it, but failed. In the afternoon both physicians again attempted reduction (the patient being anæsthetized), but failed. The seriousness of the case was explained to them, and the necessity of surgical interference; but they refused, wishing to wait awhile. Ice was ordered to be applied constantly to the swelling. The next morning they were sent for again, when the family consented to an operation. Cutting down and opening the sac a knuckle of ileum protruded about the size of a walnut; it was partially gangrenous. The constriction was divided and the intestines sufficiently drawn forward to expose the healthy portion.

After excising the gangrenous portion, about an inch and a half in length, Dr. Walker hesitated whether to make an artificial anus or coapt the resected ends with catgut.

Hesitation, he says, undoubtedly, in this case, caused the death of the patient; yet Dr. Walker confesses that his knowledge and practice of antiseptic in this case was bad. He united the divided ends with the continuous suture of catgut and returned the bowel into the abdomen.

The patient seemed to do well for forty-eight hours (the temperature about 100°), when general septic peritonitis set in, and she died on the fourth day after the operation. An autopsy was not permitted.

"Surgeons are not agreed as to the advisability of excising a portion of the rectum for cancer—it is generally condemned. I have been chief assistant at a number of such operations, and they all died within a few days, or as many weeks, although my case might be, according to Dr. Kelsey, classed as a 'literary curiosity.' I shall not hesitate to give my patient the benefit of an operation in this class of cases; for, if the operation does not kill the patient, it certainly does make life more tolerable as long as the patient lives.

The conclusions to be deduced from the report of case No. 2 would be that I did the best that could be done for my patient under the circumstances. Any attempt at union of the resected ends would have been disastrous, owing to the large amount of necrosed tissue. I would have certainly had septic infection that I could not have controlled. I feel confident, that had my antiseptic precautions been perfect in case three, that the result would have been different."

Gonorrhœa in Young Children.

Dr. J. S. Prettyman, Jr., of Milford, Del., in a letter to the *Med. Record*, November 12, 1887, says that on August 25, D. L., nine years old, was sent to him by a physician from a neighboring town to be operated upon for phimosis. Upon examination an acute urethritis with balanitis was discovered, and no operation was performed. He admitted having several times in the previous three weeks attempted sexual intercourse with a colored girl, seventeen years of age. Two days afterward an older brother, aged eleven, came with the same disease, and acknowledged infection from the same source. They were both treated for gonorrhœa and are now entirely well.

On Aug. 15, he visited Miss —, aged nine, the youngest member of a family of excellent social position, and found her with a severe urethritis and vaginitis. She had already been treated three weeks by external applications to the vulva, her physician think-

ing she had a cutaneous disease. Not wishing to humiliate the girl, Dr. Prettyman refrained from interrogating her in regard to the source of infection, but diagnosed gonorrhœa and put her under treatment. At present she micturates without pain and the discharge has entirely ceased. In these cases the physicians had failed to diagnose the disease, because they did not expect to see gonorrhœa in children so young.

Anæmia or Chlorosis of Girls.

At the meeting of the Medical Society of London, on November 14, Sir Andrew Clark read a paper on this subject, which is published in the *Lancet*, November 19, 1887. The author stated that many years ago, when studying the effects produced upon the body by the undue retention of the excretions and of the products of their decomposition, he came to the conclusion that the anæmia or chlorosis of girls was brought about for the most part by fæcal poisoning; and his later experience has given increased probability to this view. The girl who is the subject of this anæmia, while often declaring herself perfectly well, looks extremely ill. She is plump, but pallid; her countenance has a wistful or sad expression; the face is so puffed that its finer lines are effaced. The eyes are large and prominent, the conjunctivæ are white and watery, the pupils dilated, and the eyelids swollen; the lips are full and of a pale purple color. In addition, it is found, on cross-examination, that she suffers from various nervous symptoms and has digestive disturbances, with inadequate or irregular discharges of fæces. The genital disorders of chlorosis may be summed up by saying that the menstrual period is usually regular; that the discharge is scanty, pale and otherwise altered; that sometimes there is amenorrhœa; that on rare occasions the menstrual flow becomes excessive and irregular; and that almost always there is a leucorrhœal discharge. He further said that the condition was one which was not confined to any particular class of society; it occurred in the underfed and the overfed, in the rich and the poor alike. The alleged special causes which have been put forward with respect to the causation of anæmia by Virchow, Germain Sée and others, are all inadequate to account for it. In speaking of his own opinion as to the cause of the disease, he said that girls at puberty began to think more about their personal appearance; they ceased to take the same active exercise as before; they pinched in their waists and developed a self-consciousness in all their

acts which led to their being very shy about going to the closet. He quoted the researches on the subject of the formation of alkaloids in the intestines, and urged that everything pointed to a toxic absorption. In collateral proof of his assertion he instanced the almost invariable success which attended the administration of aperient mixtures, which unloaded the bowels and restored things to their normal condition. He discussed the dietetic and medicinal treatment of such cases in detail, and pointed out that aperients were even more essential than ferruginous preparations. In patients who had been treated without success for months a cure was rapidly effected if these principles were borne in mind. To maintain the cure it was of course essential to prevent the recurrence of the condition of things which had given rise to it.

The following is a prescription which he very commonly uses for this disorder:

R Ferri sulph. gr. xxiv
Magnesie sulph. ʒvj
Acid. sulph. arom. f ʒj
Tinct. zingiberis f ʒij
Inf. gent. co. *vel*,
Inf. quassie. f ʒviij

M. Sig.—One-sixth part twice daily, about eleven and six.

In the discussion which followed the reading of his paper, in answer to the objection that if fæcal accumulation caused this form of anæmia it ought to be as frequent in boys as in girls, Sir Andrew Clark said that it was not accumulation of fæces in the rectum which caused the disease, but accumulation of fæces in the colon.

Fluid Extract of Pichi in Vesical Catarrh.

Dr. H. S. Dalamere, of Lubec, Me., in a letter to the *Med. Record*, referring to the use of pichi in the treatment of catarrh of the bladder, relates the following case:

A. B—, aged twenty-eight, had been suffering for two years from vesical catarrh. He had had gonorrhœa, but a No. 21 (French) bougie passed without difficulty, causing, however, considerable vesical tenesmus. When called to see him Dr. Dalamere found that he was passing urine every hour during the day, and four or five times during the night. The urine was alkaline, ropy, and ammoniacal, and the microscope revealed pus. The usual remedies prescribed in country practice, such as buchu, uva ursi, etc., were used, but without benefit. The bladder was then washed out by means of the double-channel catheter, with the effect of relieving the patient slightly. The least exposure, however, aggravated all

the symptoms and caused as much suffering as ever. After about a year and a half of constant treatment, with no other result than to keep the disease at bay, fluid extract of pichi was tried. After the patient had taken it a few days he expressed himself as feeling better, only getting up twice during the night. But, while obliged to wait for a fresh supply, the patient grew worse, being obliged to get up three or four times during the night. As soon as the drug arrived it was given him, in doses of twenty drops four times a day, which dose was subsequently increased to thirty drops. In a few weeks the patient was so much better that washing out of the bladder was abandoned, and at the time of the report he was at work, the urine being clear, free from mucus and pus, and with no ammoniacal odor. He slept well and did not have to get up more than once during the night. Although he recently suffered from a severe cold, the bladder trouble did not return. The man's general appearance is healthy, appetite good, and he seems well.

News Items.

—An epidemic of measles has broken out in Lille, France, and is reported to be making great ravages.

—The Newark Medical and Surgical Society has been organized by twenty physicians for the purpose of discussing scientific, medical and surgical subjects.

—Dr. M. Allen Starr is to succeed Dr. E. C. Seguin as Clinical Professor of Diseases of the Mind and Nervous System, at the College of Physicians and Surgeons, of New York.

—Dr. Asa Gray, the eminent botanist, lies ill at his home in Cambridge, suffering from a stroke of apoplexy, from which it is feared he will not recover. Dr. Gray is 77 years old.

—Diphtheria of a peculiarly fatal character is prevalent in Montreal, Quebec. In the last week in November there were thirty-two deaths from the disease, and the death-rate shows no signs of decreasing.

—The Department of Public Safety, in Philadelphia, has directed the police in various districts of the city to procure specimens of milk from dairymen, in order that they may be tested by Dr. Cresson, a public analyst.

—Malignant diphtheria has broken out in the Orphan Asylum connected with St. Joseph's Convent, at Marquette, Mich. There were four deaths on December 2, and over

twelve more alarming cases were reported among the children.

—Louis C. Schulmeyer, a druggist who was supposed to have dropped dead from heart disease in a wholesale drug store in Indianapolis, the last week in November, committed suicide by hydrocyanic acid, of which he swallowed nearly an ounce.

—A telegram from Little Rock, Ark., dated December 5, says: Alarming reports continue to come in of the spread of black diphtheria in Clay and adjoining counties. Local physicians are unable to control the disease. There have been over fifty deaths within three weeks.

—Dr. Van Reuterghem is authority for the statement that there are no less than eight different kinds of aconitine in the various European markets, differing from one another to such an extent that some samples are several hundred times more poisonous than others.

—Arsenic is said to have been discovered by Scholvien in many samples of chloroform. Its presence may be accounted for by supposing that arsenic was in the sulphuric acid or the manganese used in the manufacture of the chloride of lime, with which the chloroform had been made.

—Some friends of the late Dr. T. R. Varick are getting up a memorial of his devotion to his profession and long and arduous services at St. Francis' Hospital. The memorial will be in the form of a complete case of surgical instruments and sick-bed appliances, which will be presented to the hospital.

—A Babies' Hospital has been incorporated in New York City, and has purchased a house, and now appeals to the public for support. The statement is made that, out of 10,000 beds in the various New York hospitals, only 27 are devoted exclusively to children under one year of age. This statement cannot be held to mean that 9973 hospital beds in New York are used exclusively for persons over one year of age, and that only 27 babies can be treated in the hospitals of New York at one time. But it certainly justifies an effort to provide a special hospital for infants. As the managers of the new corporation say, infants require a sort of care which is hard to get in a general hospital, and we have no doubt that a hospital for infants especially, under the care of such medical men as are connected with this new enterprise, will prove beneficent to many little sufferers, and provide a valuable place for instruction in the treatment of the diseases of infancy and early childhood.

HUMOR.

AS DIRECTED.—Old lady (in drug store to small boy): "What am I to take this medicine in, sonny?" Sonny: "Take it in your mouth, mum."—*New York Sun*.

THE editor of an agricultural paper wrote to one of his subscribers that he would be glad to receive something from his pen. To his surprise, the farmer at once sent him—a pig!

AN emetic was prescribed by a physician to a patient, who replied, "Doctor, there's no use in giving me an emetic. I've tried it twice before, and it won't stay on my stomach."

AS SOON as you forget to pay a man a small sum you owe him, tell him so and he will be satisfied. It is the putting off, and putting off, of such payments, and not telling the man you have forgotten it, that makes him mad.

HYPochondriac: "I am feeling very blue this morning." Doctor: "What's the matter?" "Every time I feel my nose it hurts me." "But you are not obliged to feel your nose." "But how can I tell whether it hurts unless I feel it?"—*From the German*.

"DOCTOR," said a wealthy Boston patient, "I want you to be thorough, and strike at the root of the disease." "I will," said the doctor; and brought his cane down with a smash on a decanter standing on the side-board. It was his last professional visit at that house.

—Dr. Holmes, on being asked when the training of a child should begin, replied: "A hundred years before it is born." Unborn parents should remember this and commence in time. There would be fewer duds and Anarchists in existence 100 years hence."—*Norristown Herald*.

ENTER Irishman (picking up a 6-oz. bottle from counter): "Good marning, yer honor! What would be the price of a bottle this size?" Druggist: "Two-pence; but if you are going to have anything put in it, it will cost one penny." Irishman: "Faith, then, yer honer, shove a cark in."—*Chemist and Druggist*.

ROBINSON—Are you off for a trip, Brown? Brown—Yes, I'm going to take a four-weeks' run over to London, Paris, and some of the German capitals.

Robinson—Business?

Brown—No, health. My physician says my system is all run down, and that I need absolute rest.

AN editor, who does not mind a joke at his own expense, says he went into a drug-store recently and asked for some morphine. The assistant objected to giving it without a prescription. "Why?" asked the editor; "do I look like a man who would kill himself?" "I don't know," said the assistant; "if I looked like you I should be tempted."

REPORTER (to eminent physician)—"Anything new this morning, doctor?"

Eminent Physician—"Oh—um—ah, yes—an operation at the Cheek and Chin Hospital, one of the most wonderful known to science. I took out a man's pericardium, put three stitches in it, and restored it. The patient lived twenty minutes. A most rare and successful case."

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Dec. 11, 1887, to Dec. 17, 1887:

First Lieutenant W. B. Banister, Assistant Surgeon, ordered to proceed at once from Fort Lowell, Ariz., to Fort Wingate, N. M., and report to the Commanding Officer for duty. S. O. 128, Dept. Ariz. Dec. 11, 1887.

First Lieutenant H. S. T. Harris, Assistant Surgeon, ordered from Fort McIntosh to Camp Pens, Colorado, Texas.

First Lieutenant Paul Clendenin, Assistant Surgeon, ordered from Camp Pens, Colorado, Texas, to Fort McIntosh, Texas. S. O. 143, Dept. Texas. Dec. 12, 1887.

First Lieutenant J. M. Cabell, Assistant Surgeon, ordered for duty at Fort Niobrara, Neb. S. O. 286, A. G. O. Dec. 9, 1887.

Changes in the Medical Corps of the Navy, during the week ending Dec. 17, 1887:

Medical Inspector A. Hudson, ordered to the "Trenton."

Medical Inspector N. L. Bates, detached from the "Trenton," and put on waiting orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Dec. 19, 1887:

R. D. Murray, Surgeon, granted leave of absence for 14 days. Dec. 8, 1887.

J. M. Gassaway, Surgeon, granted leave of absence for 15 days, to take effect when relieved. Dec. 17, 1887.

Fairfax Irwin, Surgeon, relieved from duty as Acting Chief Clerk, Office Supervising Surgeon-General, and to await orders.

S. D. Brooks, Passed Assistant Surgeon, granted leave of absence for 30 days, to take effect when relieved. Dec. 15, 1887.

W. P. McIntosh, Assistant Surgeon, to proceed to Wilmington, N. C., for temporary duty. Dec. 13, 1887.

G. M. Magruder, Assistant Surgeon, granted leave of absence for 21 days. Dec. 19, 1887.

* P. M. Carrington, Assistant Surgeon, ordered to examination for promotion. Dec. 14, 1887.

CLINICAL LECTURE.

INFANTILE BRONCHO-PNEUMONIA.

A Clinical Lecture delivered in the Hôpital des
Enfants Malades.

BY DR. JULES SIMON,
PARIS, FRANCE.

Gentlemen:—Acute broncho-pneumonia is a disease whose symptoms and whose course vary according to circumstances. Sometimes the march is one of great rapidity (galloping broncho-pneumonia). Two or three days after the onset of the attack, the disease has spread throughout the entire bronchial tree to the extremities of the bronchioles, and the little patient dies asphyxiated. The cardinal symptoms are the intense dyspnoea and the high fever, which often mounts up to 104°F., and even higher; the oppression is excessive, the lips and face turgid and cyanotic, the extremities cold, the pulse small and feeble, and the patient is in the utmost distress till death ends the struggle.

Sometimes, on the other hand, the disease is less rapid in its progress, although still of the greatest gravity, and does not come to a fatal termination till after a week or ten days. It is only by degrees that asphyxia manifests itself. The extreme oppression is shown by the increasing frequency of the respiratory movements, by the restlessness of the patient, by the coöperation, in the act of respiration, of all the accessory breathing muscles, and by the livid color of the skin and nails.

This bronchial affection, whose gravity is almost sure to increase from day to day, reveals itself to auscultation by the presence of numerous subcrepitant and crepitant râles, which are heard in spots all over both lungs; sometimes also by the signs of a more or less limited hepatization, the foci of lobular pneumonia becoming confluent, and constituting that variety of broncho-pneumonia which has been called *pseudo lobar*.

These two forms—the galloping form and the slow form—are almost always associated either with a previous morbid state of the lung—a bronchial catarrh, for example—or with a general disease, like measles and whooping-cough, which affect principally the respiratory passages.

Broncho-pneumonia in its most rapid form is a formidable disease, and when once established, the physician can do but little to stay its progress. It will not do, however, to lose sight of the fact that, if suitable precautionary measures are adopted, this dangerous complication may often be averted. This is especially the case with measles and whooping-cough, where careful attention to the hygiene of the patient will not seldom prevent those pulmonary engorgements which are so much to be dreaded.

The third form of broncho-pneumonia is, at least from a therapeutic point of view, the most interesting. Its onset, like that of the other varieties, is almost always insidious and unexpected. If it be a case of whooping-cough, for instance, at a certain stage of the disease, when you happen to be examining your little patient in the evening, you are surprised to find the skin hotter than natural, the cough a little less paroxysmal

than ordinarily, but more frequent, and the throat red and congested. The child has taken a fresh cold, the parents say, and at first you think that this is actually the case, for you find nothing out of the way in the lungs, either by percussion or auscultation, unless it be a few slight râles scattered here and there. These symptoms, trifling as they seem to be, are often the precursors of serious mischief. There will be still greater reason for anxiety if the temperature rises rapidly to 104° , if the fits of coughing (to the delight of the parents, who do not know the evil import of this sign) are suddenly suppressed; and, unless there is reason to believe that an attack of measles is being ushered in—for measles and whooping-cough sometimes occur simultaneously—you may make up your mind that you have before you broncho-pneumonia in its incipency.

The next day the whole bronchial tree is involved; the dyspnœa is intense; the dusky, pale color of the skin, with the swollen and livid lips and the hurried respiration, indicate that asphyxia is already present.

Examination of the thorax presents exaggerated resonance, almost a tympanitic percussion sound in certain places, while in others there is a shade of dulness; auscultation discovers fine bubbling ronchi (crepitant and sub-crepitant), more audible in certain points than in others, and predominating at the basis of the lungs; coarser râles are heard higher up. The respiratory sounds, weakened or even suppressed in the tissue communicating with the inflamed tubes, are exaggerated on the confines, and elsewhere in the thorax. The temperature is high (103° – 105° F.), and the pulse frequent and small (130–140 per minute).

But there is one thing which is peculiar to this form of broncho-pneumonia: after three or four days there is a lull in the symptoms, and a deceptive promise of amendment; the temperature falls a degree, the pulse is less frequent, the suffocation and the restlessness less pronounced; and physicians and attendants hope that the dangerous crisis is passed. The next day the child is worse, and the asphyxia more imminent than ever; the abdomen is now tympanitic, and this adds to the respiratory distress. Again, after one or two days, there is another lull in the storm, and the parents take renewed hope; the cough is less troublesome, the dyspnœa less intense; and then the symptoms assume a more aggravated form.

The bronchial tree is thus taken by successive islets, and while the disease in certain points enters upon defervescence, it pro-

pagates itself elsewhere, invading regions hitherto healthy. We might compare its course to that of erysipelas, pursuing its march by successive invasions, each new region attacked presenting the invasion of a new pulmonary lobule by the disease which we are considering; and no respite is possible till the malady has spent itself.

The duration of this third variety of broncho-pneumonia is generally from three to four weeks, and during this long period of relapses and amendments the physician finds himself in a very anxious and trying position.

Under the influence of the general congestion, the kidney imperfectly performs its function; and to the phenomena of pulmonary asphyxia are added symptoms due to retention in the organism of urinary salts. Along with the general enfeeblement of function, the brain is congested; and although at times the condition of the lungs improves, the dyspnœa continues, from debility of the respiratory centre. Sometimes, moreover, there are accessions of suffocation and paroxysms of coughing resembling pertussis, provoked by the hypertrophied mediastinal glands pressing upon the cardio-pulmonary plexuses.

In cases which end favorably, after a prolonged fight of many days and even, it may be, weeks, the fever falls; the vomiting ceases; the dyspnœa, little by little, subsides; the urine becomes more natural in quality and quantity; and there is a general lull. But convalescence is slow and tedious, and recovery may not be completed till after a month or two of constant care.

As to the ratio of fatal cases to cases of recovery in this disease: while in hospitals where, as a rule, it is impossible to give as good care to the sick child as in private practice, the mortality is eighty per cent.; in private practice it is only fifty per cent.; but this affirmation is only true in its application to children above three years of age, for below that age the mortality is certainly much greater.

The differential diagnosis is not always as easy a matter as one might suppose. Simple pneumonia—which is, by the way, very rare in children—has its onset suddenly, without prodromes and is ushered in by a chill; while broncho-pneumonia always succeeds a previous attack of bronchitis, of influenza, of whooping-cough, of measles, of typhoid fever: in a word, follows upon some general disease, or some affection of the air passages.

How is it with the functional signs—are they sufficient to establish the diagnosis? In simple pneumonia there is pain in the side,

dyspnœa and cough; but the latter symptoms are much less pronounced than in broncho-pneumonia, where the cough is imperious and persistent, and the dyspnœa intense. I do not allude to the expectoration, which is a valuable symptom for purposes of diagnosis in the adult, but which is wanting in young children. In frank pneumonia, the face is flushed, while in broncho-pneumonia it is of a dusky pale or livid color.

In ordinary pneumonia, the physical signs are limited to one side; you have there percussion dullness, and, on auscultation, you note at the onset absence of the inspiratory murmur, and slightly blowing expiration: the latter bearing some resemblance to the puffing sound of a steam engine. You will not find fine crepitant râles as in the adult, but after several days you will detect a veritable tubular blowing sound, which is followed shortly by large returning crepitant râles.

Broncho-pneumonia is seated in both lungs; percussion gives in certain points an exaggerated, almost tympanitic resonance; in other places, especially at the bases, a slight dullness.

In simple pneumonia, you may have over the affected region exaggerated thoracic vibrations; there is nothing like this in broncho-pneumonia. Note, also, the different character of the auscultatory signs in the latter disease; you will, for instance, hear, scattered over both lungs, numerous unequal râles, dry and moist, crepitant and sub-crepitant. If you hear a souffle, it has not the true character of the tubular souffle, but seems a feeble imitation of the latter; is also very circumscribed, and changes its position in the thorax. The next day, on auscultating your little patient, you no longer hear the souffle of the day before, or it has changed its place,

To sum up, in broncho-pneumonia you have an abundance of signs furnished by auscultation; these signs are diffused, fugacious, mobile; while in true pneumonia they are confined to one place and persistent. Simple pneumonia, moreover, unless improperly treated, is not a dangerous disease in children; defervescence comes on from the sixth to the ninth day spontaneously and abruptly. I, of course, except infants under one year of age, in whom the disease is one of great gravity.

In acute phthisis, the diagnosis is still more difficult. Like broncho-pneumonia it begins insidiously, and generally in the course of some general disease; the dyspnœa is very marked, and the asphyxia and cyanosis are in direct relation to the extent of the lesions.

The aspect of the little patient is very similar in both cases; the pallor of the complexion, the violaceous coloration of the lips and extremities, which are the signs of approaching asphyxia, are as marked in the one case as in the other.

The physical signs are the same. And when it is a case of acute phthisis, running its course in a few weeks, I defy any one to name a differential sign of any value. There are the same crepitant and sub-crepitant râles disseminated over both lungs, the same blowing sounds especially audible over the roots of the bronchi. Therefore, I never feel so sure, when I have these signs and symptoms, that I have before me a case of acute phthisis, that I deem myself warranted in pronouncing an absolutely unfavorable prognosis. I have so often made the diagnosis of acute phthisis in desperate cases, and seen the little patient get well after several weeks of treatment, that I have learned the necessity of caution in pronouncing a definite opinion concerning such cases.

But now and then there are instances where the diagnosis is clearer. The examination of the apices, as compared with the bases of the lungs, discloses a predominance of lesions in the sub-clavicular or in the supra-spinous fossæ; the percussion dullness is greater in those upper regions of the chest, and râles, cavernulous bruits, and blowing sounds are more numerous in those points. In short, the morbid sounds decrease as we go from apex to base, and this is a sign which is almost peculiar to phthisis.

What shall be the treatment of infantile broncho-pneumonia? First of all, I insist that the little patient shall be kept in bed. If the child be less than a year old, you may find it difficult to enforce this requirement; the child is restless in bed, and insists on getting up. In such cases, you will do well to make a woollen sack and keep the little patient in it, covered with a thick shawl, and the legs wrapped in cotton batting. You can then take the child up and hold it on your knees, keeping it in a vertical position, which is better than the dorsal. But if the child is more than one year old, you can insist on it being kept in bed, the head and trunk elevated on an inclined plane. You will perhaps be surprised to see me urge upon you a requirement which seems to you so simple; but I deem it of great importance, and indeed the first condition, if your treatment is to have any real efficacy.

At the very onset of broncho-pneumonia, and when the fever is high, you may administer an emetic; but this is the only emetic

that I allow during the course of the disease. Later on, when the child is depressed by the disease and vomiting is difficult, you ought especially to guard against the exhibition of emetics, which will certainly do more harm than good, increasing the dyspnoea and general prostration. Nor would I advise you to give kermes, tartar emetic, or other antimonials which debilitate the vital forces. If in ordinary bronchitis you may employ with advantage—as you have seen me do—opiates, belladonna, aconite, codeia, do not think of prescribing them in broncho-pneumonia, where they cannot but be mischievous.

You should give your little patients stimulants to arouse the respiratory centre and pneumogastric nerve, whose functions little by little are depressed. Alcohol, in some of its forms, is indicated; so also is acetate of ammonium in the dose of four or five grains, or the carbonate of ammonium in such dose as can be borne without emesis. A good alcoholic preparation is Malaga wine, of which two or three teaspoonfuls may be given to a child under one year of age, and a proportionately larger quantity to older children. If the Malaga wine seems too sweet and disagrees, or the child refuses it, you may use Marsala, port, or brandy; and from the judicious use of these alcoholic preparations you will derive great benefit.

I add to the treatment by alcohol the sulphate of quinine. Morning and evening I give to a patient four years old three grains, and half that quantity to a child of two years of age, while for a child one year old a grain is sufficient. Both alcohol and quinine, under these circumstances, are antithermic and sustain the nervous system and heart; but it is particularly in enforcing and regulating the action of the heart that they do good.

This is about all I have to say relative to internal treatment. You should at the same time watch the state of the digestive organs; for distention and meteorism of the abdomen count among the causes which augment the dyspnoea; hence you will administer from time to time a little senna or magnesia to keep the bowels clear, while taking care not to provoke diarrhoea.

It has been said that the revulsive treatment in pneumonia and broncho-pneumonia is a thing of the past, without any proved action whatever on the state of the lungs. I am certain that this is a mistake, at least as far as broncho-pneumonia is concerned. I am, in fact, in favor of mustard sinapisms to the chest at the onset of the pulmonary affection, and am sure that I have often seen marked relief follow their use; after that I

apply dry cups to the thorax morning and evening.

I am also so old-fashioned as to believe in the efficacy of small fly-blisters about the third day, but they must be small—not more than an inch in diameter for older children, and less even for those that are younger. Not more than three or four should be put on at a time, and should not be left on more than three hours, whether they draw or not; then they should be followed by a potato-poultice, and afterwards dressed with vaseline and lint. Two days after the application of the first series, you may apply a second series over another region, and in the course of two or three days, still a third series, thus pursuing the disease in its different stages, and shifting localizations. You must take care that the blister be not left on too long; and you must not forget to apply the poultice in order to moderate the cutaneous irritation; and if you are particular to carry out this direction, you will never see ulceration, sloughing or suppuration follow these vesicants.

From the point of view of hygiene, see that the room in which your patient is kept is never hotter than 64° or 65° F. Support the strength of the child by broths, gruels, milk, egg-nog, etc.; and, if vomiting follows the fits of coughing, give a small quantity of the potion of Rivière (which may be replaced in American practice by plain soda water, or any ordinary effervescent mixture), a little Vichy or Vals water, or a few sips of coffee, made without any sweetening.

Lastly, if the restlessness be too great, and the nights too much disturbed, a lavement (enema) of chloral (starch water, two ounces; chloral, seven and one half grains) may be administered, or a grain or two of chloral may be given by mouth.

Do not forget that broncho-pneumonia is a disease of long duration, which demands of you much patience and careful watchfulness. You should then not readily yield to discouragements, and you will often see your efforts crowned with success in the recovery of patients whose condition long seemed desperate and even hopeless.

—Dr. Middleton Goldsmith, who recently died at Rutland, Vt., was one of the founders of the New York Pathological Society. A short time ago he gave the society \$5000 for a lectureship on nervous diseases. He is said to have been the first physician to introduce the use of bromine in cases of gangrene.

COMMUNICATIONS.

REMARKS ON SENDING PHTHISICAL
PATIENTS TO THE ROCKY
MOUNTAIN REGIONS.

BY L. HUBER, M. D.,

ROCKY FORD, COLORADO.

From the first settlement of certain parts of the Rocky Mountain region down to the present time there has gone forth a deserved reputation of these localities for the palliation and cure of certain pulmonary diseases. Year after year patients are sent westward to gain the hoped-for health which they unsuccessfully struggled after in the low damp climate of the East. Now, as this influx of invalids goes ceaselessly forward, may it not be well to consider the conditions which justify a physician in sending his patients into this western country? In other words, the circumstances under which it is advisable to recommend the high dry climate of Colorado and New Mexico to consumptive and asthmatic sufferers?

This is a matter which the medical profession in the region specified has often discussed. How repeatedly do physicians in the leading towns and cities of this section find persons sent here simply to have their symptoms aggravated, and death greatly hastened! How often do they find patients recommended to resort to this climate without any definite or adequate conception of the effect it has upon the human system? Either this climate has, or has not, peculiar qualities. If it has, it is necessary to know their effect on the healthy individual. If it has not, then it matters little whether it be recommended and resorted to or not?

The first inquiry is: When and how did the Rocky Mountain region gain its reputation for pulmonary diseases? Years ago, when there were no transcontinental railroads; when the lines of traffic and travel terminated in Omaha, St. Joseph, Leavenworth, and other like points, it meant much more to reach Denver, Pueblo, Santa Fé, and similar situated cities. The health-seeker came westward on the railroad to one or another of the former places, and then completed the rest of the journey over the plains in a stage-coach or on an emigrant train drawn by oxen. The inconvenience of this plan of transportation was more apparent than real, and it often proved of much practical advantage, and contributed greatly to the preservation of life and the subse-

quent improvement or recovery of the patient. It is obvious why this was so when we consider the different circumstances involved then and now-a-days. In patients suffering from pulmonary disease, a feeble digestion or actual dyspeptic condition is often an insurmountable hindrance to recovery. Often, too, the matter of occupation and exercise cannot be regulated. Overland transit obviated some of these difficulties. The invalid, conveyed in a laboring ox-team over the sunny, dry plains, or in the open stage-coach, had only the substantial provisions of the camp or garrisoned government stations. He was exposed to the air and sun, and soon acquired an insusceptibility to taking colds; and his system became better oxygenated, if I may use the expression; and his power of assimilation increased. Occasionally, the sight of wild beasts, the presence of herds of antelope and buffalo, or the onset of marauding Indians served to excite the circulation better than any physic, and broke the monotony so common to invalidism. These and other attending circumstances contributed ultimately to the welfare of the health-seeker. Moreover, on reaching his destination, he found no luxuriantly-equipped hotels, where he could confine himself away from sunlight, fresh air, and exercise, as is the case now. He found no crowded resorts where his society was largely, if not exclusively, among sufferers like himself, with whom the chief topic of conversation was bewailing their sad condition. The subjugation of the wilderness, the conversion of the prairie or unsightly sand-plain into a succession of homes and farms, and the building up of cities gave him occasions for mental occupation. He was forced among hardy pioneer classes, whose vessels were full of red blood, and whose life teemed with vigor and strength. Amid these surroundings the invalid was encouraged to live, not to repine; to hope, not to despair.

The next fitting inquiry is, what peculiarities are perceptible in healthy individuals within the Rocky Mountain region, and what changes take place in invalids who improve and recover here? That there is a fuller chest development in the natives and old inhabitants of elevated regions is an accepted observation. That the rarity and pureness of the atmosphere in high altitudes necessitate a greater expansion of the thorax is evident. Even in certain domestic animals this difference is noticeable. The native horse of Colorado and New Mexico has fuller measurements, as compared with the native

stock of the low prairies of the Mississippi valley. A horse capable of hard service in the latter regions is comparatively worthless in a great many instances, when brought to the mountains, and shows deficient respiratory power. Healthy men, who have never had their lungs impaired in any way, find themselves incapable of much or hard exertion on first coming here, and readily become "winded," and pant rapidly.

This being the case, how are individuals with impaired lungs and respiration affected on coming to the mountains? This is an important inquiry, and one which the medical man should comprehend, before he can intelligently advise patients to come here. After quite a number of observations, the writer has been led to several conclusions:

First.—If the patient is still well within the first stage of pulmonary disease, there may be slight hemorrhages at the first, unless he ventures cautiously into elevated localities. If he is in the second stage, when considerable areas of the lung tissue are softening or approaching this condition, there will be more rapid breaking down of the parts for a time. If the patient's energies are yet unexhausted and capable of offering resistance to these more rapid destructive changes, he may pass over this first aggravation and recuperate, with a temporary or permanent arrest of the disease. Under these circumstances cavities form and remain in an uncurable condition, and the vital powers improve.

Second.—If the disease is well established, has gone nearly through the first stage or reached the second; if the patient's constitution has not offered considerable resistance to its inroads—shown a *tolerance*, according to Prof. Flint; if there be any marked derangement of the circulation, and a tendency to weakness or exhaustion of the organs thereof, little good can be expected from his going to a high altitude. Indeed, such cases generally grow rapidly worse, and often quickly prove fatal.

Third.—Patients who have been vigorously medicated until agents have ceased to effect the system uniformly and readily, are not in good shape to seek health in a new country and climate, no matter what stage the disease is in. Newcomers undergo a process of acclimatization in this Western country, and are for a time susceptible to certain atmospheric and teluric influences, the effect of which must be averted or remedied by proper medication. If the stomach is already disordered by much medicine taking, or the nervous system is unresponsive to

remedial agents, the chances are that the physician is left powerless to benefit the case, in certain critical stages.

From these observations it is plain what advice the physician should be prepared to give those who seek his counsel about a change of climate. The time to counsel a patient to come to this Western country is at the earliest onset of the disease. The less of inroad it has made, the greater the certainty of improvement and recovery. In seven cases out of every ten, the writer believes it would be greatly to the benefit of the patient, and contribute largely to the permanent arrest of his disease, to send him into the dry, elevated climate, just as soon as the premonitions of pulmonary disease are ascertainable. In families in which a tendency to pulmonary disease is known to exist, it is advisable to counsel early removal. Prevention is better than cure, and that such a change would be prophylactic few can question.

In counseling patients to come to the West, it is unwise to urge a visit for only a few weeks or months, until improvement sets in and the patient becomes strong. It is a fact beyond dispute that phthisical patients, who improve in this high and dry climate, are incapacitated for return to the Central and Eastern States. On their return they rapidly lose what they have gained, and not only does this take place, but also they lose the power to recuperate on a second resort to the West; and their chances of improvement and recovery are immensely reduced. It is such a frequently repeated event to see a patient who has responded to the climate grow strong, then return, and lose all he has gained, that it cannot be too strongly urged upon physicians in the East to insist that with improvement the patient should reside permanently in the locality he has found helpful to him.

The selection of some one point, and remaining there, is far better than traveling from place to place, and should be insisted upon. The altitudes of different resorts vary considerably, and a person with impaired lungs is not able to change from one to the other without loss, indeed, often not without danger. It is best to begin with an elevation not exceeding 5000 feet. Even such an elevation as this should not be resorted to at once. It is a common occurrence for patients who have made a quick transit from the seacoast, or from the Central States to suffer from hemorrhages upon arrival, and his impoverished lung is still further deprived of nutrient fluid. There are not a few cases

on record in which sudden death has resulted from this cause. The better plan, therefore, is for invalids in moving westward to stop a week or more at intermediate points, where the elevation is less than 3000 feet. In this way the lungs adapt themselves, to some extent, to the rarified atmosphere from which they must take oxygen for the system. At such a point, a patient can move about more easily, and more safely inure himself to a certain amount of out-door exercise, than in a more elevated locality.

Another duty incumbent upon the medical attendant is the careful classification of his patients. Allowing for a necessary and excusable number of mistakes, it nevertheless seems that proper care is not taken to discriminate laryngeal, bronchial, asthmatic, and phthisical cases in the adoption of treatment by climate and elevation. If a chronic laryngitis or a chronic bronchitis has its cause largely in sudden weather changes, in a damp, vapor-laden, cold climate, then there can be no mistake in sending the patient to some part of the Rocky Mountain region, between a point as far north as Denver, and one as far south as Albuquerque, New Mexico. Within this range every variety of altitude can be found, and a winter climate of any degree of intensity or mildness. The prevailing advantage of all is a dry soil and a dry atmosphere for the greater part of the year.

In the case of asthmatics, less care need be exercised as to altitude. It is to altitude that they owe much of their relief. The difference of atmospheric pressure in elevated districts has a mechanical relation to the disease, in not a few instances. It is not best, in many cases, to recommend these patients to the older cities or older settled regions, for *atmospheric dust* is more likely to keep up the disease in such places.

The want of uniformity of results in patients sent West is largely due to disregard of the precautions I have enumerated. Much has been written and spoken about the climatology of the region specified, and its relations to the pulmonary diseases. Unfortunately it has often been in a way that helped but little to guide the physician in his advice to patients. Unless the observations herein set forth be used as a guide to some extent, the sad experiences will continue of *persons sent to these regions only to have their death hastened*. So frequently are these ill-advised cases brought to the notice of the busy physician in this Western country, that he is forced to entertain the suspicion that it is one method his Eastern

co-laborer adopts of escaping the inevitable termination of his treatment. It is cruel to elate the hopes of an advanced consumptive by the history of brilliant recoveries, and in this mood incite him to leave his home and friends, to have his death precipitated in a region in which he has no capacity to live. The profession has gathered much valuable knowledge about the natural history of consumption, and it readily recognizes the premonitions of the disease in many instances. Why, then, hold on to cases with the hope of curing them, when climate and country are antagonizing every effort made, and when all means of combating the disease, and all recuperative power are expended, send the patient West for a new lease of life. Is it a mere fancy, a mere chimera, with our Eastern colleague, that somewhere in this distant *terra incognita* there is a "fountain of youth," whose delectable waters will restore the wasted and devitalized tissues and make the dying man live? We give him more credit for knowledge. Let him consider that with the favorable influence of climate and country and the same scientific measures that are at his disposal, we can achieve results greater than he has achieved only when we can take hold of patients early. This should be the guiding thought in sending consumptives to this region for cure.

THE CONJUGAL BURDEN.

BY JANET E. RUNTZ-REES.

The carelessness with which responsibility is assumed in life is very remarkable; in no case more so than in the conjugal relation. Young men and women, and indeed older persons, enter upon matrimony with the scantiest idea of its meaning, and with no regard at all to its obligations.

Marriage as a civil relation is a mere contract. Its esoteric meaning is not in the least degree important in the law, and this is possibly one reason of the flippancy with which the institution is regarded. Many a man pays more regard to the making of his will than to the issues of his daughter's marriage; and the real meaning and importance of the marriage ceremony has been very little, if at all, emphasized by the religious service which many persons look upon as more binding than the legal aspect of the affair.

Regarded as a civil institution, marriage, as consummated among ourselves, is a fair bargain. Yet very few of its participants

realize in what degree and measure it is so. The fact stands thus: The husband on his part assures the wife of a home (bed and board, as the law has it) in return for what? Vulgarly speaking, he expects from her possession of her body, and (should he set a value upon it) of her soul. He expects her to bear him children. And this, so far as it goes, is perfectly legitimate and right. Both parties to the contract know, or ought to know, what they are undertaking, and so long as the man affords a home and his careful protection to the woman, so long by the terms of contract he has a right to her maternal possibilities. So far it is a mere matter of business. If, in carelessness, ignorance, or from an inherent lowness of nature, either party break the contract, he or she is responsible, and the other partner has a perfect right to demand compensation. The man is fairly aggrieved if the wife refuses him his legitimate rights; the woman is rightly angered if in return for her maternity she does not receive consideration, affectionate solicitude, care and kindness.

But there is another, and a far more serious side, to the marriage question. One, alas! rarely considered, yet one upon which hinges the entire happiness of generations, their physical, mental and spiritual well-being.

It is the question of questions to-day—for the old reverence for marriage, as marriage is dying out, and public regard for it as a mere business contract is small.

The burden of conjugal union should justly be borne equally by both participants. Its objects should be plainly understood by them before its responsibilities are incurred, and once understood neither has a right to object to any sacrifice or suffering they may entail. If motherhood on the woman's part is her share of the contract, she may not justly object to bearing children, while the man, desirous of parentage, has it certainly laid upon him to sacrifice all else, even his amorous passion for the sake of or even for the advantage of those whom he protects. When, from ignorance or malice, either party to the contract fails to carry out his or her obligations, serious results must ensue.

The woman who shrinks from motherhood upon the ground of physical discomfort and suffering, or because the bearing of children impairs her beauty, is so clearly in error that she deserves only contempt; but she is less blameworthy if, during the period of her gestation and motherhood, the husband fails in caring for and tending her, or forces upon

her the unacceptable evidences of his passion, and exacts a return of ardor which physical discomfort often renders impossible, or at least irksome.

It is incumbent upon him to do his part, *to cherish* his wife. If this entails some sacrifice, is not sacrifice the delight of all true love? It is an unjust thing upon his part to expect in a mother, or an expectant mother, weighted with the cares of offspring, the jubilant compliance of early nuptial days. And, too often, he lays upon her an added burden in the shape of anxiety as to means and many petty household cares. These, he says, are her province. True, but it is his duty to see that in ruling her kingdom she is provided with all requisites and spared all possible exaction. When this is done, he has in some measure fulfilled his obligation to cherish her, but by no means to its full extent. It is clearly his duty to partake as much as possible in the burden of child-bearing. This does not mean that he is to be the slave of every whim of an exacting woman; but it does mean that he is to live above mere animal gratification of passion or desire, and consider, before he indulges his manly wishes, how far his doing so is conducive to the well-being of the wife, who for his sake is facing her responsibilities cheerfully, and whether or not in exacting marital privileges he is in the remotest degree affecting by it, the child which, if it has any right to be at all, has it as evidence of love.

The question of sexual indulgence, its extent and claims, can never be definitely settled, because it varies in isolated cases. No two men, nor women, probably, are moved in precisely the same way by its claims; to some it is all powerful, to others scarcely existent. But there is one truth in connection with it which, recognized and accepted, would clear the conjugal question of all difficulty. It is very simple. It is only this: The man or woman who cannot subordinate passion to love is little better, if indeed any better, than an animal. The distinction between man and brute lies in the possession by the former of the higher instincts of morality. Moral affection lives in a region in which passion, as passion, claiming indulgence for mere indulgence sake, does not exist; in which *continence* in the man answers to purity in the woman; in which unselfish, self-sacrificing love alone controls desire.

When we reach a higher standard of morality, the myriad difficulties of the conjugal relationship will disappear in the light of unselfish love, and with them will also dis-

appear that blot on all civilization, *prostitution*. Men are often held wholly responsible for the outcasts on our streets, and no doubt in the beginning they were so, but they are no longer the only offenders. Every woman, married or single, is in her way also responsible, if she accepts of her husband or lover a lower morality than the highest, if she condones looseness of conduct either in lover or husband, if she fails, as a wife, to render all that is justly his, or to exact, on the other hand, the care and consideration which is justly hers. Men do not love their wives less, but more, for taking thought for them; and this thought naturally includes consideration in the sexual relationship. They often err through ignorance, so do wives; but both would *find knowledge* if both lived in purity and continence subordinating passion, and its unreasonable demands to prove unselfish self-sacrificing love.

SOCIETY REPORTS.

NEW YORK ACADEMY OF MEDICINE.

Stated meeting December 15, 1887.

The President, A. JACOB, M.D., in the chair.

The Modern Treatment of Strangulated Hernia.

DR. T. HERRING BURCHARD said that his paper would be a review of the modern treatment of strangulated hernia, as he had nothing new to offer. Some of the facts brought out by modern experience with strangulated hernia were cited. There was now more general recognition, on the part of the profession, of the value of time in the early stage of strangulation. He contended against the habit on the part of some to procrastinate until important pathological changes had taken place in the strangulated tissues. Taxis should be employed with care, and not persisted in for an undue length of time; twenty to thirty minutes was usually long enough. When it had proven useless, an operation should be resorted to. Antisepsis was, of course, to be observed. Regarding the treatment of the sac, free and impartial judgment was required; but no operation for strangulated hernia could be regarded as properly performed which did not finally close the hernial canal. By this means we obtained isolation of the peritoneal cavity, prevented inflammation extending to it, and offered the patient a chance for permanent

relief against hernia. Dr. Burchard gave a brief review of seven cases of strangulated hernia upon which he had operated; five of these were in males and two in females. In combating stercoraceous vomiting and collapse, he had found nothing equal to the stomach douche with hot water. As a factor in the treatment of acute peritonitis, he mentioned the fact that concealed hernia, as the cause of such peritonitis, was apt to be overlooked.

How should the Sac be Treated in Herniotomy?

DR. R. F. WEIR read a paper with this title, in which he dwelt principally upon three questions: First. Did this additional surgical procedure for the prevention of a return of the hernia increase the mortality? Second. How is this additional operation to be performed? Third. How reliable is this procedure?

For the solution of the first question, only incomplete figures could be furnished. The statistics at hand of cases treated for radical cure of the hernia gave a lessened mortality over previous operations of from fifteen to twenty per cent. But it should be remembered that there had come to be a feeling, both among the laity and the profession, of the necessity of operating early, which rendered the chances of recovery greater. The treatment of the pedicle varied among different operators; but all agreed at present as to the necessity for closing the mouth of the sac. Dr. Weir had resorted to Nussbaum's method in five cases, and to MacEwen's in one; and he gave his preference for the former as being the simpler and more quickly performed. In his first cases he employed a flat truss just after the operation, but his own impression, and that of many others, was growing in favor of a simple bandage.

Regarding the third question, does this procedure give permanent relief from the hernia? Statistics showed a sufficient number of relapses to lead us to say, at least, that the operation is not yet perfect.

The Conservative Treatment of Irreducible and Incarcerated Hernia.

DR. W. B. DE GARMO said that in treating of this part of the subject he would make no reference to strangulated hernia. He would maintain that the abandonment of these cases (cases of irreducible and incarcerated hernia), after a hasty examination, was entirely unjustifiable, and that to decide upon operative measures after a few moments consideration was equally unjustifiable, for the reason that a good percentage of them

could be relieved by safer methods. In illustration of these views, Dr. De Garmo read the histories of ten cases in which he practiced a form of long-continued taxis. He began at the bottom of the tumor, and made gentle manipulation of the contents as if freeing them from their adhesions, repeating the operation perhaps daily for a week or more if necessary, until finally the tumor became reducible. He would not give a case up as hopeless until this method had been tried for two weeks. It was better that the patient should keep the bed during the treatment, although several of his patients continued about their business. Nine of his ten cases had inguinal hernia, the contents being almost invariably omentum and intestine. The duration of the hernia had been in five cases ten years, in four cases five years, in one case one year. The result of the treatment had been seven reductions and two failures. In one case it was abandoned because of a diabetic condition. Mechanical support should be employed after reduction.

Strangulated Hernia in Children.

DR. A. G. GERSTER, in speaking on this subject, said he would consider only those points in the operation which differed from the operation in adults. The difference of treatment in the two classes of cases related to the treatment of the wound. It was of the greatest importance to avoid inflammation of the wound in children. It had been suggested by Dr. Weir and Dr. Abbe that the ordinary operation for hernia would be the better if the external wound were not closed, but was allowed to heal by granulation; the idea being, that by the formation of a dense and massive external scar, intra-abdominal pressure would be resisted. In cases of grown persons, Dr. Gerster did not share their opinion, but in cases of children he would certainly advocate the open treatment of the wound. His opinion was based on the fact that in all the cases which had come under his observation, five in number, in which the wound had been sutured primarily, union of the external wound did not take place. Soiling of the wound by the clothes, urine and fecal matter could not be avoided. He believed that it was, therefore, better to pack the external wound with iodoform gauze and treat it as an open wound, just as one would treat a wound in the vicinity of any of the natural orifices.

Dr. Gerster related one case in particular, because of an error in diagnosis which had been committed. The child, two years of age, had a fluctuating tumor of the scrotum

which had existed for some time, but which could not be reduced by taxis. The tumor was translucent, and hydrocele was diagnosed. To make sure of the correctness of the diagnosis, he punctured the tumor with the hypodermic needle and withdrew fecal matter with serum. The child had no symptoms of strangulation, and was sent home; but next day symptoms of a strangulation developed, and an operation was performed. A second case was interesting from the fact that the child was subject to attacks of eclampsia, and during the attacks would develop strangulated hernia, which the family physician had always been able to reduce under chloroform. Dr. Gerster was called upon in one of these attacks, and after they had reduced the strangulated hernia in the usual way with chloroform, he performed a cutting operation, which resulted in a cure of the hernia.

In the discussion which followed the reading of these papers, DR. GIBNEY said it was the custom, in case the surgeon's operative measures proved unsuccessful, to lay blame on the general practitioner for having employed taxis for too long a time; but he had known many cases of reduction to take place after the employment of taxis for a considerable length of time. He had never seen a case of hernia in a child under two years of age which he could not reduce under chloroform, and when reduction had been effected the case could be cured by the use of a truss.

Dr. Gerster said, as bearing upon the paper of Dr. De Garmo, that in twenty-four operations of hernie of different kinds, he had found adhesions in the scrotum in only one case, that being a case of congenital hernia in an adult. He understood Dr. De Garmo to say that in several of his cases there were adhesions in the scrotum which he felt give way under manipulation.

Dr. De Garmo explained that in only one case did it seem that adhesions could be felt breaking down in the scrotum.

The discussion was participated in by DRs. JONES, FRUITKNIGHT, W. GILL WYLIE, and the President.

—The Rotunda Lying-in-Hospital, of Dublin, one of the largest hospitals of its kind in Europe, has been left without funds by the action of the town council. It seems that the Board of Governors of the hospital is largely Protestant, and that the council desire to have some representatives of their own religious persuasion on the board.

BRITISH GYNECOLOGICAL SOCIETY.

Meeting of Wednesday, Nov. 23, 1887.

G. GRANVILLE BANTOCK, M.D., President,
in the chair.

Retained Products of Conception.

DR. EDIS exhibited the placental portion of an ovum, which he had removed from a patient three months after a miscarriage. There was no feter, the placenta having apparently retained its attachment, at least partially, to the interior of the uterus. Hemorrhage had persisted on and off the whole time, and the anæmic condition of the patient was evidence of the severity of the loss. The uterus was found to be very bulky, and a portion of the placenta protruding from and tightly gripped by the cervix. The case well illustrated the necessity of examination in all cases where uterine hemorrhage persisted.

DR. AVELING believed, when the uterus was sufficiently dilated to admit the finger, it could be used to clear out the cavity far better than any ovum forceps yet invented. By pressing the uterus down from above he had never met with a case in which he was unable to reach the fundus.

DR. HEYWOOD SMITH found the following method generally successful: The cervix was rapidly dilated with graduated sounds, and then, after having removed with small uterine forceps any fragments of placenta that could be reached, he freely applied the solid nitrate of silver to the interior.

DR. GRIGG, DR. CHALMERS, and others also made remarks.

Tumor with Twisted Pedicle.

THE PRESIDENT exhibited a small, dermoid, ovarian tumor, which he had removed the same afternoon. He had previously pointed out that the condition of twisting of the pedicle might frequently be diagnosed from the history of the case, as in this instance; that, when rotation occurred, the symptoms were in proportion to the rapidity and completeness of the strangulation.

The Nature of the Hymen.

MR. BLAND SUTTON pointed out that the vagina was formed in the same manner as the rectum by an invagination of the epiblastic layer, termed the proctodæum, coming into contact and fusing with the posterior segment of the primitive gut. The distinction between the two parts remained throughout life; for, in the rectum, a ridge of adenoid tissue marked the situation where

the squamous epithelium of the anus joins the columnar cells of the rectum. In the vagina the corresponding spot was indicated by the hymen or its remains.

The mode by which the proctodæum and the gut became fused was as follows: When two cul-de-sacs came into contact and exercised pressure upon each other, the edges gradually cohered and joined organically. At this stage the lumen was yet obstructed by a thin septum. This gradually became thinner from pressure, and ultimately perforation took place. The hole gradually increased, and the septum slowly disappeared until a complete channel was the result.

In the case of the anus, it was clear that, if the invagination failed to reach the gut, an imperforate rectum would be the result. From a study of these conditions, he was convinced that the hymen was merely a thin septum resulting from the imperfect coalescence of the proctodæum with the uro-genital section of the cloaca. Should the septum be complete, it was termed an imperforate hymen. Occasionally the perforation was multiple, eccentric, or cribriform.

Similar evidence as to the nature of the hymen was obtained from the opposite end of the alimentary canal. The mouth and pharynx, with the associated structures, were derived from an involution of the surface epiblast named the stomodæum. This met the blind anterior end of the foregut at a spot eventually corresponding to the cricoid cartilage. Should these parts fail to unite, an imperforate pharynx was the result; when the coalescence was imperfect, then a hymen-like diaphragm might be found. So far as the alimentary canal was concerned, diaphragmata of this nature occasionally existed between the pharynx and the œsophagus, in the duodenum immediately above the entrance of the bile-duct, and in the rectum at the point of union of anus and gut.

Thus the formation of a diaphragm, sometimes complete, but more commonly perforated, at the entrance of the vagina, was only in agreement with what occurred in other parts of the body when two cul-de-sacs coalesced to form a continuous passage. Lastly, abnormalities of the vaginal orifice were not infrequently associated with defects of the alimentary canal, as might be expected, taking into consideration its embryological relations with the cloaca.

Enucleation by Electrolysis of a Large Uterine Fibroid.

DR. HOLLAND read notes of this case. Mrs. C., aged thirty-eight, mother of seven

children, was admitted into the Hospital for Women for uterine hemorrhage, which resisted all usual remedies. The uterus was much enlarged, reaching to the level of the umbilicus, and the sound passed to a depth of seven inches. There was no cervix available for a stump, and electrolysis was considered a legitimate procedure. The current was applied in the usual way on several occasions, the strength being gradually increased to three hundred milliamperes. Necrosis of the tumor resulted. This, with the help of the ecraseur, was successfully enucleated. On the second evening after this operation the temperature rose to 104° ; but was quickly subdued by quinine and the intra-uterine douche. The patient made a satisfactory recovery, and the uterus was found to have returned to its normal size. Dr. Holland remarks that the tetanoid contraction into which the uterus was somewhat persistently thrown by the electrical excitement on each occasion, led him to anticipate necrosis and enucleation as possible and probable contingencies. He also draws attention to the diagnostic importance of the galvanic current in tumor of uterine constitution, as by its means such tumors are so hardened and defined as to at once isolate them from any others with which they could reasonably be confounded.

DR. IMLACH said that Apostoli's treatment was almost as full of promise as were the electropathic belts so freely advertised at present. There was scarcely any pelvic disease it was unable to cure, and that it caused uterine fibroids to slough out was the only thing as yet unclaimed for it. Dr. Holland

has now shown that it would do even this. It was doubtful, however, what part electrolysis had played in this case. It was possible that the fibroid was lying in the uterine cavity ready at any moment for extrusion, and that any irritant or cautery would have acted as well.

DR. MANSELL MOULLIN thought the operator was much to be congratulated on the successful result of his case. He could not help thinking that the element of good fortune had been largely present throughout. His patient had been fortunate in escaping the dangers of septicæmia, which every one knew was a very imminent danger in the case of a sloughing fibroid. It was to be trusted that the operator's explanation of the reason necrosis had taken place was the correct one, thereby presupposing a strong uterine wall outside the tumor. It would be most undesirable when employing the current to establish necrosis in a tumor which was either subperitoneal or interstitial. Dr. Mansell Moullin thought that in suitable cases of submucous fibroids the electric current would be found of much service in connection with the operation of enucleation. Its action was to hasten the process which nature was in many instances already attempting to effect. It forced the tumor downwards and through the cervix, thus dilating the passage and bringing the tumor within reach of the operator. There was no evidence of any diminution in bulk as claimed for the electrolysis by Apostoli, and, in the numerous instances in which he had seen the treatment carried out with that view, failure had resulted without exception.

EDITORIAL DEPARTMENT.

PERISCOPE.

Therapeutics of Salol.

Three papers upon salol have lately appeared in the *Therapeutische Monatshefte*, 1887, Nos. 47, 51, 52. The first of these is by Bielschowsky, on the treatment of acute articular rheumatism with salol; the second is by Rosenberg, on salol as an anti-rheumatic; the third by Feilchenfeld, on experiences with salol. From a review of these papers in the *Centralblatt f. d. med. Wissensch.*, November 5, 1887, we learn that Bielschowsky treated twenty-seven cases of acute articular rheumatism with salol; and that nineteen of these cases were promptly and completely

that fourteen of them had the disease in a severe form. In two of the remaining eight cases, salol had only a slight action, and the patients were cured with salicylate of sodium; while in six, in spite of subsequent treatment with salicylate of soda, the disease assumed a chronic form. Relapses were observed eight times. The author thinks that even if salol has no greater anti-rheumatic activity than salicylate of soda, it is still to be preferred to the latter, inasmuch as large doses of it do not produce toxic symptoms. Only one patient had slight ringing in the ears, and one other eruptions at times. Skin eruptions, sweats, and stomachic disorders were entirely absent. The author generally gives seventy-five grains of the drug in five hours, but in a cured by the drug, notwithstanding the fac

few cases one hundred and twenty grains in eight hours.

In the second paper, Rosenberg notes the action of salol in articular rheumatism as in general very prompt. Relapses, however, seem to him, in spite of active treatment with it, to be more frequent than after treatment with salicylate of soda. Complications are not wanting. In opposition to the statements of Bielschowsky, the author frequently saw ringing in the ears and sweats: more rarely nausea, eructations, and vomiting. On the other hand, persistent disturbances of digestion, such as occur after the use of salicylate of soda, were not observed.

In the third paper, Feilchenfeld states that he has used salol for catarrh of the bladder, in doses of fifteen grains, two or three times a day, and has obtained good results. Alkaline urine became acid, the quantity of pus contained in it was diminished, and the quantity of urine increased. In some cases the drug had to be discontinued on account of causing too frequent micturition. Other disagreeable effects were not noticed. The characteristic color of carbohc urine, which frequently occurs, soon disappeared in spite of repeated use of the drug. The author thinks that salol can also be profitably employed in the treatment of leg ulcers. In one patient who had had a bubo removed, which was the result of a chancroid, the wound subsequently became chancroidal. In this case, after other remedies had been used without success, salol effected a cure. On the other hand, he saw no good results follow its use in tuberculous ulcers.

On the Treatment of Cerebral Hemorrhage.

Dr. Leonard Bradden, discusses in the *Lancet* the treatment of apoplexy, and recommends immediate compression applied to the nearest arterial trunk. If the seat of the hemorrhage is diagnosticated, the carotid upon that side ought to be immediately compressed, and the pressure should be kept up for several hours. If it should be impossible to determine the site of the lesion, both carotids might in grave cases be compressed. If continued pressure cannot be applied efficiently, the carotids on the side of the lesion ought to be tied.

In some grave cases, when the mechanical pressure of the hemorrhage is the principal element of danger, Dr. Bradden believes that trephining is indicated, to give issue to the effused blood. He insists on the sitting posture (less blood going to the head in sitting than in the recumbent position), and

the internal administration of nitrite of amyl and the nitrites generally, pilocarpine and the tension-decreasing remedies. Warmth to the hypogastrium, and hot baths, act similarly. He would eschew the external application of cold, "for cold externally, means congestion inside." In short, the time-honored treatment is, he thinks, all wrong; and even the utility of purgatives is, he believes, a moot question.

A Case of Chyluria.

An interesting case of chyluria was reported by Rossbach at the Sixth Congress for Internal Medicine, held at Wiesbaden in the preceding spring. The patient was a "fat anæmic," of twenty-one years, with a compensated mitral insufficiency. Day and night she passed a milky, cloudy urine, the amount of which fell in an extraordinary manner just before the menstrual period to as low as 14 ounces, then rose and was not seldom above normal. It showed moderate coagulation, and, microscopically, numerous fat-drops of various sizes. The amount of fat varied between 1.5 and 10 grains. There were, beside, a few white blood corpuscles, fibrine generators, and several varieties of albumin. Careful examination showed that the albumin and fat must have entered the urine through the kidneys, and that the fat came partly from the body itself, partly from the food albuminates. Fasting for several days had no effect in increasing the amount of fat excreted. By excessive feeding with albuminates and carbohydrates and withdrawal of fat the excretion of fat increased fourfold, but fell on the addition of fat to the food.

The patient had an abnormally small area of liver dulness, and it is not impossible that all the symptoms depended on some morbid condition in the liver.—*Schmidt's Jahrb.*, October, 1887.

A Case of Raynaud's Disease.

At the meeting of the Midland Medical Society, held October 19, 1887 (*Lancet*, November 12, 1887), Dr. Suckling showed a strumous-looking girl, twelve years old, who was suffering from symmetrical gangrene of the fingers and toes. When two years old she was bitten on the right forefinger by a rabbit, and three months after this the fingers began to be blistered. Since that time she has never been free for a month from a sore finger or toe. She suffers from paroxysmal attacks of inflammation in the fingers, accompanied with severe pain. The terminal phalanges, with the distal half of the middle

phalanges, are lost in the fore, ring and little fingers of both hands; the fingers themselves are swollen red, and ulcerated at their extremities. The thumb is inflamed and the terminal phalanx is necrosed. There is no anæsthesia and no pain. The skin of the legs is bluish and thin, and ulcerated in several places, the slightest injury causing an intractable ulcer. The terminal phalanx of each little toe has been necrosed. The knee-jerk is present, the plantar reflex is lost. The condition of the extremities is always worse in cold weather. There is no history of struma in the family, but the girl herself is weakly and ill-nourished.

Resorcin in the Treatment of Venereal Warts.

A new method of using resorcin in the removal of venereal warts is recommended by Boech. of Christiana (*Monatshefte f. prakt. Dermat.* v, p. 93, 1886). After removal of the warts by the scissors or sharp spoon, a four to six per cent. watery solution of resorcin is applied, and removed every four or five days. If the disease returns, a powder—eight parts of resorcin to one of sugar, bismuth, or boric acid—is sprinkled over the wound, and absorbent cotton applied over it. As the remedy is very irritating, it cannot be used long in strong solutions, but must be alternated with a weaker solution of the same, or of nitrate of silver. It can obviously not be left in the patient's hands.

On the Etiology of Tetanus.

Giordano reports the following interesting case (*Giorn della accad. di med. di Torino.*, 1887, No. 3, 4): A man of 40 years fell from a hay-loft to the frozen ground, and was admitted to the hospital twenty hours later with a complicated fracture of the forearm. The wound was very dirty. It was dilated, cleaned with sublimate solution, drainage applied and partially sutured. On the fourth day trismus appeared; on the seventh death from tetanus. Giordano at once removed some blood from the wound, and placed it, as well as pieces of thrombosed vein and median nerve, at once in sterilized bouillon. A fragment of necrotic tissue contained microbes, but not the bacillus of Nicolaier. Inoculation had a negative result, as had also inoculations and cultures of blood and median nerve, medulla, spleen and pus from an abrasion on the lip. On the contrary, pus from the sheath of a vessel in the wound, and that from a thrombus in a vein, produced tetanus in rabbits and guinea-pigs.

Particles of straw from the place the man struck on falling, when inserted under the skin, produced tetanus in a rabbit in three days. The pus from this animal contained a few specific, and many other bacilli, and caused tetanus in two other rabbits. From the latter, other rabbits were successfully inoculated. Infusion of the medulla did not produce tetanus. An infusion of the dust from the locality had no effect, but inoculations of a culture of it six days old caused tetanus, and the culture contained a few specific bacilli.

Giordano emphasizes the fact of material from the surface of the wound being sterile, while that from the deep part and the thrombus were effective. He believes that as the other organs did not contain the tetanic poison, it could be assumed that the lethal effect depended on substances absorbed from the wound. He very properly ascribes the sterility of the superficial materials to the antiseptic used, while the thrombus and deeper lying pus were not reached by it, and therefore capable of exerting their wonted effects. The practical conclusion to be drawn from the latter fact is evident.

Severe Blow on the Loin followed by Copious and Long-continued Hæmaturia.

The *Lancet*, Nov. 19, 1887, reports the case of a well-grown, muscular laborer, who was admitted into Middlesex Hospital, December 14, 1886, under the care of Mr. Hulke. He was suffering, at the time of his admission, from concussion of the brain and a scalp-wound, and, in addition to these injuries, he had a bruise on the left loin. He was said to have fallen headlong off a scaffold twenty-eight feet above the ground, and to have struck his left side on a projecting beam. The first urine which he voided contained a very large admixture of blood, and the hæmaturia continued, with slight variations in the quantity of blood, until December 25, 1886, when an evident decrease was first noted, coincidentally with the exhibition of acetate of lead in doses of three grains every three hours. Traces of blood did not finally disappear from the urine until January 3, 1887, about which date a small quantity of pus was noticed in it, and a few hyaline casts.

With reference to the cause of the hæmaturia, Mr. Hulke remarks that it hardly admits of doubt that the source of the hemorrhage was the kidney, which had sustained some degree of laceration; for the amount of blood was too great to have proceeded from the ureter, and there was not anything

to suggest an affection of the bladder. That such lacerations of the kidney are not necessarily fatal without operative intervention is, he believes, abundantly established by experience; and they do not necessarily demand nephrectomy, which should probably be restricted to the severest forms of injury. In this and in other similar cases, acetate of lead has appeared to him to be decidedly useful.

Quiet Iritis.

At a meeting of the Ophthalmological Society of London, on November 10, 1887, Mr. Johnathan Hutchinson, Jun. (*Lancet*, Nov. 19, 1887), related several cases of quiet iritis in which the attack, sometimes leading to extensive adhesions to the lens, and involving much deterioration of sight, was from the first unaccompanied with the typical features of inflammation. It was, perhaps, not sufficiently known that iritis in certain cases did not reveal its presence by the characteristic frontal pain, and was practically unattended by congestion or photophobia, though this fact had been pointed out by various ophthalmic surgeons. He had tabulated thirty-seven examples of quiet or insidious iritis, and from these deduced the following conclusions:

1. Sympathetic inflammation, congenital syphilis, and inherited arthritic (gouty or rheumatic) tendency are probably the most frequent causes of quiet iritis.
2. This form is very rare in the iritis of acquired syphilis, that of the ordinary rheumatic type, and in traumatic or herpetic iritis.
3. Sex and age have little or no influence in modifying the severity of the symptoms accompanying iritis.
4. That a constitutional tendency cannot always be invoked as the reason for the fact that iritis takes on an insidious form, is shown by the occasional occurrence of two attacks in the same patient, one being accompanied by violent inflammatory symptoms, the other perfectly quiet throughout.
5. The absence of the ordinary symptoms of iritis by no means always implies a mild course of the disease, some of the cases going on to complete blindness of the affected eye.

Cystic Tumor of the Cerebellum and Right Adrenal.

At the meeting of the Pathological Society of London on November 15, 1887 (*Lancet*, November 19, 1887), Dr. Charlewood Turner exhibited a specimen of cystic tumor of the cerebellum and right adrenal, which was taken from a man forty-four years old, who had been a policeman for ten years, and had been subjected to a good deal of knock-

ing about. Eight years before his death he was struck on his forehead with a brick. Eighteen months before his admission to the hospital, when his symptoms commenced, he began to complain of headache, referred to the occiput and forehead, accompanied with failure of sight, deafness of the right ear, and vomiting. He subsequently had incoördination of movements, with a tendency to fall to the right side. He became dull and torpid, and died in coma. At the autopsy, there was found a tumor on the right side of the cerebellum, and another on the upper surface, contiguous to the anterior part of the middle lobe, which it had compressed. The centre of each tumor was occupied by a cyst. The growth consisted of a fine reticulum, with round and elongated nuclei, traversed by a network of vessels, some of which presented varicose dilatation occupying much of the field. The right adrenal was converted into a tumor of the size of a fist, which consisted of a large cyst, surrounded by a wall of growth, having an adenoid structure resembling that in the cerebellar tumor, but more fibrous. There was also a cyst in the liver, containing clear fluid and cholesterine, and there were several cysts in the left kidney. Mr. Pye Smith has recorded a case in vol. xxxvi of the *Transactions*, in which there was a simple cyst in the cerebellum, associated with small cysts in the pancreas and kidneys.

Venesection in Sthenic Inflammations.

C. G. Wheelhouse, F. R. C. S., in the course of a lecture on the Surgical Treatment of Diseases of the Chest, which is contained in the *British Med. Journal*, November 26, 1887, says that modern physicians, in some cases at least, miss their way in the early treatment of such diseases as sthenic pleurisy, pneumonia, or acute pleuro-pneumonia, in which one good bleeding would often suffice, at the very commencement, to give command over the whole remaining course of the attack, and would often cure it altogether.

Many cases in which a patient, gasping for breath, with flushed yet livid countenance, motionless ribs, the side held as in a vice by pain, and a hard, incompressible pulse beating at 120, were in the author's experience at once restored to comfort, rest and refreshing sleep by one good bleeding, and it may be the application of a few leeches afterwards. He says he has seen the frequent repetition of this heroic measure make the last stage of a patient worse than the first; but in these days of moderation, of temperance in

all things, and of sound physiological knowledge, "we may surely learn to accept the useful, without being tempted into the dangerous portions of ancient practice."

Predisposition as a Factor in the Etiology of Facial Paralysis.

According to E. Neumann (*Arch. de Neurol.* xiv, p. 1, 1887) facial paralysis of so-called rheumatic origin depends on a "nervous" or neurasthenic diathesis. This rather novel view is defended by a series of clinical histories showing that patients with facial palsy, or their relations, present some neurosis. In one interesting observation, three of one family had paralysis, one of them having had two attacks.

New Treatment of Periuterine Inflammation by Electricity.

At the meeting of the Section on Obstetrics of the British Medical Association, held at Dublin last August, Dr. G. Apostoli, of Paris, read a paper on a new treatment of periuterine inflammation by electricity. A translation of this paper by Dr. W. Woodham Webb is published in the *British Medical Journal*, November 19, 1887. The following are the conclusions arrived at by the author:

"1. Electricity, in the form of Faradic currents of tension, can and ought to be made to calm the pain at the outset of an acute attack of perimetritis, and is a sedative of the first importance in abridging the first stage of inflammation.

"2. The continued current is a power which we use in two ways: first, in the form of intra-uterine chemical galvano-cauterization, to cut short the acute stage; second, as vaginal, negative, galvano-punctures, to get rid of the chronic condition in all its forms and stages.

"Is the restoration *ad integrum*, complete and definitive, the prevailing result of my treatment? I do not pretend that such is the case; I do not even expect it; and I content myself with offering for trial a method of relief and cure which I believe to be more speedy than others.

"Again, we may force electricity into our service in another way. Given a case of actual suppuration, or of threatening suppuration, we have only to use our negative galvano-puncture, form an eschar, open up a sinus, and direct the exit of the pus to the nearest point of the vagina. And this we can do at will, when it is most fit to do it, and in the most convenient way.

"We have, then, in the galvano-puncture an effective means of arresting an inflammation, and of dispersing an inflammatory deposit. Or, we may use it as a sure and direct way of opening a profound and ready formed collection of pus. No plan of setting up a vaginal drainage, controllable as to amount and duration, can be more simple; and this we may associate with any local and antiseptic treatment that may be desirable, as I have shown elsewhere in relation with the subject of hæmatocle.

"The subject, of which I have just jotted down the salient points for your consideration, is new and undeniably full of interest. You must not suppose that I think I have done much for it, as I may fairly claim to have done for fibromata and endometritis, but what I have seen and watched with painstaking anxiety is so rich in clinical results, so fertile in unexpected therapeutical consequences, that I feel I cannot too earnestly urge you to study the subject for yourselves, and to fathom it to the utmost, if possible."

The Value of Creolin in Surgical Practice.

The great disinfecting powers of creolin were first demonstrated by the investigations of Dr. E. von Esmarch, who showed that creolin was a more effective disinfectant than carbolic acid, or at the least was of equal value. Its germicidal powers and its antiseptic properties were tested on animals by Prof. Fröhner, who also gave it internally, and found it to be efficient against zymotic diseases of the digestive tract. The same experimenter proved that creolin is not poisonous, as animals to which he had given 750 grains of a pure preparation exhibited no disturbance of their general health. The results obtained by Fröhner induced Kartüm to experiment with creolin to determine its uses in surgical practice. From the *Deutsche Medizinisch-Zeitung*, December 5, 1887, we learn that he first used it in a severe case of puerperal fever, with extensive suppuration and ichorous infiltration of the joints. The genital organs, as well as the opened joints, were bathed with a one per cent. solution, with the immediate result that the horrible odor which stuck to all the patient's secretions and excretions was completely lost. It was next employed in the form of creolin bandages in a series of large leg ulcers, with excellent results; and, finally, in fresh cases soon after operation. In these cases iodoform and corrosive sublimate were purposely not employed, and the course of

the wound was so conspicuously favorable that the author urgently recommends a similar use of it to other surgeons. In leg ulcers the first dressing (consisting of gauze compresses, soaked in a one to two per cent. solution of creolin) was removed after four days, when a complete change was seen in the base of the ulcer. Ulcers, which before had been treated in vain with iodoform and other approved remedies, healed rapidly under creolin, with exuberant formation of granulations.

Solutions of creolin are also markedly styptic, so that the author was able to check parenchymatous hemorrhage with it very satisfactorily. As the result of his experiences with creolin, Kartüm believes that he can predict for it a prominent place among antiseptic agents; for it has both the favorable properties of iodoform and those of corrosive sublimate, without being poisonous, as these latter are. He believes that the introduction of this drug to surgical practice is a great step in advance, as it accomplishes what nothing has accomplished heretofore, being non-poisonous, disinfectant, capable of checking secretion, favoring the formation of granulations, and styptic to a certain degree.

Abscess of the Lung, Probably Caused by the Stump of a Tooth Passing into Right Bronchus.

Dr. William Stranger, senior physician to the Worcester General Infirmary, reports the following interesting case in the *Brit. Med. Journal*, November 26, 1887:

E. M., a robust young woman, 23 years old, with well-developed chest and fine physique, and in good health, although in infancy she had been the subject of scrofulous abscesses of the hands and feet, took chloroform, for the extraction of several stumps of teeth, on February 17, 1887. A few days afterwards a troublesome irritative cough came on, with slight muco-purulent expectoration. This condition continued until the month of June—four months. During this time she was never entirely laid up, although frequently confined to her bed for two or three days; nor did she lose very much flesh or appetite. The cough continued to annoy her greatly; the expectoration increased, and the strength began to fail. She was first seen by him as an out-patient at the Infirmary on June 8, and on June 15 her case appeared to be so serious that she was placed under treatment in a private house.

There was almost incessant cough, preventing any sleep, except by the use of nar-

cotics; large muco-purulent expectoration, which was very offensive; coarse *râles* over a large area of the centre of the right lung, extending from the upper third of the scapula down to the ninth rib vertically, and from close to the spine to just above the nipple transversely. In front, there was great tenderness over the third, fourth, and fifth ribs, but no pointing or bulging of the intercostal spaces. Over the other parts of the lung respiration was free and normal, with the exception of some dulness at the base. The left lung was rather hyper-resonant. The paroxysms of coughing continued unceasingly for several hours at a time, almost abolishing sleep. There was not very much loss of flesh; the appetite was good; the pulse 110; temperature 102° F.

From the account given by a young friend who accompanied the patient to the dentist, it appeared very probable that a stump had escaped the operator, and had passed down the trachea into the right bronchus. This idea was confirmed by the friend stating that there was great searching of the mouth for a stump, and some alarm expressed. Further, she stated that before the patient came to the Infirmary, rings of cartilage, showing necrosis, were found in the sputum, which was horribly offensive. From June 15 to July 18, the case continued to increase in severity and urgency. The cough was almost incessant; bad bedsores formed from the continuous sitting posture; the temperature, however, only varied between 101.4° and 99°, and was often normal.

The pulse on June 16 was 146, on the 19th, 160, then it fell gradually to 120 on the 26th, again rose to 140 or more, and finally dropped, under large doses of brandy, to 120, where it remained until July 18, the thirty-third day of treatment, and five months from the date of the tooth drawing. During the whole of this time hectic fever continued to consume the patient's strength. The expectoration was putrid to the last degree, the room, and also the house itself, being only rendered bearable by chlorine gas freely used, with deodorants to the sputum. For some time past the sputum had contained a large quantity of broken down pulmonary tissue which settled in quantities to the bottom of the vessel. From two to three pints of this stinking stuff were expectorated daily. Occasionally it ran in a stream from the patient's mouth, and this caused a very tiresome aphthous condition. Large amphoric breathing with metallic tinkling was now heard in the centre of the lung over a space of over four inches square.

Having now, on July 18, five months from the access of cough, to deal with a gangrenous abscess of very large dimensions, with continuous destruction of lung tissue, which abscess had certainly existed for thirty-four days, if not longer, Dr. Stranger came to the conclusion that nothing but puncture of the lung, reaching the abscess, and draining it, would give the patient any chance of surviving, even for a few days.

On July 18, the operation was performed. The needle of an aspirator was pushed quite home into the chest, just below the ninth rib, and at one inch behind the axillary line. A drop of pus appeared almost at once. Free vent was given to the pus, and a drainage tube inserted, the wound being dressed antiseptically. Recovery was slow, but by October 29, the patient had gained fourteen pounds in weight, and all signs of the immense abscess and its cavity had disappeared.

The Part played by the Nose and the Anterior Respiratory Passages in Respiration.

R. Kayser reports in *Pflüger's Archiv* some investigations upon the part played by the nasal cavities in the warming and vaporization of the inspired air. In these he differs from the results obtained by Aschenbrandt. From the *Centralblatt f. d. med. Wissensch.*, November 5, 1887, we learn that Kayser regards as incorrect the assertion that a vital rôle attaches to nasal respirations, which cannot be accomplished by mouth and throat breathing. By means of a series of experiments, similar to those employed by Aschenbrandt, he established the most essential results of the latter's researches. He finds that air passing through both nasal cavities (five liters in 30 seconds), when the temperature of the outside air is from 50°-54° F., is warmed to about 88° F., and is completely saturated with vapor; and this occurred although he was careful to hermetically seal the nasal cavities by firm pressure of the palate against the posterior nasal fossæ.

This result is not changed if the rapidity of the current of air is increased upon both sides. If the temperature of the outside air is lower, the degree of warming obtained is less, but is always decided; air at a temperature of 32°-39° F. is warmed to a temperature of 81.5° F. If the experiment is so conducted that the current of air, instead of passing through the nose, passes through the mouth and throat, then the degree of warming obtained is only slightly less, while the saturation with moisture is just as complete. The author also thinks that the deeper respiratory passages must play a rôle similar to that of

the nose or mouth and throat, if the air which reaches them is not already warm and moist. But in normal nasal breathing, the greater part of the work devolves upon the nasal cavities.

The opinion of Aschenbrandt with reference to the purification of the air from dust as it passes through the nose, Kayser does not find verified in his own experiments. He thinks, moreover, that a certain quantity of particles of dust must penetrate even into the lungs.

Foreign Body in the Right Bronchus; Tracheotomy; Recovery.

R. M. Simon, assistant physician to the General Hospital, Birmingham, reports the following case in the *British Med. Journal*, November 26, 1887:

A boy, six years old, was admitted on the night of Tuesday, October 11, suffering from cough, and with a history of one attack of very urgent dyspnoea. It appeared that on the preceding Sunday he had been unwell and had a cough. He was well enough to go to school on Monday, but in the afternoon, whilst hanging up his cap, he swallowed a damson stone, which he had in his mouth since dinner. A violent attack of choking came on, and he was sent home. A medical man was called in, but, though he passed an œsophageal bougie, he was unable to find the stone. The patient remained at home pretty well until late on Tuesday night, when, his breathing having become stridulous, and a bad attack of dyspnoea having occurred, he was brought to the hospital.

On admission he was found to be suffering from occasional cough. His voice was stridulous and his breathing noisy. Beyond slight impairment of resonance at the right base and a few coarse bronchial râles, nothing was revealed by physical examination. He remained pretty much in the same condition until the next morning, when there was very complete dulness at the right base, and a total absence of breath sounds over the same area. He had had only one slight attack of dyspnoea since admission. It was thought that he was suffering from collapse of the lower portion of the right lung, owing to the impaction of the damson stone in the lower division of the right bronchus. At 4 P.M. he had a most violent attack of dyspnoea, which lasted about six minutes. He became black in the face, and was very much distressed. At 5.30 P.M. there was found evidence of œdema of the left lung, in addition to the signs of collapse at the right base. It was thought inadvisable to defer operation, and tracheotomy was at once

performed. Nothing was to be seen, but the introduction of an oiled feather was followed by a violent expiratory effort and the expulsion of the stone. Owing to the accompanying laryngeal catarrh it was decided to leave a tracheotomy tube in. The boy's condition at once improved, and next morning, when the tube was removed, he was quite comfortable. Air entered the right base freely, and all dulness had disappeared. There remained only slight evidence of catarrh, and in a fortnight he was sent out quite well.

The author remarks with reference to this case that diagnosis of impaction of the stone in the right bronchus was rendered easy by the signs of collapse of the base of the right lung, and the only question to be considered was that of operation—whether it was wiser to operate at once or to wait. Most of the published cases record operations months after the accident, with at times good results, but more often with bad, owing to destructive changes in the lung. Many cases are recorded in which the foreign body has been expelled during a fit of coughing. In this case it was judged wise not to defer the operation, owing to the rapid changes in the lung; and it is noteworthy how quickly the lung recovered itself after the stone was removed. No doubt the attacks of dyspnoea were occasioned by coughing up the stone to the glottis. Had the boy been older, it might have been advisable to have inverted him, but the difficulty of teaching so young a child to take a deep inspiration at the moment of inversion was an obstacle to this procedure. In any case it seems the best plan to perform the harmless operation of tracheotomy at once, rather than to wait until the foreign body is imbedded in mucus and fixed by inflammatory exudation.

Statistics of the Results of Intubation of the Larynx.

In the *British Medical Journal*, November 19, 1887, Dr. C. J. Symonds, Surgeon in charge of the Throat Department of Guy's Hospital, London, after a brief summary of the history of the operation and its dangers, gives the following statistical statement of its results:

Dr. Ingals has collected 514 cases, with 134 recoveries, or 26.7 per cent. The greater number of these cases occurred in his own practice and in that of O'Dwyer and Waxham, all skilled operators. Dr. Waxham reports 136 cases of his own, with 37 recoveries, of 27.2 per cent.; and of these 72 were three years of age or under, with 16 recoveries, or 22 per cent., the youngest to recover being

nine months; 64 were over three years, and of these 21 recovered, or 32.8 per cent. It is stated that in every case membrane was observed before operation, and it is clear from the reports of the cases that in the vast majority death would have speedily occurred had not the operation been performed. The suggestion, therefore, that the success is due to early operation must, in the face of the reports, be silenced. Dr. Waxham concludes that 25 per cent. will be saved, and that, for his part, he will never perform tracheotomy again. So great a measure of success has not attended the practice of others. Thus Dr. Strong, in the discussion on Dr. Waxham's paper, reported 32 cases, with 31 deaths, the fatal issue being attributed to traumatic pneumonia, extension of membrane, and actual starvation. Another speaker, Dr. Hatfield, recorded 10 cases, all fatal. If the results obtained by Ingals and Waxham are contrasted with tracheotomy, the new operation stands first as a means of saving life. Tracheotomy under four is admitted to be, on the whole, successful. Dr. Ingals estimates the recoveries at 15 to 20 per cent.; Trousseau for all cases, 20 per cent., or 1 in 5. Individual operators can, no doubt, show better results than these; thus Dr. Mudd, in contrasting intubation and tracheotomy, gives as occurring in his own practice and in that of his firm 171 cases, with 46 recoveries, or 26.9 per cent. His later cases did better, for out of the last 32 no fewer than 16 recovered. This success he attributes to the milder character of the disease, and to the fact that the operation was performed earlier. Those who see much of tracheotomy know well how the results vary with the character of the disease, and the same influences act, of course, for or against intubation.

Dr. Symonds states that he remembers a series of 19 tracheotomies at Guy's hospital with 1 death, followed by another series in which they nearly all died.

An Epidemic of Typhoid Fever Traced to a Dairy.

Ali-Cohen, in a communication to the *Weekbl. van het Nedrl. Tijdschr. voor Geneeskunde*, reports 63 cases of typhoid disease which came under his observation during three months in Groningen. From the *Centralblatt f. d. med. Wissensch.*, November 5, 1887, it is learned that, two months before the outbreak of the epidemic, there were some mild cases of typhoid fever in a dairy which was situated in the suburbs of the city. In the yard of this dairy was found a large dung-heap, which was en-

tirely uncovered; the well lay close to the cess-pool. The dejecta of the patients were brought to the dung-heap or to the cess-pool. All the water which was used was drawn from that well. Of 58 patients who lived in different parts of the city, 43 obtained their milk from this dairy, and three used water from the well; 10 had used neither; while in two it was uncertain whether the milk or the water had been used or not. Without counting five patients at the dairy itself, about 80 per cent. of the cases were traceable to this source of infection. Of 43 persons who had used the milk, 23 drank it without having boiled it, 14 boiled it, and 3 used it with coffee. Moreover, in many houses in the city there were cases of typhoid affecting those who obtained their milk from that dairy, while others, who lived in the same house, but obtained their milk from other places, were not taken sick. The very same thing was noticed with regard to people living in the same house, some of whom took water from the infected well and others did not; those who did not remained healthy. A chemical examination of the well-water gave the following result: Reaction, neutral; no ammonia or hyponitrous acid; traces of nitric acid, much sulphuric acid (about 149.1 mgrm. per litre); organic matters, 25.1 mgrm. The investigation of the water for typhoid bacilli did not establish their presence; possibly because the methods used were imperfect, or because of the late time at which the investigation was undertaken. Nevertheless, the common infection through the milk is in this instance to be regarded as positively proved, as the 43 patients, who were scattered all over the city, had nothing in common except that they were exposed to the same injurious influence in drinking the milk.

Etiology of the Acute Nephritis of Childhood.

In the *Charité Annalen*, xii, 1887, S. 638, E. Henock has a paper upon the affections of the kidney in childhood. From a review of this paper in the *Centralblatt f. d. Med. Wissensch*, November 5, 1887, we abstract those parts of it which refer to the etiology of acute nephritis.

Acute nephritis of children, says Henock, as every one knows, is in the vast majority of cases the result or the attending symptom of an infectious disease; nevertheless it is an undoubted fact, that children may acquire acute nephritis without having passed through an infectious disease, but from the application to the skin of certain substances,

such as balsam of Peru, carbolic acid, and tar. Examples of nephritis arising in this way have been previously reported by the author; to these he now adds two new observations. In the latter, two children, seven and eight years of age, respectively, had been treated at the Charité for itch withunctions of balsam of Peru, and were taken sick with acute nephritis in immediate connection with this treatment. Both cases resulted in recovery. Henock also thinks, as a result of his experience, that cold, either in the form of sudden drenching, or a more continuous and persistent action of the cold, is a more frequent cause of this disease than is commonly supposed. The combination of inflammatory diseases of the air passages with acute nephritis, with complete integrity of other organs, which Henock has frequently observed, he regards as further testimony to the connection existing between cold and acute nephritis. As proof of this assertion, he reports four pretty decided cases, in which the disease was introduced by a more or less diffuse bronchial catarrh, and at the time the patients were admitted to the hospital, all the symptoms of broncho-pneumonia; while the nephritis, as was proved with certainty, did not develop itself until some time later. The nephritis, he says, cannot be regarded as the cause of the bronchial affection, but both the latter and the former are to be referred to one and the same cause, namely, cold. In a fifth case, a girl nine years old was taken sick, immediately after a severe chilling, with purpura rheumatica, to which an acute nephritis was soon added. There remain, however, a number of cases in which cold as the etiological factor of the nephritis is as good as excluded, and in which the mode of origin of the disease is completely shrouded in obscurity. In a case of this kind affecting a boy ten years old, who was carefully guarded in bed during convalescence from a perityphlitis, nephritis suddenly developed. Before its onset the urine had been often examined, but never contained any albumin.

—In New York, Dr. Edson, of the Health Department, vaccinated sixty tramps at the 4th District Station House, on the night of December 7. The story of this achievement is graphically told by a New York daily paper; which also gives a thrilling account of the way in which Dr. John T. Nagle photographed a group of the tramps by the flash of a pistol loaded with gun-cotton and magnesium.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, -	6.00
Physician's Daily Pocket Record, -	1.25
Reporter and Pocket Record, -	6.00
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 10,250 copies.

CLOSE OF VOLUME FIFTY-SEVEN.

The present number concludes the fifty-seventh volume of the REPORTER, and precedes its entrance upon the thirty-sixth year of publication. This long career has been marked with so many evidences of appreciation from the medical profession that its vicissitudes, as they recede in the distance, seem less like actual experiences than like the productions of a dream.

It is true the trials of the current year, the embarrassments inseparable from a change of management, the experiences of illness for one editor and of sudden death for the other, are too near to be indistinct. Still, the last six months have seen, we trust, no diminution in the vigor of the REPORTER, no wavering from the principles which its present managers believe to be calculated to increase its usefulness and prosperity. The experiences of the past eight months justify the expectation that the next year will be one of advance and improvement; and we enter upon it hopefully,

wishing to all our friends "A happy New-Year!"

GERMS AND PERITONITIS.

Nothing has contributed more to our knowledge of the relative influence of chemical irritants and micro-organisms upon the human economy than experiments conducted upon the peritoneum. The whole question of the etiological importance of the tubercle bacillus may be said to rest upon the results of investigations in regard to its action upon the peritoneum, and in the vitreous humor of the eye. So it is interesting to observe a new set of experiments made by Pawlowsky upon the action on the peritoneum of the chemical constituents of the contents of the intestines, and of certain microbes. In conducting these experiments Pawlowsky injected into the peritoneal cavity of rabbits a variety of substances. His first set of experiments was made with croton oil, which, in all but very small quantities, produced an acute hemorrhagic peritonitis. He next tried the effect of solutions of a digestive ferment: trypsin. This was found to be in the highest degree irritating, causing a severe hemorrhagic peritonitis, and death within a few hours. This was accompanied with marked evidences of constitutional disturbance: the hairs of the animals experimented upon were loosened, and rubbed off easily; their skin was roughened; and the epithelial layer of the peritoneum came off in large flakes. Microscopical examination of the peritoneum showed that in these experiments there were no bacteria present.

In another series of experiments Pawlowsky investigated the action of microbes pure and simple. The first experiments were made with a cultivated microbe, derived from human pus, which was at first taken for the staphylococcus albus. This, even when mixed with a small quantity of croton oil, did not cause the death of the animals. The same was found to be true in regard to sarcina; so that Pawlowsky concludes that non-pathogenic micro-organisms, even when mixed with small quantities of a chemical irritant, are not capable of producing peritonitis.

His conclusions in regard to pathogenic micro-organisms are altogether different. His experiments with these microbes were first made with cultivated staphylococcus aureus, derived from an acute osteomyelitis. When this was injected into the peritoneal cavity, in all but the most infinitesimal quantities, it produced intense fibrino-purulent peritonitis. Microscopical investigation showed that the microbes had increased rapidly in the peritoneum; and they were also found in the lymph spaces of the central tendon of the diaphragm, in the anterior wall of the abdomen, and in the capsule, the trabeculae and the peripheral layers of the pulp of the spleen.

The next line of investigation taken up by Pawlowsky was to ascertain the influence of the different parts of the contents of the bowels in producing peritonitis. He first injected into the peritoneal cavity of rabbits the unmixed contents of the intestine of a healthy and recently killed rabbit. This caused the death of the four rabbits experimented upon from purulent peritonitis. He next used the liquid obtained from the same material by filtration; and the animals so experiment on survived (*genasen*). Likewise did a rabbit injected with bowel-contents after sterilization for eight days by Tyndall's method; although in this case the autopsy disclosed the fact that particles of the bowel-contents were lodged upon the peritoneum and covered by a fibrinous layer, and the presence of a peculiar bacillus, which Pawlowsky describes. Cultures of this bacillus produced peritonitis in other rabbits.

The final conclusions of Pawlowsky are: first, that chemical irritants, in sufficient quantity, excite a hemorrhagic peritonitis; second, infection with microbes may produce an intense and rapidly fatal peritonitis without marked macroscopic signs, a fact which may explain the occurrence of fatal peritonitis, without demonstrable lesions, in human beings; third, intense infection with microbes produces a hemorrhagic peritonitis; fourth, a less overwhelming infection produces a fibrino-purulent peritonitis; fifth, when the infection is not so severe, or when the animal

survives a long time, the peritonitis is of a purulent character; sixth, free secretion of fibrin is the means adopted by the peritoneum to protect itself.

We have not laid these interesting facts before our readers merely because they are interesting; but rather because they have a most important bearing upon the beliefs and practice of every medical man. They seem to establish the fact that, of all the ingredients of the intestinal tract, the most dangerous, when they come in contact with the peritoneum, are the micro-organisms; and they justify the practice of modern surgery in endeavoring to exclude from the peritoneum the baneful influences of these micro-organisms, by excluding the micro-organisms themselves, or by rendering them innocuous by suitable chemical antidotes. These experiments have also an important bearing upon the question of the so-called germ-theory of disease; and, so far as the peritoneum is concerned, they seem to demonstrate the fact that the most dangerous and most rapidly fatal forms of peritonitis are those which depend for their intensity upon the presence of microbes; so that, for peritonitis, we may consider the germ theory to be pretty well established.

QUACK ADVERTISEMENTS IN RELIGIOUS NEWSPAPERS.

From time to time medical men and medical journals have protested against the prostitution of the columns of religious newspapers to the use of advertisers of quack nostrums. This protest does not apply to temperately worded representations of what seems to have been accomplished by, or what may reasonably be expected of, a remedy or device for the cure of disease or injury. But it does apply to advertisements couched in language which bears the stamp of falsehood on its face, or which is of such a character as to arouse suspicion in the mind of an intelligent man, uninfluenced by a money consideration.

The editors of most religious journals are, as a rule, men of so much intelligence that they will hardly attribute to trade-jealousy alone the objection which medical men have

to the recommendation of "sure cures" for baldness, fits, rupture, consumption, and so on, to persons who are apt to regard their religious teachers as safe guides in matters of health or disease; and who are not sufficiently familiar with the subtleties of the newspaper business to distinguish between the responsibilities of the editor and those of the publisher. As a fact most readers of periodicals have the impression that the advertisements they contain are endorsed by the editor. Advertisers rely upon this fact; and we cannot understand the casuistry which satisfies the conscience of a man who edits a periodical, ostensibly devoted to religion, which replenishes its coffers with the price of palpable falsehoods.

If it were true that a religious paper could not be financially successful without taking money for the advertisement of worthless or delusive remedies, a course might be suggested worthy of the main object of these papers. But it is not true; for there are a few happy illustrations of the fact that, even in a religious newspaper, "honesty is the best policy."

We call the attention of our large circle of readers to this matter, in the hope that they will use their influence to put an end to what we regard as a serious blemish in religious newspapers, and one which injures the good reputation which they ought to enjoy. And we call the attention of those religious newspapers to which our remarks may apply to this matter, in the hope that we shall not have to recur to it in a more explicit manner.

A SECRET OF SUCCESS.

In an interesting paper read before the New Hampshire Medical Society, this year, Dr. W. S. Leonard points out a number of reasons why the laity come to trust in the virtues of non-professional prescriptions, and neglect to seek the advice of their physicians. One of these reasons, to which attention may be profitably called, is the habit many medical men have of treating slight ailments slightly. This habit is often strongest in the ablest practitioners, who conscientiously believe that it is only honest to show a patient with a trivial ailment that it is

trivial. But we believe that it is rarely a good service to do this. As the physician's object is to cure, he must study what course is best adapted to this end; and if this be to keep to himself the belief that his patient is exaggerating the importance of his trouble, it is neither kind, nor especially virtuous, to disclose his opinion. This is a very different thing from practicing upon, and increasing, a patient's fears—the refuge of none but dishonorable men. It is simply showing proper consideration for the state of mind in which the patient is, and securing his harmonious coöperation in the work of cure.

An extreme of candor is harmful in many cases, as it rarely leads the patient to distrust his own opinion, and rarely raises his appreciation of the doctor's. More than this, the habit of treating hastily or superficially ailments which, to the physician, seem of little consequence, often leads patients to think that the physician despises cases which do not call for the greatest skill, or present features of rare interest. Dr. Leonard quotes a man with a lame knee, who came to an old physician whom he had tried in vain to interest in his case, and said: "Doctor, a man must come to you with his shroud in his hand, before you will do anything for him."

When the community thinks thus of a physician, his usefulness, as well as his prosperity, is in imminent danger. Both these are proper objects of solicitude for the right-minded physician; and for the sake of both he should not despise the lesser ills of his patients, remembering—besides the fact that what seems trifling may really be serious—that no ill seems small to the one who bears it, and that an honest and kindly sympathy for small ailments and little anxieties is the mark of a large heart and a wise head.

—A Congress of Physicians and Veterinary Surgeons, having for its object the scientific study of tuberculosis in man and the lower animals, will be held at Paris from July 25 to August 31, 1888. Any physician or veterinary surgeon may become a member of the Congress by enrolling his name and paying an assessment of ten francs (about two dollars). More complete details of the Congress will be published later.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

A TEXT BOOK OF ORGANIC MATERIA MEDICA OF THE BRITISH PHARMACOPŒIA, ETC. By ROBERT BENTLEY, M.R.C.S. Eng., F.L.S., etc. 8vo, pp. xxviii, 415. London and New York: Longmans, Green & Co., 1887. Price, \$2.50.

This book is very like that of Dr. Maisch, which we reviewed in the REPORTER, Nov. 19, 1887, and very much the same comments apply to it. It is admirably prepared, containing in concise sections a description of all the vegetable and animal parts or products which are included in the British Pharmacopœia, their sources, preparations, uses and dosage. It is handsomely illustrated, and clearly printed, and altogether a book creditable to the publisher as well as to the author.

ANNUAL REPORT OF THE SUPERVISING-SURGEON-GENERAL OF THE MARINE HOSPITAL SERVICE OF THE UNITED STATES FOR THE FISCAL YEAR 1887. 8vo, pp. 308. Washington: Government Printing Office, 1887.

This volume contains a large amount of tabulated statistics of disease and injury coming under the care of medical officers belonging to the Marine Hospital Service. These statistics are for the most part well tabulated; but it would be an improvement if the varieties in each supervision were arranged in alphabetical order. Nearly 200 pages of this Report are occupied by accounts of cases selected from hospital practice, many of them of great interest. Those in which the blood-vessel system was involved are of especial value, and include no less than eleven cases of aneurism of the aorta.

We would recommend our readers to apply to Surgeon-General Hamilton for a copy of this useful Report, for it contains much matter which deserves wide reading.

DE L'ÉTAT DE LA DENTITION CHEZ LES ENFANTS IDIOTS ET ARRIÈRÉS. Par ALICE SOLLIER, née MATHIEU-DUBOIS, Docteur en Médecine, etc. 8vo, pp. 179. Paris: Aux Bureaux du Progrès Médical, 1887. Price, 4 francs.

The author of this book is a woman, who, in her preface, testifies to the kindness with which she has been treated by the Faculty in Paris during the course of her medical studies; and in her book demonstrates what good results may be secured by an earnest and conscientious use of opportunities which present themselves to all who truly seek them. She has taken up a study in which Bourneville and Magitot have already engaged, and has gathered some very interesting facts in regard to the process of dentition in idiots and children with retarded development. Her investigations demonstrate that anomalies and lesions of the teeth are found in 91 per cent. of all idiots, and that these anomalies and lesions affect almost exclusively the second dentition. She finds also that about half (45 per cent.) of the cases she studied had defects of the vault of the palate.

For other details of this interesting study, we must refer our readers to the book itself, which is well written, well printed and admirably illustrated.

PAMPHLETS.

THE USE OF ADHESIVE PLASTER IN ORTHOPÆDIC SURGERY. By A. B. JUDSON, M.D. From the *New York Medical Journal*, June 4, 1887. 12 pp.

HAY-FEVER. THE PRIZE-ESSAY OF THE UNITED STATES HAY-FEVER ASSOCIATION FOR 1887. By SETH S. BISHOP, M.D. From the *Journal of the American Medical Association*, July 23, 1887. 40 pp.

THE ANATOMY AND PHYSIOLOGY OF THE RECURRENT LARYNGEAL NERVES. By FRANK H. HOOPER, M.D. From the *New York Medical Journal*, July 9, 16, 23, and August 6, 1887. 40 pp.

ILLUSTRATIONS OF VIVISECTION. By MISS FRANCES POWER COBBE. Philadelphia: American Soc. for the Restriction of Vivisection, 1887. 23 pp.

—Dr. Judson's pamphlet contains an excellent description of the uses to which adhesive plaster can be put in the correction of deformities, and the way in which it can best be used. With this, is a very interesting history of the subject.

—Dr. Bishop believes that hay-fever is a functional nervous disease. This theory is not incompatible with the fact that a diseased membrane may be found in the nose after many recurrences of congestion in years of suffering. The remedies he suggests are chiefly nervines and general tonics. Quinine, he believes, is both palliative and, in a sense, curative. The best treatment consists in the administration of from $\frac{1}{2}$ – $\frac{1}{4}$ gr. of morphia, with from $\frac{1}{300}$ – $\frac{1}{100}$ gr. of atropia. Of operative treatment he does not appear to think very highly.

—The anatomy and physiology of the recurrent laryngeal nerves furnish a wide field for discussion, and one which has of late attracted considerable attention. Dr. Hooper has studied the subject very thoroughly, both in medical literature, and by experimentation. He concludes that these nerves are purely motor in function; that their action on the glottis is different, in different animals; in the dog they close, in the cat they open the glottis. In the human subject, the evidence seems to indicate that stimulation of the recurrent laryngeal nerves causes widening of the chink of the glottis. An important conclusion of Dr. Hooper is that ether-narcosis abolishes the function of the glottis-closers. In this, he opposes the view expressed by Dr. F. Donaldson, Jr., in the *American Journal of the Medical Sciences*, July, 1886.

—Miss Cobbe's pamphlet contains a number of illustrations copied from various works on physiology, showing the appearance of animals undergoing experimental vivisection. The object of the pamphlet is to excite repugnance to a method of study which involves the infliction of pain upon the subjects of experimentation. Those who are opposed to this method hold that its advantages are not commensurate with the hardships it entails upon defenceless beings; and Miss Cobbe is one of the most earnest and uncompromising of its opponents.

LITERARY NOTES AND QUERIES.

[In this column the REPORTER will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—After January 1, 1888, the *Journal of Reconstructions*, published by Reed & Carnrick, will be published under the title of the *Dietetic Gazette*. Dr. Geo. B. Fowler will be the editor; and the journal will be increased in size by the addition of eight pages.

NEW INSTRUMENTS.

THE JONES-MARTIN SPECULUM.

The speculum invented and used by Dr. August Martin, of Berlin, has been highly praised and much used in this country. Its blade is short and wide, and its handle of a size and shape which enables the assistant to hold it in position without being in the way; and it gives the operator the best possible view of the field of operation. But with the Martin speculum, irrigation, which is often required in operations within the vagina, is apt to cause a good deal of wetting of the patient, of the operator, and of his assistant. But the Jones-Martin speculum, made by Codman & Shurtleff, of Boston, has the advantages of construction found in the original, with the improvement of having the handle made of a tube, with a hook at the end, on which a small pail may be hung to catch the drainage. This makes the operation more cleanly; and the weight of water furnishes a certain amount of traction, and holds the speculum in place without an assistant.

CORRESPONDENCE.

Twins: One Black and One White.

EDS. MED. AND SURG. REPORTER:

Sirs:—A very interesting case has occurred in my practice which I desire to report, thinking probably it would be interesting to the readers of this journal.

Case.—A black negro girl about eighteen years old gave birth to twins at seven months, one of which was as black as the *ace of spades*, and the other as white as any white child I ever saw. This girl has been engaged as nurse in a white family a part of the year, but she has associated with both white and black. Both cords were attached to same placenta. Is this merely a freak of nature, or is it possible that they have different fathers? I would like to have the opinion of some of the brethren.

NEWTON HILL, M.D.

Pickensville, Pickens Co., Ala., Dec. 5, 1887.

Very Early Menstruation.

EDS. MED. AND SURG. REPORTER:

Sirs:—Recently I came across a case of early menstruation which I consider rare. It is very interesting to me: and, thinking it might interest other members of the profession, I will report it to the readers of the REPORTER.

Ellen B——, American born, but of German parents residing in this city, 11 years old, weight 120 pounds, began menstruating when sixteen months old, and has continued to do so regularly every month up to present time. The flow formerly lasted from two to four days, but of late it lasts from five to seven days. The mammæ are much larger than they should be at her age, but not as large as in adult women. There is no growth of hair on the pubes. The girl is physically strong and healthy; she is not tall, but has large bones, and is plump and heavily built. Mentally she is weak, or deficient. Her parents say her memory is not good, and she cannot learn at school as other children do. The parents are honest, reliable, well-to-do people, having had a family of eight children—five girls living, older than this one, all apparently healthy; and two boys living and healthy.

I can give full credit to all they say of the past, and I have examined the child for the present myself.

S. P. BARNES, M.D.

Massillon, Ohio, Dec. 8, 1887.

Clinical Reading.

EDS. MED. AND SURG. REPORTER:

Sirs:—Find enclosed \$5.00 for my subscription for the MEDICAL AND SURGICAL REPORTER for the coming year. This is the twenty-second year that I have taken the REPORTER. Keep on improving the REPORTER; put in all the clinical reading you can.

Yours truly,

S. A. BENNETT, M.D.

New Portland, Me., Dec. 7, 1887.

[In reply to this pleasant note, we would say that we appreciate the desire of our subscribers to have practical subjects discussed in the REPORTER, and especially clinical notes and lectures. Having this in view, we have just completed arrangements to furnish during the coming year clinical reports and hospital notes of the greatest value, and hope to make this department a distinguishing feature of the REPORTER.—EDS. REPORTER.]

NOTES AND COMMENTS.

Two Cases of Poisoning with Nutmegs.

Dr. W. T. Dodge, of Marlette, Mich., in a letter to the *Med. Record*, November 12, 1887, says, that in June, 1886, he was called to see two children, a girl about four years of age, and a boy about eight, who had been left at a farm-house alone all day, and were discovered acting strangely on the return of the family in the evening. An investigation discovered pieces of nutmegs about the house, and the little girl stated that she had eaten one, but had vomited, and that the boy had eaten two. The latter soon becoming stupid, his parents became alarmed and sent for Dr. Dodge, who found him in a semi-comatose condition, and immediately administered an emetic and diffusible stimulants. Vomiting was free, but the coma increased until it was soon impossible to give him anything by the mouth. Hypodermic injections of brandy, ammonia, and small doses of sulphate of atropia were given, and artificial respiration was continued all night, but the little fellow did not rally, and died at an early hour the following morning. There was complete suppression of urine. The little girl became partially unconscious about two hours after the boy was taken, but could be at all times easily aroused and was all right in the morning. It will be seen that the symptoms were similar to those of opium poisoning, but there was no opium in the house, and there appears to be no doubt that the death of one child and the symptoms shown by the other were caused by eating the nutmegs. Probably both children would have died had not the little girl vomited soon after eating her share of the nutmegs.

Ligature of the Clitoris in a Young Child.

Dr. George F. Wilson, Assistant Surgeon, United States Army, of Fort Shaw, Mon. Ter., says in a communication to the *Med. Record*, November 12, 1887, that on the morning of August 29, 1887, he was called to go a distance of about twelve miles from Fort Shaw to see a girl six years of age, who had been taken seriously ill on the previous evening. He was informed that the child had been put to bed at its usual time, in good health apparently, and about ten o'clock it began to cry out with pain. The parents then examined the child to find the source of the trouble, and discovered that something was protruding from her vagina. On arriving at the house Dr. Wilson asked to see

the patient immediately, as the mental distress of the parents rendered their account still more bewildering. The patient, a thin and poorly-nourished girl, was lying on the bed, her clothes completely saturated with sweet oil, urine, and the water from many hop poultices, which had been constantly applied since the discovery of the trouble. Just above the meatus, and occupying the site of the clitoris, was a small, tense, œdematous swelling, about the size of a marble, and separated from the normal parts by a deep sulcus. As every attempt to examine the lump was met by struggles and screams on the part of the patient, and cries of despair from the parents, Dr. Wilson was obliged to administer a small quantity of ether. When partially under the influence of the anæsthetic the child voided her urine, which operation caused the lump to move about as if lightly suspended, at the same time bringing into occasional view the orifice of the meatus, which was to no extent involved in the swelling. As soon as the patient became quiet the mass was examined, and two small ends of thread were seen projecting from the sulcus, anteriorly. Traction on each separately, failed to loosen them, so it was then concluded that they must be the ends of an encircling ligature. Acting on this supposition the tumor was squeezed between the thumb and fingers, which relieved much of the tension, so that the bottom of the sulcus became visible. A thread was then discovered and cut with scissors, after which gentle pressure with the fingers restored the parts almost to the normal, to the very great joy of both parents. As the only other member of the family is a child about three years of age, it is probable that the girl must have tied the string herself. The sex, extreme youth, and undeveloped condition of the parts are the unusual features of the case.

Bantock on Listerism.

The *Glasgow Med. Journal* says that in a paper read before the British Gynæcological Society, 26th January, 1887, Dr. Bantock ventured to predict the future of Listerism in the following words: "Finally, gentlemen, what is to be the future of this system? Shall I play the rôle of prophet, and attempt to forecast its future? The old adage forbids. Perhaps, ere many years have gone over our heads, Listerism will already have become a thing of the past and as a tale that is told; perhaps the men of even the next generation, in the course of their study of this subject as matter of 'ancient history,' will be heard

asking of each other the question. 'What was it all about?' And perhaps it will be chronicled as one of the crazes to which, to our humiliation be it said, our profession has been given up soul and body. And as we now smile at the doctrines of the rationalists and the empiricists, of the dogmatists and the methodici, as we are lost in wonder and amazement at the belief in charms and amulets, and in the efficacy of the royal touch, and as we ridicule the vagaries of the alchemists and the astrologers, of the mesmerists and the healers by faith and prayer, as well as the antics of the African medicine man, so will our sons, perhaps, smile at the credulity of their fathers, and wonder at their unreasoning faith in the virtues of a practice which 'was based upon a hypothesis that was not proven,' and certainly was 'not true.'"

Emulsion of Castor Oil.

Ol. amygd. dulc.....	f. xx
Ol. ricini Ital.....	f. iv
Aq. rosæ.....	f. vj
Liq. ammon. B.P.....	f. j

Mix liq. ammon. and water; add gradually, with shaking, to the oils previously mixed. Scent with essence of bergamot, f. ij, or according to common sense (if any present). It will not separate for years if carefully mixed.—*Chemist and Druggist*, Nov. 26, 1887.

Antipyrin and Antifebrin in Hay Fever.

Dr. W. Cheatham, of Louisville, Ky., in a letter to the *Medical Record*, October 8, 1887, says that he used antipyrin for hay fever frequently during the summer and autumn of 1886, and always with the best results. During the summer of 1887 he tried both antipyrin and antifebrin for this affection. He then reports the following case:

"Mr. B——, foreman in a large railroad repair-shop, has had so-called hay fever for ten years; the difficulty begins with him in early spring, and ends with cold weather. He has taken, during the whole summer, a daily dose of fifteen grains of antipyrin, which has given him great comfort, relieving him entirely of all the fever symptoms, stimulating him for work, giving him good rest at night, and lessening very much all nose and eye symptoms."

Dr. Cheatham says that he used it in the summer of 1886 in fourteen other cases, with similar results. During the past summer he has tried the antifebrin in half of his cases. The effect has been about the same as that obtained from antipyrin. In a few of the cases some slight depression was complained

of, but this is readily corrected by small doses of belladonna or its alkaloid. Some of his patients have taken both the antipyrin or antifebrin (more frequently the former) daily—from ten to thirty grains of the former, or from four to six grains of the latter—for several months, with no bad effects. He believes it to be of great benefit in hay fever, and is anxious for others to try it.

Spurious Hydrophobia.

On November 29, a man called "Marschwald," by the *Chicago Tribune*; "Nassauld," by the *Philadelphia Ledger*; "Norswald" and "Marshwald," by the *New York Tribune*, died in the Brooklyn City Hospital after an illness of three days. His death was attributed to hydrophobia by the newspapers, and so it is said by Dr. T. C. Burnett, house-surgeon of the hospital. The best accounts we have gathered of the case show that the man worked in a tannery and was bitten September 8, 1887, by a Newfoundland dog, kept by the man's employer to drive away thieves. "There was nothing to show that the dog was mad;" but it was killed at once. The wound healed promptly and kindly. As soon as the man was bitten, he went to the City Hospital, where he remained nearly two weeks. Then he came out as cured. He was greatly alarmed about the wound from the bite and visited the hospital every week to have it examined. The owner of the dog, for whom Marshwald worked, said that the man was drunk when the dog bit him, and was trying to hold the animal with one hand. His condition was such that it was deemed necessary to send him to the hospital for treatment for *delirium tremens*. A horse, bitten at the same time, got well. Marshwald kept on drinking, and was in a state of intoxication when he went to the hospital for the last time. On Sunday, November 27, he went to the hospital, saying he was going to have hydrophobia, and showing that he had no hope of recovery.

In the treatment, milk, brandy, chloral, digitalis, and hypodermic injections of curare were given him, and he was confined in a straight-jacket and several men were employed to hold him.

The Diagnosis and Treatment of Lithæmia.

In a paper in the *Medical Record*, Dr. Thomas E. Satterthwait, after giving a brief history of the origin of the word lithæmia, which he ascribes to Murchison, and giving theories as to cause of the group of diseases of that name, gives the following three forms of the disease, with their diagnosis:

1. The hepatic form (hepatic dyspepsia): This variety of lithæmia introduces one at once to the sphere of the digestive functions, in which portal and hepatic congestions play important rôles. Prominent among the symptoms are those of gastric catarrh, distress in the epigastric regions, especially after eating, with drowsiness; acid eructations, a furred tongue and sluggish bowels. Palpitation will occur if the stomach be at any time dilated.

2. In the neurotic form the patient is apt to suffer from neuralgia, frontal headache, tinnitus aurium, a sense of weariness in the limbs, some form of mental aberration, perhaps, such as melancholy or hypochondriasis. Sometimes there are vertigo, muscular cramps, spinal irritations, vaso-motor disturbances, delusions, and, perhaps, epileptiform symptoms.

3. In gout there is as a substratum either of the above forms, and in addition the individual tendency, which is usually, if not always, inherited, to deposition in joints, possibly induced, as Garrod thinks, by the alkalinity of the blood.

Diagnosis.—1. In the hepatic form a diagnosis rests upon the regular occurrence of uric acid in the urine, and especially before the usual acid fermentation takes place upon the deep color of the urine, and its high specific gravity when unaffected by remedies, and by the regular symptoms of hepatic congestion, with its concurrent phenomena, as already described.

2. In the neurotic form, one is only called upon to differentiate it from other organic or functional nervous diseases, in which case the regular occurrence of uric acid in a urine, before the period already mentioned, will indicate the source of the disturbance.

3. In gout the peculiar attacks, affecting, as they do, usually the larger joints of the toes, preceded by irregular cramps and spasms, having a short but violent exacerbation, in which the urine is notably free from uric acid, and followed by sudden and entire relief, while the urine is quickly loaded with uric acid, indicate with sufficient clearness that the affection is gout and nothing else.

Dr. Satterthwaite recommends in the treatment the diminution of the amount of nitrogenous food, but a mixed diet made up of foods which the individual patient can readily digest. The bowels should be freely moved, and for this purpose the natural laxative mineral waters are best. An outdoor life, with active exercise, should be insisted upon, and the patient should be restricted in the use of alcoholic stimulants.

This course of treatment is applicable especially to those of full habit. In other cases a more restricted diet, with rest and a tonic treatment, will be necessary. The author thinks highly of lithia and its preparations, and of strychnia. Dilute nitro-muriatic acid is useful in some cases. Patients should also drink freely of the various carbonated waters.

Hepatic Cirrhosis in Children.

Dr. R. Palmer Howard, of McGill University, Montreal, in a paper read before the meeting of the Association of American Physicians, Washington, June 2, 1887, reported two new cases of this affection, which is rare in children. He states that he did not have an opportunity of seeing the paper of MM. Laure and Honorat, which was published in the *Rev. Mens. des Mal. de l'Enfance*, March, 1887; and that the case reported by Dr. Marsh also escaped his notice. From Dr. Howard's paper, as published in the *American Journal of the Medical Sciences*, October, 1887, the following summary of his study of sixty-three cases is taken:

1. Most of the established causes of the disease in adults obtain also in children, more especially the use of alcohol, which existed in 15.8 per cent. of the whole number of cases. Other causes are syphilis (11 per cent.), tuberculous disease of other organs than the liver (11 per cent.), and, less frequently, venous congestions of the liver, peritonitis, and a general tendency to connective tissue formation in the system.

2. Syphilis occasionally tends to a diffuse interstitial hepatitis or cirrhosis, by first inducing an adhesive inflammation of the portal vein.

3. A general arterio-capillary fibrosis is not proved by these cases to be the usual, and probably not even a frequent, cause of hepatic cirrhosis in childhood.

4. More than half of the cases of hepatic cirrhosis in children do not appear to be produced by the above mentioned well established causes of that affection.

5. There is some evidence that cirrhosis of the liver may be very exceptionally induced by the acute infectious diseases—cholera, typhoid fever, measles, scarlatina; but proof of this is wanting.

6. The habitual use of a stimulating diet, or the absorption of the products of faulty digestion, are probably fruitful sources of hepatic cirrhosis in children.

7. It is in harmony with what is known of the causes of hepatic cirrhosis to believe that the bodies known as ptomaines may be capable of exciting a cirrhotic condition, and

investigation of this subject demands attention.

8. The period of childhood most liable to cirrhosis of the liver is from the ninth to the fifteenth year inclusive; but it may be congenital, and may occur at any age after birth.

9. It is twice as frequent in male children as in female.

10. Its symptoms are essentially the same in childhood as in adult life.

11. It is frequently accompanied by pyrexia.

12. Ascites or icterus, and frequently both together, are of common occurrence in the atrophic and hypertrophic forms.

13. The group of symptoms which have been referred to cholæmia or to cholestæmia, or to acholia, and even sometimes to uræmia, frequently usher in the fatal issue of hepatic cirrhosis in children.

The Treatment of Vaginismus.

The *Glasgow Med. Journal* says that Dr. More Madden, in a paper read on the above subject before the Obstetrical section of the Academy of Medicine in Ireland, January, 1887, gave it as his opinion that vaginismus was generally caused by neuromata occurring in the twigs of the superficial perineal branch of the pudic nerve. Many cases could be cured by forcible dilatation of the vaginal canal and stretching the pudic nerve, combined with general sedative treatment. In some cases Sims' or Emmet's operation might be necessary. In conclusion Dr. Madden pointed out that, even in the worst cases, the condition did not necessarily prevent impregnation.

Hypodermic Injections of Carbolic Acid in Rheumatism.

According to the Vienna correspondent of the *British Medical Journal*, October 8, 1887, Professor Benedict has been using with extraordinary success hypodermic injections of two per cent. solution of carbolic acid in the treatment of rheumatoid affections. He asserts that in even a few months after the injection into the part the joint will be freely movable and free from pain as though narcotized, and in recent cases joints in which there was great tenderness on pressure and distinct swelling of the bones would be apparently free from disease a few days after the injections; not only would the pain disappear in the joints in whose neighborhood the injections had been practised, but would be markedly lessened in distant joints. Professor Benedict believes that the carbolic acid has not only a local influence, but a general effect

in causing the elimination of the rheumatic poison. He has especially obtained good results by the simultaneous use of salicylic and carbolic acids. When the salicylate of sodium is administered by the mouth in small doses, and one to three subcutaneous injections of carbolic acid given in twenty-four hours, the course of the affection was very much accelerated, and no bad consequences were observed, especially if the treatment was carried out from the very beginning of the disease. Extraordinarily good results were obtained by the method in cases of inflammation of the sheaths of tendons, especially after injury. A few injections sufficed to cut short the morbid process, and no local pain or muscular atrophy, etc., was observed, provided the disease was treated in the above-mentioned way from the very outset.—*Therapeutic Gazette*, November 15, 1887.

Darwin as a Medical Student.

In 1825 Darwin was a student of medicine at the University of Edinburgh; but, according to his own account, not a very diligent one. The immediate impression of his studies he describes as follows in his autobiography:

"The instruction at Edinburgh was altogether by lectures, and these were intolerably dull, with the exception of those on chemistry, by Hope; but to my mind there are no advantages, and many disadvantages, in lectures compared with reading. Dr. Duncan's lectures on materia medica at eight o'clock on a winter's morning are something fearful to remember. Dr. — made his lectures on human anatomy as dull as he was himself, and the subject disgusted me. (There are survivors who can fill the blank and recall the memory.) It has proved one of the greatest evils of my life that I was not urged to practice dissection, for I should soon have got over my disgust, and the practice would have been invaluable for all my future work. This has been an irremediable evil, as well as my incapacity to draw. I also attended regularly the clinical wards in the hospital. Some of the cases distressed me a good deal, and I still have vivid pictures before me of some of them; but I was not so foolish as to allow this to lessen my attendance. I also attended on two occasions the operating theatre in the hospital, and saw two very bad operations, one on a child; but I rushed away before they were completed. Nor did I ever attend again, for hardly any inducement would have been strong enough to make me do so; this being long before the blessed days of chloroform."

For Chapped Hands.

A cream for chapped hands, which is far superior to many of the similar advertised products, is made as follows:

Quince seed.....	ʒij
Rose water.....	Oiv
Glycerine.....	Oij
Tr. benzoin.....	fʒij

Macerate the quince seed in the rose water for twenty-four hours. Strain, and add the glycerine and tr. benzoin.—*Drug. Bull.*

Elegant Mouth-wash.

Edina sends a sample of a mouth-wash, half a teaspoonful of which in a wineglassful of water is used to refresh the mouth. It is a pale crimson and transparent solution, with the odor of oil of wintergreen. Its composition is fairly represented by the following formula:

Oil of wintergreen.....	ʒj
Oil of peppermint.....	℥xv
Rose-aniline hydrochlorate[(or magenta).....	gr. ss
Water.....	ʒss
Glycerine.....	ʒiij
Rectified spirit to.....	Oj

Dissolve the oils in the spirit, and the rose-aniline in the water; mix the latter solution with the glycerine, and pour it into the perfumed spirit. Mix.—*Chemist and Druggist.*

Disinfecting Books.

The Sheffield correspondent of the *Chemist and Druggist* says that a fruitful medium for the dissemination of small-pox is afforded by the books of the Free Library. The committee of the library have recognized this, and have ordered the books disinfected. The apparatus employed consists essentially of an oven heated by hot-water pipes communicating with a boiler at the base. At the bottom of the pipes is a copper tray for holding disinfecting fluid. The vapor thrown off by the heat is absorbed by the books, which are thus purified. One hundred books can be disinfected at one time.

Benzol in Whooping Cough.

Dr. John Lowe speaks highly (*Brit. Med. Journ.*) of the efficacy of benzol in whooping cough after the acute stage is past. He gives it in the form of a mixture, of which the following is the formula:

Benzol, puriss.....	℥xxxii
Glycerin, pur.....	f iss
Ol. menthæ pip.....	℥x
Syr. mori (Mulberry).....	fʒss

The dose of this for a child of four or five is a teaspoonful every two hours. The taste of the mixture is not unpleasant. Benzol has the properties of diminishing expectoration and decreasing the spasmodic nature of the cough.

Glassblowers' Syphilis.

The *Lancet* says that Prof. E. De Smet, of Brussels, in lecturing on a case of syphilis occurring in the mouth of a glassblower, referred to several epidemics which have been reported as having occurred among artisans of this description, and remarked that only two plans for preventing these outbreaks had been devised, viz., giving a separate movable mouth-piece to each man, and instituting frequent, vigorous and periodical inspection of the persons of the employés. The first plan is always declared by the workmen to be impracticable, from the loss of time which would be occasioned by fitting the different mouth-pieces on the tubes. The second would, of course, be resisted by the men, but he thinks their objections could be overcome by showing them the danger to themselves and their families, which arises from the present system.

The Value of Cocaine in Obstetrics.

Mr. John Phillips, Physician to the British Lying-in Hospital, after a review of the literature of this subject and a statement of his own experience in the *Lancet*, November 26, 1887, draws the following conclusions: First, cocaine, in whatever way administered, is a valuable adjunct to the treatment of the vomiting of pregnancy, and in some cases is superior to other drugs in use. Second, during the painful earlier stages of labor, especially in primiparæ, it materially assuages the pains, but neither quickens them nor retards their onset, and hence has no effect on the actual dilatation. Third, it is useless in mitigating the pains of expulsion and those caused by pressure on the perineum. Fourth, in the case of sore nipples it relieves the pain attendant on suckling, though the duration of its effects is not sufficiently long to be of material service. It is, however, apparently without any detrimental effect on the suckling.

The Bacillus of Cancer.

The *Deutsche Med. Wochenschrift*, December 1, 1887, contains a paper read before the Medical Society of Berlin, by Dr. Scheurlen, in which he gives an account of his experiments with the cancer bacillus. The following are his conclusions: (1) There exists always in cancerous tumors a bacillus which can be isolated. (2) The spores of this bacillus are met with in all microscopical preparations of cancerous tissues. (3) Inoculations upon animals with pure cultures of this bacillus always give rise to the for-

mation of cancerous tumors. (4) There is consequently a causal relation between this bacillus and cancer.

Eye Affections Treated with Salol.

Dr. Max Thorner, of Cincinnati, reports in the *Cincinnati Lancet and Clinic*, Dec. 10, 1887, his results from the treatment of certain affections of the eye with salol.

Two cases of simple ciliary neuralgia of long standing, one of which had been under treatment for many years, were treated with salol. The first case, of shorter duration, was relieved after the exhibition of the third dose; the second case, of longer standing, resisted the remedy for four days; then relief was gradually obtained and, after the remedy had been used in three daily ten-grain doses for a week, the patient was entirely free from pain, and has had no return of the pain for the last four weeks. This patient has suffered from these pains for over twenty years, the pains being so severe as to confine her to her bed on an average three days out of every week. In one case of rheumatic iritis, in which persistent ciliary neuralgia existed, the remedy was also used. In one case the salicylate of sodium had been used with good effects, but it was discontinued on account of producing gastric disturbances, and salol substituted with great benefit. In the other case the drug was used from the beginning, and checked the pain after the first dose. In one case of acute catarrhal conjunctivitis, combined with severe supra-orbital pain, which relapsed for months in spite of the internal administration of the salicylate of sodium, salol was also given. The salicylate of sodium was discontinued on account of its producing severe tinnitus aurium and deafness, though it never failed to relieve the neuralgia. The result after the use of salol was both a rapid and a permanent one, the remedy having been continued for one week without even producing the annoying complications on the part of the ear, which had deterred the patient from a continued use of the salicylate of sodium. In one case of acute trachoma with ulcerative pannus, in which the pain over and around the eyes was so intense that the patient had been compelled to use daily hypodermic injections of morphia to procure rest, salol was given in ten-grain doses three times a day. The effect was marvelous. After a few doses the patient felt tolerably well, and, although awakened in the night with the severe pain, after taking one dose of ten grains fell asleep within thirty minutes. This prompt action caused the nurse attending this patient to speak of the

remedy as a hypnotic. The repetition of the drug during the day was discontinued after three days, and only one dose was given at bedtime, and repeated during the night whenever a sudden onset of pain caused sleeplessness. The remedy was used in this manner, with the effect of relieving pain and producing quiet sleep, for two weeks, when it was only used whenever the patient noticed an approach of the pain, which, however, seldom occurred.

In most of these cases the dose was ten grains three to four times a day, till relief was obtained. In some cases the single dose was fifteen grains, in others the ten-grain dose was repeated after one hour. At times the patient was ordered to take the remedy whenever indicated by pain. No unpleasant effects were ever observed to follow the use of salol, except slight ringing in the ears in two cases, where the single dose was fifteen grains. But the quantity of salol given within twenty-four hours was rarely, if ever, larger than forty grains, which is far less than the amount usually administered. These small doses of ten to fifteen grains were mostly sufficient in cases of simple rheumatic or neuralgic affections. But even in cases where larger doses are required, the danger of poisoning is apparently not very great, provided the usual caution not to begin with too large a dose is followed. The author does not consider salol a panacea, but advocates the use of it in cases where the salicylate of sodium is indicated, because it is safer than the latter, although in certain cases the salicylate is more effective than salol.

The Treatment of Urethritis in the Male.

In a paper read before the Medical Society of the County of Kings, Dr. H. W. Rand (*N. Y. Med. Journal*) says that for painful urination in gonorrhœa small doses of the oil of sandalwood have given him better results than any other single remedy. He frequently combines ten minims of this oil with two or three grains of extract of hyoscyamus, and gives this quantity two hours after each meal. The effect is said to be more decided when either remedy is given alone. As the inflammatory symptoms subside, the dose of the oil can be increased to twenty or thirty minims, and the hyoscyamus omitted. He also regards the oil of sandalwood as the best internal remedy for the gonorrhœa itself. It is less apt to disagree with the patient than either copaiba or cubebs, and can be given earlier in the course of the disease. When the oil of sandalwood is not tolerated, the tincture of

Cannabis Americana can be given, and will be found a useful remedy. When pain on urinating is very severe, and is not relieved by the means already mentioned, injections of a four per cent. solution of cocaine are useful palliatives, if the act of injecting does not cause too much irritation.

Dr. Rand says that one of the best injections to begin with, which is soothing and at the same time slightly astringent, is the following:

R	Pulv. opii.....	5i
	Aquæ destill. bullientis.....	f3viii
	Mix, filter, and add	
	Liq. plumbi subacetat.....	f3ss

Sometimes a grain of sulphate of atropine may be profitably added to each ounce of this solution. As the inflammatory symptoms subside, the amount of solution of lead in the prescription may be increased to a fluid drachm or more, always bearing in mind that an injection should never be strong enough to produce pain, or even prolonged smarting. Not more than one fluid drachm should be injected early in the disease, but later on three or four drachms may be required to reach all the diseased surfaces. Treatment should be persisted in for at least two weeks after the discharge has entirely ceased.

The Influence of Cold over the Heart in Fever.

Dr. Valke has made a series of experiments upon the action of ice applied to the region of the heart, and extols this procedure in typhoid fever, infectious pneumonia, etc. Numerous tracings of the action of pulse and respiration show that ice applied in this way increases the energy of the heart's action, and acts favorably upon the respiration. The cooling does not lower the temperature of the body, but very probably lowers that of the cardiac muscle.—*Bulletin Medical*, Nov. 20, 1887.

Nervous Phenomena Observed in a Case of Exposure of the Spinal Cord from Syphilitic Ulceration of the Pharynx.

In the *Southern Med. Record*, December, 1887, Dr. A. G. Hobbs reports the case of a young man who was brought to him in October, 1886, supposed to be suffering from ulcerated sore throat. He had been a cowboy in Texas for two years, and had been strong and robust, weighing 140 pounds. When he applied for treatment he was thin, pale and anæmic, weighing only 104 pounds.

He denied ever having had syphilis, nor had he any evidence of this disease, other than an ugly sloughing ulcer about the size of a silver quarter-dollar, in the posterior and superior wall of the pharynx. By the use of a soft palate retractor a direct view of the greater part of the ulcer could be obtained. A bent probe discovered necrosed and detached bone at a depth of about half an inch, a piece of which was extracted at the first sitting. At each succeeding daily visit for two weeks small pieces of bone, from the size of a pin head to a small pea, were either washed out with the cleansing syringe or extracted with the probe or scoop. The index finger could then be inserted into the cavity as far as the first joint.

The treatment had, from the beginning, been based upon the assumption that it was a syphilitic ulcer, notwithstanding his repeated denials of ever having contracted the disease, and his father's assurances that he had been healthy from infancy, and could not, therefore, have inherited the taint. He began on forty grains of iodide of potash, three times a day, in a menstrum of *Succus Alterans*. This dose was afterwards doubled. The ulcer was daily cleansed with cotton probes, syringing and sprays. Sprays were applied not only directly, but through the nose, on account of the discharge being partly expelled through that channel. Listerine was used for its disinfectant and cleansing properties, and nitrate of silver, full strength, was applied to the bottom of the cavity by a cotton probe, after which the cavity was packed with iodoform. About this time—after four or five weeks of daily treatment—the nervous phenomena first occurred. For a week or ten days he had been complaining of constant pain in the back of his head and neck, which caused him to carry his head rigidly to one side. He was also unable to sleep, except for a few minutes at a time, and in a sitting posture. After the cavity had been thoroughly cleansed at one of the treatments, the nitrate of silver probe was pressed to its bottom, when, as suddenly as if he had been shot, one-half of the patient's body became paralyzed; his head fell to the right, his right leg turned outward, and he would have fallen from the chair if Dr. Hobbs had not caught him. Without losing consciousness at any time, this hemiplegic condition lasted about thirty seconds, when, as he expressed it, "he felt a tingling in the right half of his body," and in another half minute he slowly raised his right side into position. The next day the same phenomena were repeated, *but on the opposite*

side. He was now so reduced in weight (to ninety-six pounds) and in strength by the loss of sleep and constant pain, that he could not walk to Dr. Hobbs' office. The extreme insomnia lasted about ten days, during which time his attendants thought he did not sleep one hour in twenty-four. The pupil of the side affected became slightly dilated, but there was apparently no change in the perspiratory glands while the paralysis lasted. But from this time healing began at the bottom of the ulcer, the discharge became less, and examinations with the finger did not discover any more rough bones; he slept better, and complained less of the pain in the back of his head and neck.

A week passed on with all of his symptoms gradually improving when, the author says, he could no longer resist the temptation of making another pressure with the probe. Paralysis of the side which was pressed upon, was again exhibited, but in a much milder degree than before, ending in the same tingling sensations as described before. As only the spray and powder-blower were used from this time onward in dressing the cavity, no more pressures with the probe were made till healing had well progressed—probably ten days or two weeks after the test. The author was then surprised to find that when the probe was now pressed into the cavity a condition just the opposite of paralysis was exhibited; the arm and leg jerked and jumped as in a case of chorea. These choreic muscular contractions, unlike the paralysis, lasted only during the pressure of the probe. In repeating the probe pressures at intervals during the next few days, the same choreic symptoms were produced, always on the side corresponding to the pressure, but in a less and less degree, requiring a still firmer pressure to produce the effect.

Finally, when the healing process had been thoroughly established and cicatricial tissue had, in a measure, closed up the cavity, only a "tingling and prickling" sensation followed the probe pressure—a sensation similar to that which followed the hemiplegia in the first instance. After the cicatricial tissue had thoroughly hardened, no manifestations followed the pressure of the probe. Dr. Hobbs says that ten months after the patient was first seen he had entirely recovered, and presented a perfect picture of health. His weight was thirty to forty pounds more than he weighed in November of 1886. He was kept on a lessened dose of iodide of potash and Succus Alterans until July, 1887.

Food and the Nursing Woman's Milk.

Zalieski's conclusions upon this subject, as stated in *Le Bulletin Médical*, November 20, 1887, are as follows:

1. Woman's milk, which is very rich in fat, can have an injurious influence upon the development and the nutrition of the child.

2. A food very rich in albuminoids increases considerably the proportion of fat in woman's milk, and causes a corresponding diminution of the sugar. The other constituents of the milk are not sensibly altered. It is very possible that alcoholic drinks have the same action as albuminoid foods.

3. The composition of the milk can be told from the manner of life or the food of the mother or nurse, which is a very important matter in the favorable development of the child.

4. The kind of food has an influence upon the composition of woman's milk, exactly as it does in animals.

5. The fat of the milk is formed mediately and immediately, and probably in its greatest quantity, by virtue of the albuminoid substances of the food.

Œdema of the New-Born and Phlegmasia Alba Dolens.

At a meeting of the Academy of Medicine of Paris on November 15, 1887, M. Dumas (*Progrès Médical*, November 19, 1887) spoke upon the probable identity of œdema of the new-born and phlegmasia alba dolens. He thinks the former should not be confounded with sclerema, for it is characterized by the infiltration of serum into the subcutaneous cellular tissue and into all the cellular interstices of the affected parts. On the contrary, this œdema should be regarded as a symptom of phlegmasia. Treatment should consist, (1) in the employment of heat in the form of the brooding-hen (*couveuse*) of Tarnier; (2) in the absolute condemnation of manipulation of the affected parts, which was recommended until then by all authors, as it tends to the formation of emboli.

Effervescent Citrate of Lithium.

Citrate of lithium.....	10 parts
Bicarbonate of sodium	30 "
Tartaric acid.....	20 "
Sugar.....	20 "
Sugar of milk	20 "
Alcohol.....	40 "

Mix the solids, in fine powder; dampen and knead the mixture with the alcohol, rub through a coarse sieve, and dry.—*Am. Druggist*.

Lead Poisoning from Flour.

The *British Med. Journal*, December 3, 1887, says, that a very remarkable epidemic of lead poisoning has recently been investigated in three communes in the north of France. Upwards of one hundred persons were suddenly attacked with violent symptoms, among which severe colic predominated. So serious did the condition of some of the sufferers become, that medical aid was obtained, and the presence in several patients of a characteristic blue line on the gums gave rise to the suspicion of lead poisoning. The water supply was derived from so many different sources that it could not be incriminated, and suspicion ultimately fell on the flour. It was ascertained on inquiry that the affected persons had all obtained their flour from the same mill, but those who had partaken of rye bread were most severely attacked. The mill was gone over, and after a long and painstaking examination, attention was directed to the tin buckets of the elevator which served to transport the rye flour from the grindstones. Several of these buckets had a dull, leaden appearance, and were found to have been "tinned" with lead. As doubts were entertained whether the quantity of lead from this source was sufficient to give rise to such severe symptoms, they were carefully weighed, and were found to have lost upwards of 150 grammes of their weight. The wheaten flour, which passed through another elevator, was free from lead, and this was evidently due to none of these "leaded" buckets having been employed in its construction. The accuracy of the discovery was confirmed by the observation that those who ate rye bread exclusively were most severely attacked, while the others, who mixed the two flours, escaped with comparatively slight symptoms.

Is Cancer Contagious.

Mr. Charles E. Jennings, F.R.C.S., who has given much attention to the question of the contagiousness of cancer, writes to the *Lancet*, October 29, 1887, that he does not think cancer is a contagious disease in the ordinary sense of that term; but that if it is ever transmitted, transmission is effected by grafting—the process being comparable to the well-known method of skin grafting. He, therefore, regards the recently reported case in which a man became affected with cancer of the penis after having for a long time carefully nursed his wife, who was suffering from cancer of the uterus, as simply a remarkable coincidence. The same opinion is expressed with regard to the case reported

by Mr. Adam, in which a physician married a lady who subsequently developed cancer of the uterus and mamma, of which she died. The physician, a short time afterwards, became himself affected with cancer of the stomach and liver. Before his death, however, he married again; and a year or so later this second wife was under the necessity of having both mammae removed for cancer, in successive operations, as a result of which she died.

Sublimate Paper as a Surgical Dressing.

Filter paper prepared in the following way has been found useful as a surgical dressing. It is first steeped in a solution consisting of sublimate grs. 3, glycerine $\mathfrak{m}$ 75, and water $3\frac{1}{2}$ oz., and then dried. It is not alone useful in small superficial wounds, but even large wounds and major operations may be dressed with this material.

From personal observation Gedeke, *Centralblatt für Chirurgie*, comes to the following conclusions:

1. That filter paper saturated with a $\frac{2}{10}$ per cent. bichloride of mercury solution makes a good material for surgical dressings.
2. That according to the size of the wound, from a single layer up to eight ply should be used, and the whole held in place by a dry bandage.
3. That such a dressing is particularly adapted to fresh wounds.
4. In complicated injuries of the fingers, this dressing has the advantage of acting as a splint as well as a dressing.
5. It should be changed every two or three days.
6. When other antiseptic surgical dressings cannot be had, suppurating wounds can be kept aseptic for a short time with this dressings.—*Pacific Med. and Surg. Journal*, Dec., 1887.

Effervescent Carbonate of Lithium.

Carbonate of lithium.....	10 parts
Bicarbonate of sodium	.30 "
Tartaric acid.....	.20 "
Sugar.....	.40 "
Alcohol.....	.40 "

Reduce the solids to a fine powder; mix thoroughly; dampen and knead the powder with the alcohol; then rub it through a coarse tinned-iron or hair sieve, or through an enamelled colander, and dry it, first at 68° F., then at 104° F. Separate the somewhat coherent mass by cautious pressure, and preserve in well closed vessels.—*Am. Druggist*.

News Items.

—Dr. William G. Wright, of New York, who fired several shots in Clinton place on the night of October 19, after a quarrel with Paul Jardine, a commission merchant, was arraigned before Recorder Smith, Nov. 28, for examination as to his sanity. Drs. Trual and Field testified that Dr. Wright was a sufferer from general paresis. He had delusions as to his wealth. The jury found him insane, and Recorder Smith sent him to the State Hospital for the Insane at Poughkeepsie.

—Dr. H. H. G. Piffard, of New York, has been making some interesting experiments in orthochromatic photography with the instantaneous flash. The magnesium was found to be too white a light, and he made a "golden orthochromatic compound," with which he has obtained remarkable results. A print was shown at the Philadelphia Amateur Photographic Club recently from a negative made in this way. The subject was a bunch of chrysanthemums, yellow, magenta, etc., and the color values are reproduced in the most perfect manner.

—The position as medicine man to a band of Indians at Bay Centre, on Shoalwater Bay, in Oregon, is about being vacated, and a competitive examination was at last accounts being held for a successor. The examination was unique and in accordance with the laws of the tribe, which provide that the candidate who dances for one week, night and day, without giving out, and succeeds in the meantime in finding some object which has been previously hidden, is chosen. He is forthwith declared the medicine man, and the "healing business" is turned over to him. When last heard from, the candidates had been tripping for four days, and several were almost exhausted.—*Phila. Ledger*, Dec. 6, 1887.

—Dr. William A. Hammond appeared in the Tombs Police Court, New York, December 1, as complainant against George A. Scott, whom he charged with criminal libel. Scott makes and extensively advertises an electric corset and belt, and in the advertisement appears this passage, which Dr. Hammond characterizes as libelous: "Every mail brings us testimonials like the following: 'The celebrated Dr. W. A. Hammond, of New York, formerly Surgeon-General of the United States Army, lately lectured upon this subject and advised all medical men to make trial of these agencies, describing at the same time most remarkable cures he has made, even in cases which would seem hopeless.'" Dr. Hammond denies that he ever used the

articles in question, and says that the statement in the advertisement is false, fraudulent and intended to injure him in professional and other circles.

—Revolt in a Hospital. —The *Progrès Médicale*, November 12, 1887, states that a terrible revolt has broken out in the Hospital of Santa Maria, at Naples, which is occupied by several hundred women who have venereal diseases. They commenced by driving the nuns from the convent and forcing them to take refuge with the police. They then sacked the hospital, breaking in pieces and throwing everything out of the windows. Armed with table-knives they attacked the police, who had to force the gate. A platoon of soldiers and some riflemen were called upon, but hesitated to employ brute force against the women and were repulsed. But as they were assailed by chairs, plates, bottles, bars of iron and broken bedsteads, they marched against them with fixed bayonets and drawn swords. The revolt lasted eight hours, and twenty-two sisters, as well as several of the soldiery, were more or less seriously hurt. Twenty-eight of the most desperate women were arrested. The principal cause of the revolt was the prohibition of visits to the hospital, as it was found that lovers were received in place of parents.

—Dr. Edmund Andrews has written a letter to the *Chicago Tribune*, December 6, in which he describes the pathology of cancer, on the theory that it is dependent upon a bacillus. He has couched his description in terms intended to be understood by laymen; and we think has made his exposition so clear that it will alarm some of the readers of the Chicago newspaper referred to:

"The world swarms," he says, "with numberless species of microscopic fungi, called in a general way microbes, of which the bacilli are one group. They are everywhere present, especially in all decaying substances, in stagnant waters, and in the dust of the air. They are blown about on all winds, seeming in the dry form as dead as thistle-seeds do in their aerial flight, but when they light on moist surfaces, or fresh wounds, for instance, many of the species germinate and multiply by billions, and some of them cause the putrid diseases commonly grouped together under the name of 'blood poisoning.' Some of them possess the power of swimming in fluids, and when they light on a wound leading into the sac of a joint, or other delicate interior cavity, they make their way into the inner spaces and set up there a decomposition of a poisonous and deadly character."

—A Pasteur Institute has recently been set on foot in Constantinople, where it is expected a large material will always be on hand on which to practice. An institution in which the treatment of persons bitten by rabid animals will be undertaken, has also been founded in Barcelona. A wealthy merchant of that city gave a large sum of money for the purpose of founding a hospital similar to that of M. Pasteur. The city added largely to the sum, so that as to include within one building the Pasteur Institute, and a laboratory for bacteriological and histological investigations. The whole will be under the directorship of Ferran, of cholera inoculation fame, who will himself perform the anti-rabies inoculation.

—Something akin to emotional insanity is set up in the defence in the case of Weidler, charged with shooting a Brooklyn physician (referred to in an editorial in the *REPORTER*, July 2, 1887), and two doctors have testified that the man was insane at the time of the murder. He is clearly sane enough now. His insanity he attributes to malaria, and he alleges that his mind was blank for some time after the fatal day. The murder itself was extremely deliberate. Weidler lay in wait for the doctor and shot him repeatedly in broad daylight. It is possible that the jury may be sufficiently soft-hearted to accept the plea of insanity for that occasion only. If they do, it will be a direct encouragement to the use of the pistol, and cannot but have an unwholesome effect.—*N. Y. Tribune*, Dec. 2, 1887.

HUMOR.

DIAGNOSIS.—A friar once met some medical students, who asked him, "Do you know the difference between a friar and a jackass? Give it up?" "Yes, I give it up." "Well," said they, "one wears a cross on his breast and the other on his back." "Now," said the friar, "do you know the difference between a medical student and a jackass?" "No," said the students. "Neither do I," said the friar.

"How is it that you charge me fifty cents for this little pinch of bicarbonate of soda when you gave three times as much for ten cents yesterday?" Druggist: "We are filling a prescription to-day. Suppose we are going to translate Latin for nothing? My dear sir, you don't seem to appreciate what it costs to obtain a classical education. Hold on! I've given you oxalic acid. That boy's always shifting them bottles around.—*Boston Transcript*.

A LADY, who had been severely bitten, once went to Abernethy, and knowing his aversion to hearing unimportant details from his patients, merely uncovered her arm, and held it up before him in silence. After looking at it, Abernethy asked: "Scratch?" "Bite," said the lady. "Cat?" asked the doctor. "Dog," she said. Whereupon the gruff doctor broke out: "Zounds, madam, you are the most sensible woman I ever saw in my life!"

A MATTER OF FAMILY PRIDE.—"Prisoner, have you anything to say why the sentence of death should not be passed upon you?" "A few words, your Honor. I am thirty years of age." "Well?" "Your older brother is a physician." "This is impertinent and irrelevant." "It may sound so, your Honor, but it means life or death to me. I understand that you take a great pride in the phenomenal success of your brother?" "I do, but what possible bearing can that have upon your case?" "Simply this: Your brother, the doctor, examined me a year ago and predicted that I would live at least thirty years. It would certainly undermine his reputation as a scientist should I die before that time."

—A MAN MET his doctor on the street and complained of rheumatic pains, for which the doctor recommended him to take a pinch of "nitrate of potash" two or three times a day. Shortly afterwards he met the doctor again, and, in reply to a question regarding his health, remarked, "Oh, I'm getting well, doctor; but 'tain't your medicine. I tried that for some time, till a neighbor told me of something he took for his rheumatism—a very simple remedy. I tried it, and it does me a great deal of good." "What is it?" said the doctor. "Oh, it's simple: I'm afraid you'll laugh at me if I tell you." The doctor promised to control his risibles, and the patient, after much urging, informed him that it was "saltpetre." The doctor's smile was longer than the street.—*Chemist and Druggist*.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Dec. 18, 1887, to Dec. 24, 1887:

Capt. Victor Biart, Assistant Surgeon, relieved from further duty in Dept. Dakota. S. O. 293, A. G. O. Dec. 17, 1887.

First Lieutenant Eugene L. Swift, Assistant Surgeon, ordered for duty at Fort Spokam, Wash. Ter. S. O. 293, A. G. O. Dec. 17, 1887.
